The drive leading to the principal entrance, and which is shown in the illustration (fig. 57), is of noble proportions, and is worthy the most splendid conceptions of its great designer. The curving sweep upwards towards the point shown in the left foreground of the picture is of magnificent scope, and is far superior to the majority of those seen in different places. Standing close to this point is a bronze figure, of a favourite horse of the late Baron de Rothschild, which was designed and executed by the great sculptor Boehm. This monument rises, as it were, from a groundwork of Pampas Grass, whose waving plumes must produce a charming effect on a pleasant day. This model forms a really striking feature from several points in the surrounding pleasure gardens. On the right of the drive as one approaches the mansion, and not shown in the photograph reproduced, there is a flank of various trees of different habits, amidst which stand conspicuously, like sentinels, upright Junipers and Cypresses. Many splendid trees are to be observed at intervals hereabouts, but some of them are largely obscured by their strong growing and less attractive neighbours. Thinning has been done, and will have to be still further practised, but Lord Rosebery has an aversion to the felling of trees and their removal, so that Mr. Smith has to proceed with judicious caution. A narrow path branching from this drive leads the visitor to the "cottage in the wood," wherein the Baron and Baroness de Rothschild lived during the time that the mansion was being erected. It is a charmingly secluded spot, embowered in trees, where no sound could come save the song of birds and the sighing of the wind through the trees.

The Laurel Banks.

Though the appearance of our illustrations does not perhaps suggest the fact, the mansion of Mentmore stands on a somewhat lofty rise, whose sides fall away sharply on at least two sides of the house and gradually elsewhere. In one position there is a slope of grass, but the great features are the Laurel banks that cover an immense area of ground and which must contain hundreds of thousands of individual plants. I have seen something similar before, but never on such a gigantic scale as this. All the surfaces are kept quite smooth, and the labour of cutting them over must be very considerable. In some places they are quite level, while in others they fall at a sharp angle, but everywhere there is the same regularity. These form cover for rabbits innumerable, and a few were caught sight of scurrying across the path as we made our journey round; the whirr of the pheasant's wing as the birds rose in flight for the parkland was frequently audible, both telling of lively sport in their proper time and season. The incline from the lower grounds to the terraces and mansion between the Laurels is very steep, and our advance was not particularly rapid, as will be understood when the slippery state of the grounds from frost and snow is borne in mind.

The View from the Terrace.

There was a time when the ground immediately at the foot of the slope beneath this terrace was devoted to parkland, but some score or so of years ago a portion was enclosed for the extension of the pleasure grounds. Under the fostering care of Mr. Smith this area has been developed until at the present time it is a charming adjunct to the gardens that were previously not of commensurate extent with the mansion and estate. However it is not to these that reference would be particularly made just now, but rather to the magnificent pastoral panorama that is spread before the

eyes. One might aptly quote the words of the famous Roderick Dhu to FitzJames when he said—

... where lay,
Extended in succession gay,
Deep waving fields and pastures green,
With gentle slopes and groves between.

We must, however, to appreciate the whole scene go beyond the valleys and, allowing the eye to follow the rising of the ground, find the view terminate in the Chiltern Hills. This noble range forms a fitting background to a piece of typical scenery, than which none need seek a fairer in all the broad acres of England. On these hills is situated, as is comparatively well known, Halton, the residence of Mr. Alfred de Rothschild, and on a clear day a glimpse of the estate can be had from Mentmore. The intervening space is beautifully wooded, as all real English scenery should be, and one's eyes may roam for miles without meeting any incongruous object, or any semblance of a thing to mar the harmony of the whole.

The Fountains Garden.

On this terrace too, and also bounded in the distance by the Chiltern Hills, is an enclosed formal garden that takes its title from the fountains it contains. It is entered by a broad flight of stone steps, and the illustration (fig. 59) will convey a sufficiently clear conception of its extent and formation. The month of February cannot possibly be regarded as an ideal time to see such a feature as this. There it is true are the bold beds, but they are destitute of those plants that contribute towards making them so beautiful at a pleasanter and more genial period of the year. It then, one can readily conceive, forms a most desirable feature that is likely to elicit admiration from every visitor to Mentmore. Already preparations are being made for its adornment during the coming summer, and in their winter quarters may be found thousands of plants whose destination will be the Fountains Garden when the proper time for their insertion is with us again. Naturally the design is formal, but no one need cavil at this,

Photo by Theo Piggoit.

Lettyton Durrant.

FIG. 59.—MENTMORE: THE FOUNTAINS GARDEN.

for when the eye tires of the formality there is always the view beyond to afford change and repose and add zest to the beauties of the garden that have not yet been seen.

The Italian Garden.

Of far greater extent than the foregoing, and probably even more beautiful in the summer time, is the adjacent Italian garden, whose bronzes, statues, and vases are now encased in wooden shields that have

little of the beautiful but much of the useful in their construction. An admirable view of this garden with the mansion in the background is afforded by the illustration (fig. 61). It will be at once observed that as in the case of the previously mentioned Fontains Garden, this is sunk, and entrance is made by broad stone steps. The design adopted in the laying out of beds is decidedly elaborate, and as the beds are of considerable extent, the number of plants required to efficiently stock them is enormous. Though termed the Italian garden, doubtless from its shape and the inclusion of statuary, it has in the Box edgings to the beds and scrolls something of the Dutch character. These are several inches high and wide, and have an old world look beside the known age of the mansion. One can with difficulty picture in the mind the charm of this garden, and I for one shall live in the hope that I may see it and its neighbourhood at the zenith of their beauty at some future time. But we must press on, as there is still much remaining to which reference must be made, and even then justice will scarcely be done to the varied glories of Mentmore.

The Subtropical Garden.

The pleasure grounds or gardens of Mentmore are literally crowded with features of interest and beauty, and amongst them must be classed the subtropical garden. This, as is the case with the flower gardens, is essentially a feature of the summer, but for the winter one might well change the name to pinetum, as it is rich in shapely handsome trees of many choice kinds. As an addition to the pleasure grounds in the summer the subtropical section ought never to be omitted, as from its position and the type of plants one should use therein, it affords a cool retreat that is entirely different in its essential characteristics from every other part of the garden. No portion will, as a rule, be more appreciated or more admired, but it is, of course, necessary to adhere rigidly in stocking it to plants that will assist in maintaining the name as correct. In the shady nooks between stately Conifers may be found ideal spots for a handsome Palm or a noble Dracena, while for the beds cut out of the soft green turf we have the Cannas, the Ricinus, the Wigandias, and many others that will suggest themselves to the practised mind. The illustration (fig. 58) depicts a single curve in the subtropical garden at Mentmore, and though one may readily gather that it is a place of beauty and interest, the picture fails to do real justice to its undoubted charms. Even on that cold and frosty morning in February it was singularly beautiful, though its attractiveness was lent by the frost-laden trees, and not the pure and simple subtropical plants. At one of the entrances to this garden, and at intervals within its confines, may be seen numbers of Bamboos, which thrive remarkably. Considering the truly perpetual handsomeness of well grown specimens, it is to me a matter for constant surprise that Bamboos are not employed far more extensively than is the case at present. They are, however, growing steadily in favour, and will eventually be seen with pleasing frequency.

The Rose Gardens.

Though the enthusiastic rosarian growing for exhibition produces blooms of surpassing magnificence, there is no place in which Roses are grown where they appear more at home, and receive more general admiration, than in the Rose garden. This, of course, is provided the enclosed has been judiciously chosen and skilfully planted. It must

have a situation that, while it is to a degree protected, has unobstructed light, and where the probability of the greedy roots of forest or other trees penetrating the garden and robbing the legitimate occupants of nourishment is reduced to a minimum. There must further have been the presence of a master hand or mind in its formation, as an over-intricate design, or even too much rustic work, might easily rob the whole of beauty. I have in mind a Rose garden admirably chosen as to site, and skilfully laid out, that is spoiled by the over-prodigious use of young Pines to form rustic arches for the climbing Roses. True this particular garden is yet in its infancy, and the softening hand of time will do much to tone down the naked obtrusiveness of those pillars and arches.

Needless to say, in forming the garden at Mentmore everything that care, skill and deep knowledge could do to insure success was done, and with the happiest results. This is another feature that must be seen in the summer to appreciate its worth. But one Rose garden is

apparently insufficient to meet all the requirements of the estate, and consequently a second is in course of formation at the present time. This is being especially prepared for the accommodation of 4000 French Roses, and the garden to be in keeping with the varieties in it will be laid out in the French style. An excellent position has been selected with a very gentle slope, and after the work of levelling is completed the beds will be formed with interspaces of grass. At the foot of the garden a belt of shrubs is being planted, and down each side there will be a broad border for herbaceous plants. The whole will be finished this spring, and in a season or two will have to be reckoned amongst the many varied charms of the estate. As has been the case with the almost numberless other improvements, the planning and arrangement of this have emanated from the mind of Mr. Smith, and are being adopted with the entire approbation of his noble employer. The formal design in this garden will be in direct contrast to the freer English style.

The Aviary and Hardy Fernery.

In immediate contiguity to both these gardens are a large aviary and a hardy fernery. We had a brief glance into the former, and saw many birds of strange form, and in some cases brilliant plumage. They have a commodious, and, apparently, congenial dwelling place amidst the trees, and no doubt many visitors wend their way to this spot to see these denizens of other lands that have become acclimatised to our own fair country. In the hardy fernery there was nothing to be seen save the snow, with here and there a brown frond lying ragged and exposed. It is thus not possible to give any particulars of its formation from my own experience, but it will not be out of place to reprint a brief description that was furnished to the *Journal of Horticulture* many years ago. The writer there says:—"Proceeding we pass a hardy fernery pleasingly formed in a nook in the woods, the very place in which Ferns delight. It is surprising what can be done with a few loads of soil and stones thrown up under trees in a series of irregular mounds with curving paths between, when taste and good judgment are exercised in the arrangement. Here the Ferns have been planted in groups of species and varieties, not the whole regularly dotted and mixed in a weak diluted manner that should never be seen in ferneries of this nature."

FIG. 60.—MENTMORE: OLD MANOR.

A Tree with a History.

On an estate of such acreage as Mentmore it is usually safe to assume that there will be several kinds of soil, and it frequently happens that trees which will thrive in one position barely exist in another. To a degree this is the case here, but, generally speaking, all kinds of trees grow remarkably well, and if they do not make rapid advance at first they easily make up for it later when the roots have become thoroughly established. Then they grow speedily and strongly and attain to considerable stature in the course of a few years. Evidence of this can be seen on every hand, and hundreds of specimens that Mr. Smith planted are now handsome, tall and strong. It is

sown, and two years later (March 25th, 1880) the plantlet was placed in its present home. To-day it has a height of considerably over 30 feet. The Countess of Rosebery has long since passed to her eternal rest, but her memory remains to-day as green in the minds of men and women as the stately tree that was planted on her bridal day.

The Village of Mentmore.

Proceeding from the essentially ornamental and beautiful portion of the estate to the still beautiful but more utilitarian section, we pass through the village of Mentmore. It is ideally situated with splendid views on every hand, and one has not traversed a dozen yards ere incontrovertible evidence is seen of the presence of a thoughtful owner.

FIG. 61.—MENTMORE: THE ITALIAN GARDEN.

not desirable in such notes as these to give lists of plants or flowers or trees, and I shall therefore take one species as being typical of many others. For this purpose we may choose *Wellingtonia gigantea*, which is seen in many positions and everywhere in splendid condition. Two specimens measured by Mr. Smith have a height of 37 and 35 feet respectively, with a spread of branches of 50 feet. We may, however, make for the moment the selection still narrower, bringing it down to one example of the species, as this tree has indeed a history. It stands with a few others in a plantation close to Mr. Smith's house, and has been grown from seeds sown by him many years ago. The cone containing the seeds from which this plant was raised was shot with a rifle from a tree in California by a medical friend of the late Baron de Rothschild, and reached Mr. Smith two weeks prior to the Earl of Rosebery's marriage to the daughter of the house. On the day of the wedding, March 20th, 1878, the seeds were

The clean and tidy houses have an air of comfort that is unfortunately lacking in many an English village, and the gardens attached, though not now containing much produce, will doubtless in due season be made to bring forth their share of food for the homes. The schoolhouses have, too, an aspect of prosperity that is quite in keeping with the surroundings. The allotments provided for cottagers I did not see, but the system of working and their extent are, I know, much above the average, and many surprisingly excellent crops are gathered therefrom. From either end of the comparatively short village street there are magnificent views of fertile valley to rising ground beyond, while to the right passes the road to the town of Leighton. From several points hereabouts glimpses can be had of Mr. Leopold de Rothschild's garden of Ascott, but the residence cannot be seen because of the trees by which it is surrounded. These, too, naturally obscure any details of a garden that has a wide repute for its beauty.

The Fruit Gardens.

At a point where the Leighton road makes a sweeping curve we find a pair of gates that gives upon the gardens devoted to fruit and vegetables. The former are of great extent, and it is superfluous to say space is found for all kinds of hardy fruits. The number of Apple trees is enormous, and all the best varieties in cultivation are represented. The bush trees were of particular excellence, and were models of the best type. Each growth was literally studded with fruit buds, and every branch had sufficient space for its growths to receive the utmost benefits derivable from sun and air. A variety of superlative merit was found in long rows extending right across the broad quarters, while others of lesser value had more limited attention accorded to them. Practically the same system is adopted with all other kinds of fruits, and all alike look peculiarly thrifty. Bush fruits, as including Gooseberries, Currants, and Raspberries, with the all-important Strawberries, receive attention commensurate with their importance. The spaces between the fruit trees are not at Mentmore, as is often the case elsewhere, cropped with vegetables, but are requisitioned for the accommodation of Daffodils, of which there must be hundreds of thousands of bulbs.

The Vegetable Garden.

In an establishment of the magnitude of Mentmore the vegetable department is an exceptionally important one, for not only have the supplies to be constant, but also large. A small quarter of a popular product, like Celery for example, would be practically useless, and consequently a large breadth of ground has of necessity to be devoted to it. And indeed this is practically the case with all the vegetables grown. It need not, therefore, be said that the vegetable gardens are extensive, and are managed under such an excellent system that the possibility of a failure in the supplies has been reduced to a minimum. It cannot be stated that when this visit was paid the whole of the ground was stocked, as such could scarcely be the case. There were nevertheless several valuable crops, and active preparations were being made for the complete cropping of the land immediately the proper time for doing so is with us. The photographic reproduction (fig. 62) does not do the garden justice, but it shows the range of glass (which has been previously noted as visible from the railway), with the village of Mentmore beyond. Of course the walls surrounding this garden are fully occupied by fruit trees trained in various forms, and these, like the bush specimens, are given the most skilful attention. This department may be a little neglected on some estates, but such is not the case at Mentmore.

Fruits under Glass.

With the exception of the dome-roofed structure in the centre of the range the several houses seen in the illustration are devoted to Vines, Peaches, and Nectarines, and it would be no easy matter to find a better type of house for the important crops named. They have sufficient height without being unreasonably difficult to manage; they are three-quarter span-roofed, and afford the occupants an abundance of unobstructed light, while ample provision is made for ventilation and for heating. The Vines vary in condition at present, some being well started, others with the rods depressed, more still dormant, with some in one house carrying fruits which will, doubtless before the moment of writing, have been removed. Mr. Smith thinks very highly of the comparatively new Appley Towers for late use. The Peaches and Nectarines present about the same appearance as the Vines, but in this case there was naturally no crop of ripe fruit, though there was an abundance of flowers. The whole of the stock was in splendid condition, as were the structures themselves, everything being scrupulously clean. The earliest Vines are in pots in a small but lofty house of a much more old-fashioned type. Here the healthy young canes were in vigorous growth, and carrying their full share of bunches, the earliest of which showed that the thinner had been at work. A long, low, pit-like range provides accommodation for Pines, and handsome the plants looked in their sturdy health. It is fortunate that those luscious fruits still find a place in some gardens, when they have been ousted from such large numbers. All other fruits receive attention proportionate with their importance, this being, of course, governed by their acceptability at the mansion.

The Plant Houses.

The major portion of the glass houses are placed in one small garden by themselves, where are also situated numbers of valuable frames. Amongst the several structures space is found for growing all sorts of flowering and foliage plants, both for affording cut flowers and

for providing material for the embellishment of the mansions at Mentmore and in London. Plants are mainly grown in large collections, the greatest amount of space being accorded to the most favoured, with reductions according to recognised importance. The greater proportion of these houses are long span-roofed, and rather low, and are admirably adapted to the purpose for which they were designed. There are in addition several houses of much greater dimensions for various plants, for which the other structures are not suited. One of these, for example, is very lofty, as it must be, for the tall Palms used in the mansions require considerably more head room than the lower houses could possibly provide. This department like all the others is splendidly equipped, but it may be safely asserted that its capacities are sometimes strained to the utmost to fulfil the demands made upon it.

The Bothy and Garden Rooms.

From the young gardeners' point of view the bothy is one of the most important adjuncts to a garden, and considering the hours that journeymen have to spend therein, one cannot be surprised that this is so. Many of the buildings employed for the housing of the young men are a positive disgrace, and if the new erection at Mentmore were taken as a standard model for adoption in all gardens we should hear no more complaints on the part of young gardeners of improper accommodation. It is a commodious two-storied structure of red bricks and tiles, and the rooms are light and of splendid size. There are excellent kitchens, washhouses, and pantries, while a bath was also to be fitted in a spare upstairs room. It is certainly one of the most complete bothies that we have had the pleasure of inspecting. The other rooms, sheds, and houses attached to the gardens are very numerous, and comprise special places for fruit and flower packing, Grape rooms, and hardy fruit rooms, Mushroom houses, tool and potting sheds, and so on through the whole list of such conveniences.

The Man in Charge.

For slightly over a quarter of a century these important gardens have been in the charge of Mr. Jas. Smith, and during the whole of that period improvements have been in progress or contemplation. Everything that care and skill could do has been done, so that the money at disposal should be wisely spent and not be frittered away on alterations that could bring no ultimate benefit to the estate. Mr. Smith is known and respected throughout the entire world of gardening, and besides being an active member of the Fruit Committee of the Royal Horticultural Society, is one of the original sixty Victoria medallists of honour. Mr. Smith lives in the old manor house of Mentmore (fig. 60), in which he presides as a quiet, yet genial host, and wherein both he and Mrs. Smith offered much appreciated hospitality on the occasion of this journey to see Mentmore and its beauties.—ZINGARI.

The Freemasonry of Gardening.

IN that fellow feeling which makes the whole gardening world kin, there are not only many pleasing traits, but more helps to workers and their work than the outside world is aware of or even imagines. True it is that the links which form this great chain of brotherhood are invisible to the public eye; yet, nevertheless, do they make a stronger girdle, probably, than more conspicuous ties in any other phases of life ever do, for they are forged by the great hand of Nature herself, as a common bond to those who are in constant communion with her. "You gardeners are too clannish," a gentleman once remarked, "you always appear to isolate yourselves from other men in other stations of life." That is so. Few will dispute it, though many cannot understand it. Nature is a jealous ruler, and one of her unwritten commandments is, Thou shalt have none other mistresses but me; hence, outside their own sphere of work gardeners find little to attract them, and against that there is a strongly felt, if unseen, magnetic influence confining them to their own orbit of duty. Rarely indeed does a single unit fly off at a tangent for absorption by other spheres of labour or recreation; and the gravity of a gardener's life remains practically undisturbed by the most exciting of outside influences. Glorious "clannishness!" Splendid "isolation!" Be it our endeavour here to analyse, to encourage and promote its growth until what is to some more or less visionary may be to all a forcible, living reality.

To be simply a gardener carries with it the presumptive rights and

ostensible privileges of *entree* to the gardens of the United Kingdom; probably far beyond, over that Empire on which the sun never sets, and we trust never will. A few exceptions, possibly, there are; if so, they are few and far between, for the writer has never knocked at a garden door that was not opened unto him, and he was welcomed inside. Invidious as it may appear, an employer is often precluded by some social barriers or strangership from entering a garden whose door stands open to his man unless he, too, should belong to the great order of gardeners (in the broader sense); then, as such, all barriers disappear. As gardeners, in the more comprehensive sense of the term, the peer and the pound a week man may for the nonce join hands, and, as a matter of fact, such has actually occurred on one occasion at least. Many old heads, of course, well understand these matters, which are more often thought about than talked about. It is for the benefit of younger and less experienced men they are now given expression to, which, *apropos* of visiting, will in due course include some unwritten rules of *etiquette* it is unwise to ignore. It may be said of some liberal-minded patrons of gardening that not only do

the herbaceous border. Hopes his visit is not inconvenient; a truce to all covenances and conveniences—is he not a “gentleman,” a gardener, and a brother? Aye, and always will be, whether we rise or fall in the gardening world.

Of such is the genuine gardener; but there is another class of visitors, gentlemen, too, needing but not always accorded equal rights and privileges in the gardener’s freemasonry, for in spite of its elasticity under the genial warmth of friendship’s glow, it quickly contracts in the colder atmosphere of commercial elements. Judiciously combined, however, it is often a mixture of pleasure and profit. Some commercial travellers take this compound interest in the gardener and all his works. They are, generally, old hands with long heads, literally interpreting the adage, “no profit is where is no pleasure ta’en.” Younger men “on the road” might do worse than follow in their footsteps. This gentleman, whether his approach is heralded by her Majesty’s mail or not, who invariably comes laden with a neat valise or portfolio and a good fund of commercial logic, often finds that the gardener’s heart does not go out to meet him. No matter how

Photo by Theo Piggott.

Leighton Buzzard.

FIG. 62.—MENTMORE: THE VEGETABLE GARDENS AND FRUIT RANGE.

they love their gardens but love gardeners too, according to them the warmest of welcome on their visits. Still, there is a good deal of surreptitious visiting, for the British gardener is often a modest, diffident man; one who, while anxious to see, would rather not be seen, and the better the man the more anxious does he appear to creep under a bushel of reserve.

With worker and fellow worker all reserve is cast to the winds, and the gardener stands out in his best light, anxious to learn and ready to teach. There are no special signs or grips, although a gardener’s grip is intensely characteristic in the freemasonry of the craft, and the only passport required is to be a gardener. Never let any man of any other trade, profession, or vocation pose for what he is not, in order to gain admittance to the Eden of his imagination. He will be detected at a glance, for the recognition is intuitive. Let the veriest stranger stand within one’s garden gates, and ere a word is spoken he is weighed in the balance of mental observation, and received accordingly. “A gentleman to see you; he is waiting on the far walk.” A gardener we suppose (all gardeners are gentlemen, or should be). We are *en deshabille*—viz., *en* shirtsleeves, and they rolled well up, consequently to the ordinary visitor, of whatever degree, “not at home.” Naked, but not ashamed at being thus caught by one of the craft. “On the far walk? All right, be there in a minute.” That minute’s grace is sufficient to test the standing of our visitor, for he is already fidgetting on “the far walk,” and critically poking his eye through

peaceful his appearance and tactics you feel that he is on the warpath, and, unless invested with the power and will to give an order, the feeling is an uncomfortable one. Well do we remember how, many years ago, two capable men, representing two of our largest trade concerns, arrived much to their chagrin by the same train, and how by a little diplomacy we switched one on to the other in showing them round, safely despatching them by the next without any canvassing for that order we were not prepared to give. One cannot fail to admire the tact and ability which many business visitors display in extolling their wares, nor fail to feel regret that persuasive eloquence ranging “from grave to gay, from lively to severe” should go unrewarded.—E. K., Dublin.

(To be continued.)

AN AMERICAN INNOVATION.—The Illinois House of Correction is about to try an interesting experiment in the reformation of women criminals. Supt. Sloan has built three large greenhouses, covering a space of 4000 square feet, in which it is intended to grow Roses, Carnations, and Chrysanthemums for the Chicago market. The women prisoners will work in the greenhouses under the direction of an expert horticulturist, and it is expected that contact with the growing plants will have a softening and regenerating effect on the hardened natures of the unhappy inmates of the institution.

A Chat About Work Among Roses.

MARCH is a busy month with the rosarian, who must be up and doing in order to give a good start to his favourite trees, from which he hopes for such fine results during the glorious days of summer. Any planting which has been unavoidably delayed ought to be completed as soon as possible, for although the soil is moist enough now, it is quite possible we may have a dry spring and early summer; such times are always very much against late planted trees of any kind. When late planting is done extra care should be taken to insure good results. After the roots are shortened, if they are in the least dry, immersion in water for a few hours is of great benefit; then with care in planting and mulching with short manure one feels for a time quite satisfied as to results, but should very dry weather occur in May the enthusiast will generally find the means to water, and thus bring to a successful issue the work which was begun so well.

The pruning of Hybrid Perpetuals and other hardy Roses must undoubtedly rank among the most important operations needing attention during March, and when the operator is armed with a keen-edged knife and a stout pair of gloves there are few more pleasant tasks connected with the art of gardening. To secure fine blooms worthy to grace the exhibition table hard pruning must be resorted to. Cut back boldly to within one or two buds of the base of each strong shoot, and remove weak ones entirely. When this system is practised we get abundance of strong shoots each year. In time they become too strong if the plants are not periodically lifted, but then that work is a necessary part of the system for supplying fine blooms. Once in three or four years the bushes ought to be lifted, the ground trenched and thoroughly manured. Hard pruning and plenty of manure may be termed the cardinal points in growing first-rate Roses on dwarfs.

Let us now turn to the consideration of Roses grown in beds purely for garden ornamentation. Some like to see beds filled with good full bushes, laden with numbers of flowers; very hard pruning there is not necessary. For the first year or two the strong shoots sent from the base may be left from 6 to 9 inches in length, weaker ones pruned to two or three eyes. In time less vigorous growth is made, and as the bushes increase in height they may be shortened regularly to two or three eyes, with the exception of very weak shoots, which should be entirely removed. A few worn out branches will each year need cutting away to make room for strong shoots springing from the base, such strong shoots to be left from 9 inches to a foot in length. When treated in this way constant vigour is maintained, and if no disbudding is practised a wealth of beautiful medium-sized flowers is obtained which make the heart glad by their brilliancy and profusion during the sunny days of June.

What a pity it is that the Moss Roses are not more generally grown, for who does not admire them when their pointed buds peep through the crested greenery? Some of the stronger growing varieties succeed admirably if pegged down, the side shoots being pruned closely each year, and a few of the old shoots to be replaced by strong young shoots. In other instances after the foundation of the bush has been laid, it is not wise to prune hard, as the beauty of the flowers does not lie in their size; a profusion of pretty buds is what all wish to secure, and this object is attained by moderate shortening of the shoots.

Arches and pillars of Roses are the glory of many a garden, and although their time of beauty is only a fleeting one, the impression lingers in the memory, even after the summer has passed and the chilly days of autumn come. The climbing Cluster Roses are especially suitable for covering arches and rough buildings, as their growth is so rapid, their management so simple, and their floriferousness so certain. Cover an arch with Crimson Rambler and Climbing White Pet, and then behold at blossoming time truly a thing of beauty. After pruning newly planted stock closely to lay the foundation, the knife need scarcely touch them for a year or two; rapid progress is then made, and the allotted space soon covered; till then only a few unripened shoots need cutting away. But when a dense thicket is formed thinning requires practising each year. I like to examine the trees when the flowers have faded, removing a good deal of the small wood which has flowered, so as to make room for young shoots to be trained in loosely during summer. Some of the very strong shoots I stop, or clip with the shears, to prevent them from "robbing" the weaker ones.

With arches so managed there is not much pruning to be done

now, only a few unripened points to remove, and a little dead wood or useless scrub to be cut away. But either during summer or in spring such attention is necessary, to keep healthy growths covering the whole space. In training avoid anything approaching formality, tie sufficiently to keep the main branches secure to the arches, but let plenty of shoots hang loosely in all directions, then when wreathed with Roses they will be picturesque indeed. Aglaia (Golden Rambler), Euphrosine (Pink Rambler), and Thalia (White Rambler) are other fine varieties in this section. Do not forget to treat these Ramblers liberally, they will repay the trouble. Remove a few inches of the soil, give a coating of rich manure, and cover with soil—fresh loam. If the arches are near lawns or walks roll back the turf for a few feet, stir the soil, and add manure, then the trees will go on satisfactorily each year without showing signs of age or decay.

The pretty miniature Polyantha Roses are charming for small beds, or for edging larger ones, and as they make compact bushy growth little pruning is necessary. Thin out the shoots here and there, sometimes cut away an old branch, and wiry looking little bushes will be formed. Perle d'Or (orange), Cecile Brunner (pink and yellow), and White Pet, are favourite varieties that all should grow.—H. D.

A Note on Pruning.

THE question of pruning Roses is constantly being brought forward, and many excellent articles have been written on the subject. The interest in the queen of flowers is, however, so great, that one may turn again to the subject without fear of opposition, and in the certain knowledge that, to inexperienced amateurs at any rate, the remarks are sure to be welcome. Where only a few dozen Roses are grown the whole may be pruned in one day; but where they are cultivated in large numbers, or by hundreds, they should be pruned at two or three different times, as this will be the means of securing a much longer succession of bloom.

We have Rose beds in several portions of the pleasure gardens. Some of these are in very sheltered positions, while others are considerably exposed, and those most sheltered are pruned first. Those attended to first are producing strong shoots, which will be well advanced before the latest have formed any leaves, and in this way we may not be able to have a great number of blooms at one time, but they will be coming in for many weeks, and this is what is most desired by all who have a constant supply of cut flowers to provide. The second blooms, which are always much valued, generally come in August and September, sometimes in October, and the time of pruning in spring has much influence on the last Roses as well as the first.

When Roses are not in leaf at pruning time, none of us seems much afraid to cut them well down; but when the shoots are 2 or 3 inches long, as many of them will be soon, it is with regret, if not fear, that they are cut. In consequence many of the shoots are left much longer than would otherwise be the case, and the result is that many of the plants have very long bare stems at the bottom and a bushy top, which is neither very ornamental, nor productive of fine blooms. Dwarf Rose bushes are very liable to assume this form, and if they are to be useful pruning must not be spared. Every stem, whether it has the appearance of starting into growth near the ground or not, should be cut down to 2 or 3 inches from the soil, and after this, although they may be a little longer in starting, it will be surprising where the number of young shoots have come from, and it will be still more astonishing when it is seen the improvement which will take place with them before the end of the season. We treated many plants in this way last season, and the results were satisfactory in the highest degree.

Marechal Niel for Walls.

The beautiful and popular Maréchal Niel has had some attention of late, and I should like to refer to the fact that it can be grown on a south or west wall out of doors, and a good plant growing under favourable conditions is an object of rare beauty. It is a climbing plant, essentially worthy of having some special treatment. It is a good plan to take out the soil of the border 2 feet deep where it is proposed to plant the Rose, and if the soil is very light it may not be necessary to put in any drainage, but if the subsoil is clayey we should excavate 6 inches deeper, and put 9 inches of brickbats at the bottom, and over this a layer of turf, grass side downwards. The border ought to be made at least 3 feet wide, and should be twice as much long. The soil should be turfy loam, fresh if you can get it, chopped up roughly, and to this add a fourth of well decayed manure, thoroughly incorporating it with the soil. Procure a plant on the Briar, budded close to the soil, and a year from the bud. Do not have an old stunted plant, they seldom do any good, and those that have been grown under glass and highly fed, so as to make a sappy shoot of 8 or 10 feet length in a season, and in a small pot, are not worth having at a gift. Plant so that the whole of the stock is covered with soil, making the latter firm about the plant. Mulch the roots with short manure, and give water if the weather is dry. A strong plant will bear scores of magnificent blooms.—ROSARIAN.

Reminiscences of An Old Florist.—No. 5.

AMONGST those figures who loomed large in the horticultural world some forty or more years ago, and with whom I had a good deal to say, was John Standish. He was conspicuous in every way, and when one saw his burly figure and genial countenance coming into any place of meeting, one was sure the meeting would not be dull. It was under his auspices, I believe, that Robert Fortune paid his second visit to Japan, and when he had been sending home the treasures he had collected I was with Standish at Bagshot when they arrived. There were flowering plants, shrubs and bulbs, and his sanguine temperament made him see everything in its most rosy aspect. He put up a number of tiffany houses to shelter his plants, but unfortunately the breezy downs of Bagshot were too exposed, and some of these came to grief.

This was just before the opening of the Royal Horticultural Society's gardens at South Kensington, and as Messrs. Veitch & Sons had also their collector in Japan in the person of Mr. J. G. Veitch, both of these eminent firms were anxious to get their productions there for the opening day. There was one plant especially to which much attention had been attracted, as it was believed this would create a great sensation. Messrs. Veitch and Sons won the race, and were rewarded by the great crowds which clustered round their plant during the whole of the day. It was thus that *Lilium auratum* (the golden rayed Lily of Japan) first came before the British public. I believe the first bulb sold was purchased by the late Mr. Sigismund Rucker for £15 15s. Since then what thousands, I may say millions, have been imported from Japan, and what a rich harvest the clever nurserymen of those islands have reaped from it. Still there is a difficulty experienced in growing it, which nearly all cultivators have felt. I say nearly all, because now and then one does come across a vigorous clump. As a rule growers treat it more like an annual, they go to the auction marts, buy a quantity of the bulbs, but they never expect to see anything of them again after the first year; some they may grow for themselves, and others they dispose of.

There is another flower in which Mr. Standish took a great interest at one time, the *Gladiolus*, but he had a very curious notion concerning it; he believed that the poor heathy soil of Bagshot was especially adapted for them, and in fact recommended for their cultivation that where the soil is not poor enough it should be burnt. Experience has proved how utterly wrong this was, for they thrive best in the rich unctuous loam of Cambridgeshire and Somersetshire. Mr. Standish raised a number of seedlings, some of which he distributed, but they were never of any great value, and they would cut a sorry figure alongside of the splendid blooms which we are now in the habit of seeing in the metropolis raised by Kelway, and Burrell.

When Roses first began to come to the front and new varieties were beginning to reach us from France, Mr. Standish's attention was attracted to them, and being acquainted with Mons. Le Roy of Angers, and hearing that his foreman, Trouillard, had been engaged in raising seedlings, he determined to go and see for himself what they were. It was somewhere in the sixties that Standish determined to go to France, and as I was much interested about Roses, he asked me to accompany him. What a jolly time we had of it! We stayed in Paris and visited some of the principal nurserymen there; thence we went on to Tours, passing through the beautiful and historic country of Touraine, and at last reached Angers. The result of this trip was that Standish had the satisfaction of exhibiting in the Hanover Square rooms that grandly coloured Rose, a seedling of *Géant des Batailles*, Eugène Appert. I do not think that in colour it has ever been excelled, while its foliage, so beautifully dark and velvety, added considerably to its merits. Its shape, however, was indifferent, and now it is very rarely seen. But there was another Rose which we saw there that has proved to be a great acquisition—*Celine Forestier*. This was purchased and distributed by Mr. Standish, and as a garden Rose is greatly valued. Its delightful colour and floriferousness give it a great claim on the lover of a garden; yet it is not an exhibition Rose. Nevertheless I have seen some very creditable blooms of it in exhibition stands. Standish was very anxious himself to raise some good Roses, never succeeding, however. One he raised which he called Canon Hole, but it was not up to the mark.

John Standish always brings to my mind another very keen florist, the Rev. Joshua Dix. He was an enthusiastic angler, and many a day's fishing did Standish procure for him. Though he was a great lover of angling, he was also a great lover of a garden. Before I came here he officiated as the curate of the next parish, and some friends of his resided in Westwell. They, too, were lovers of the garden, and many were the choice plants that their friend used to procure for them. It was on their house that there grew the finest plant of Cloth of Gold Rose I think I ever saw. The first year that I saw it, it had from 200 to 300 flowers,

and it was a sight worth going many miles to see. The house itself belonged to a neighbouring landlord, and when the ladies died his gardener was let loose upon the place to alter it, and I may say to spoil it. The poor Cloth of Gold was cut down! and so thoroughly resented the insult that it never flourished afterwards. Moreover, the perpetrator of this Gothic act never seemed to think he had done anything barbaric. Mr. Dix was also a great lover of the *Gladiolus*, and tried to make the flower more popular by getting up a special exhibition of it. I have, however, digressed a good deal from my journey to France with Mr. Standish.

Le Roy's nursery was at that time, and I believe is still, celebrated for his wonderful collection of Pear trees. The climate of Angers was, of course, favourable for them, and as we went through the gardens we saw magnificent specimens of the most celebrated varieties. Surely an immense number of the collection were utterly useless; and, after all, it is not on the 400 or 500 varieties on which Pear growers' attention is fixed, but on a comparatively smaller number of selected sorts. At that time Camellias were very much in favour, and there was one grower at Angers—Mons. Cachet—who had a collection of very beautiful plants; I believe they were grown entirely in the open air, but were placed during the summer between high evergreen hedges, the brilliancy of their foliage being unsurpassable. It is singular how fashion changes! at that time no more grateful present could be made to a young lady going to a ball than a bloom of a white Camellia; now the Rose must take its place.

On our way back from Angers we stopped in Paris and visited together some of the more famous nurseries around that capital. They compared very unfavourably with those of our own metropolis, and even as far as the Rose nurseries were concerned there was always disappointment. A thunderstorm had occurred, and the Roses were all spoiled! This we were told so often that we began to think thunderstorms were ordered on purpose. Amongst those visited were Thibaut and Keteleer, where we were most hospitably received, but in no garden did we see the signs of lavish expenditure that meet us in many of the grand establishments about London. After we had finished our brief but pleasant journey to France, I had many talks with Mr. Standish, and discussed his various plans, some of which, to say the least, were visionary. Amongst these may be classed his ideas of rushing Strawberries to early market. He proposed to start an express between Ascot and London, to be run by post horses, the relays of which were to be placed all along the route. Like most enthusiasts, he never saw any difficulty in the way! they were all brushed aside as unworthy of consideration. He was one of those men whose worth it is always pleasant to remember. I am always thankful that I was enabled with the assistance of many friends to have his portrait and that of his friend, Mr. Dix, placed in the Council room of the Royal Horticultural Society. It may be that before long they will have a more appropriate place than that which they at present occupy. But I wondered at that time whether either of them would be remembered, or whether they would share the fate of that marble bust that used to be in the conservatory of South Kensington, and which when the Society removed from that ill-omened place no one could be found to tell whom it represented.—D., Deal.

Gardening in the Sixteenth Century.

Our Earliest Writer.

THOMAS HILL is said to be the earliest English writer on gardening. The date of the first of several editions on "The Profitable Arte of Gardening, &c.," does not seem quite clear. The Hon. Miss Amherst, in her "History of Gardening in England," mentions his first work as "A most briefe and pleasant treatyse, teachynge howe to dress, sow, and set a garden," A.D. 1563; and adds, "A second edition is unknown." In a list of his works at the end of another edition, described as being "the thyrde time increased," A.D. 1568, he mentions that of A.D. 1563 as having been "encreased by me ye seconde tyme." To this third edition, of which I propose to give some account, is added "The Physicke Helpe" to each of the plants described. Having no previous English authorities on gardening, Hill was obliged to go back to the ancients, and gives a list of some twenty or more Greek and Roman writers from whom he compiled his work.

Old English Garden Plans.

A woodcut of a garden gives an idea of what prevailed from the earliest times to the seventeenth century, when landscape gardening came into vogue. It consisted of a rectangular enclosure made by walls, palings, or shrubs with trees, in which a well and an arbour were recognised necessities; the beds were laid out in rectangular forms with paths between them. He also gives two

designs of mazes, one circular and the other rectangular,* which seem to have been favourite structures in his day. He describes the best position for a garden as facing E or S., and away from barns and stables, in order to avoid chaff. The nature of the soil should be well studied, so that "naughty and filthy sand and gravel" may be avoided. "A quicke sette hedge" should enclose it, and he recommends sowing the seeds of Brambles and Briars, as the "wilde Eglantine."† The seeds should be mixed with meal of tares and pasted or smeared over a tarred rope laid in a trench and then covered over with earth.

Each border, called an *area* by the ancients, was devoted generally to a single kind of plant. There were culinary vegetables and drug plants, though the former were supposed to have their virtues as well; So Hill gives the "physicke helpes" of each one. Few flowers were grown for their own sake, though many had their own virtues, such as Roses, Violets, Marigolds, and others.

A contemporary French writer under the name Carolus Stephanus‡ (who also compiles and follows the Roman writers), gives an *area* devoted to flowers used as chaplets and garlands, of which the ancients made much use. Indeed others than young women bore chaplets; thus Chaucer describes the sompnour§ among the Canterbury pilgrims as having "a garland set upon his head."

Sowing Lore.

In sowing seed the age of the seeds should be carefully noted, as some grew better when young, others when old; and he suggests a plan of sowing several kinds in one hole, so that a *single* plant would bear many sorts of flowers!

Astrology comes in occasionally as the phases of the moon indicate the proper periods for sowing; since "seeds might not grow through some malice of the celestial bodies." Hence a paragraph is devoted to the proper time of sowing, according to the position of the moon.¶ It runs as follows:—"The moone beyng betwene the 28 degree of Taurus and the eleventh of Gemini, sowe. And the moone beinge between the 28 of Gemini and the 6 of Cancer, sowe not," &c., &c. As no one is likely to pay any attention to these directions now, I will spare the reader the remainder!

Watering should be done in the morning and evening with lukewarm water; and if the well be deep the water should be exposed to the sun for a few days before being used. Manure may be mixed with the water.

With regard to making of arbours Hill writes:—"After the newe digging and turning up againe, the garden must then be garnished with herbers before the quarters and beddes be cast out and devised. And you maye make these herbers, either straight running up, or els vaulted or close over the head like to the vyne herbers nowe a dayes made."

A wholesome warning against trusting newly procured seeds is given:—"You may not put your whole hope, that vndoubtedly they wyll prospere, in that it is doubtfull whether they wyll prosper, or no."

Combating Garden Pests.

The animal world seems to have been very annoying, if the numerous remedies against injury by them be any indication. The following are a few examples:—Steeping seeds in the juise of House-leek is recommended, as it makes birds intoxicated! Worms should be smoked out of their holes to prevent them gnawing the roots of herbs. If Roket (Rocket?) be sown among plants flies will not come near them. Sharp vinegar with henbane juice sprinkled upon the herbs is a good deterrent to insects, or the water of Fleabane and Nigella. As for caterpillars, the trees should be sprinkled with bloody twigs, or hung with river creauisses (cray-fish). The smoke of brimstone and Garlic leaves, or Squill bulbs hung about, also keep them off.

To keep moles away, Palma Christi, or Tickweed (Castor-oil plant) and Walnuts full of brimstone chaffe and rosin put into their hole, stopping up all other holes, they get choked by the fumes. An "easy manner" is as follows:—"Get a quicke (live) mole, putting the same into a deepe earthen pottle, set onto the edge into the earthe, which mole. . . wil crie out, and after the other moles in that ground do thus heare him crie, they will hastily drawe neare vnto him, and minding to help him furth, wil so fall into the pot." To keep ants away, smere the stems with oil of Lupines, or put the heart of an owl into the ants' nest, when they will be driven away. Remedies against mice, adders, gnats, breezes (whiche bee flies that eate the

corne as it groweth), and others are given, more ridiculous than sensible.

To destroy "rust when it is falling on the herbes" pungent smoke from burning horn and dung, blown by the wind upon the plants, is recommended; or water in which the wild Cucumber or Colocynth has been bruised, should be sprinkled over the plants. This last is interesting as foreshadowing the modern method of spraying with various fungicides.

Garden Stock of Sixteenth Century.

"The Seconde Booke instructeth the diverse maner of sowynge, setting, and ordering of the moste potherbes, flowers, &c., with the care and secretes taught." To each follows "the physicke helpes."

The following are nearly all the plants mentioned as being the most important to be cultivated in a garden of the sixteenth century. *Potherbs*.—Lettuce, Endive, Succory, Spinach, Orache or Arage, Beet, Coleworts, Asparagus, and Mallows. *Kitchen Herbs*.—Cress, Savory, Lovage, Anise, Cummin, Coriander, Dill, Mustard, Fennel, Pennyroyal, Rosemary, Cnervil, Lavender, Rue, Hyssop, Mint, Thyme, Marjoram, and Basil. *Flowers*.—Roses, Violet, Marigolde, White Lily, Wood Lily, Iris, Peony, White Poppy, Gillyflower, Carnation, Borage, Bugloss, Germander, the Blessed Thistle, and Purslane. *Kitchen Vegetables*.—Artichoke, Leek, Onion, Garlic, Great Garlic, Radish, Navew, Parsnip, and Carot. *Fruits*.—Melon, Cucumber, Gourd, Strawberry, Bean of Egypt*. A few others not readily identifiable complete the list.—GEORGE HENSLOW.

Chamærops Fortunei.

ALTHOUGH this handsome Palm will endure a great amount of cold it does not flourish out of doors everywhere, and where it will not its appearance is anything but what it ought to be. My experience with it dates to many years back, when I became the possessor of half a dozen medium-sized plants. A portion of them I brought forward in pots, the remainder were planted out in a cold pit. They remained in that pit about two years, when three or four of them were planted out, two in small circular beds on the turf in a tolerably good position, but not sheltered from winds, and I soon found the tips of the foliage became browned and useless. Though this was by degrees replaced by other foliage the plants still presented a crippled appearance, only a portion of the base of the leaf remaining, and the points being all destroyed.

Of course the progress of the plant is slow; but one which had a more sheltered position, being planted on a south border amongst Yuccas and Irises, where the wind had little chance of injuring it, flourished. Although we subsequently had some rather severe winters after it was placed in this position it never showed the least injury either from wind or frost, and looked as well as other plants of a like kind in pots in the greenhouse. It is a slow growing plant, and consequently may not be a general favourite, but it must be remembered that its appearance is good at all times, and if grown at all it ought to occupy the favoured position undisturbed for at least half a dozen years.

As a sort of Oriental poetry attaches to the name of Palm, a species that survives an English winter must at all times be interesting. Patience is the only requisite in its culture to insure success, for this plant cannot be multiplied like the ordinary occupants of the flower garden; indeed, I have never been able to increase my stock by any other means than from seeds. The quality of these must not be too hastily condemned, for they are very irregular in germinating. On one occasion, when I procured seeds, I placed each one in a separate pot at the beginning of February, and put these receptacles in a very warm pit. If my memory serves me truly, none of the seedlings came through the soil until May. Some came up at various times during the summer, the last one appearing as late as November, or at least nine months after sowing.

Thus it will be seen that it is unwise to hurry the plant, which when well grown is such an attractive addition to the garden. Of course it is very largely used in subtropical gardening, for which purpose it is admirably adapted; but in this case, as with many other occupants of this department, it spends the winter under glass, and only comes out of doors during the genial days of the summer. On this phase of its culture I need say nothing, as it is thoroughly understood, and my object in writing this note is simply to encourage its trial (where such has not already been done) as a permanent occupant of suitable positions in the flower garden or other desirable places.—R. J., Devon.

* This is reproduced by Hon. Miss Amherst, Op. Cit., p. 119.

† Eglantine in the fourteenth century was the Dog Rose, but the name was transferred to the Sweet Briar in the sixteenth.

‡ His real name was Charles Estienne (see "The Praise of Gardens," by Sieveking, p. 43).

§ I.e., a summoner or apparitor.

¶ So Virgil says: "Even the moon has made different days lucky for work in various ways." (Geor. I.).

* Faba egiptiaca was Colocasia antiquorum (Schott), but was also a name for the Lupin, which is probably meant here.

Parsnips.—It was said the other day at the Drill Hall that the superb samples of Tender and True Parsnip shown by Mr. E. Beckett were of the Student variety. But the true Student, or in any case the variety that is in commerce as the Student, has raised necks and not hollow crowns as Tender and True has. To satisfy critics Mr. Beckett sent me samples of both varieties, and I find them to be exactly as stated. Tender and True seems to have been a white and more refined selection from the old Hollow Crown. It is a delicious variety, the flesh being very soft and marrowy, whilst the roots as a rule are less coarse than are those of the Hollow Crown. Tender and True Parsnip is to be grown with others at Chiswick this year, that its distinctness may be tested.—A.

Giant Onions.—As the outcome of a little talk the other day as to the keeping qualities of giant Onion bulbs, Mr. Beckett has kindly sent me along from Elstree a few samples of his splendid bulbs of last season's growth to show how his have kept. These bulbs, of perfect form and finish, and varying from 1½ to 2 lbs. in weight, are as hard as nuts and certainly would keep well in a cool dry place till the end of April at least, yet they have been ripe and pulled since the middle of September last. That there are wet cold seasons when giant bulbs do not finish off well or keep well there can be no doubt, but even small or ordinary spring-sown bulbs are similarly affected. No one must conclude henceforth that giant winter-raised Onion will not keep well if fully matured.—A. D.

London's Almond Trees.—After referring to the swelling buds of the Almond trees in the London suburbs and dilating upon their popularity, a writer in a contemporary proceeds:—"Though originally a child of the East of Asia and the North of Africa, the Bitter Almond, or *Amygdalus communis amara*, came into this country more centuries ago than anyone can tell. As far back as the eleventh century it was a favourite with high and low, under the delightful name of Easterne Nutbeam, and our good old gardening friend Gerard tells us that in his time Almond trees were 'in our London gardens and orchards in great plenty.' Thus it has gone on blossoming before any other shrub or tree, and taking with its graceful bloom the harshness from our harsh month of March; decking itself with foliage as decorative almost as that of the Ilex, and standing, each autumn, with its harvest of egg-shaped, velvety fruit, which gapes when ripe, throws its 'nutte' lavishly on the ground, and goes contentedly to sleep. Come snow, come frost, come storm and flood and stress, with death and destruction to other imported plants, the Almond survives them all, and justifies in its adopted country as well as in its Eastern home, the reputation implied in its Hebrew name, Shakad—i.e., early awakening."

Bonemeal for Vines.—It is doubtful whether the value of bone-meal is fully recognised for application to Vine borders as a surface dressing. Last season I saw some old Vines treated to a fairly liberal application, and the numbers of roots that were attracted to the surface were remarkable, as were others which issued from the main stem on the border line. Bonemeal enters largely into the composition of some prepared manures, and no doubt with pot plants it has a beneficial action in inducing root activity. In the case of Vines, however, it would not avail much in attracting roots to the surface, unless some provision is made to assist their progress when formed. A dressing of decayed manure and fresh soil would furnish this, and give the roots something agreeable in which to burrow and at the same time to feed upon. Active surface roots are always held as a sign of satisfaction on the part of the Vine, and such a response to the treatment given cannot be otherwise than gratifying to the grower. I was so impressed by the action of bonemeal in the case under notice that I resolved to give it a similar trial, not only to Vines but other fruit trees, as an alternative to other specially prepared dry manures. I remember some years since, when fish manure was so freely used, the quick response there was in surface roots from Vines. I do not know whether there is any standard quality in bonemeals, or if the same results can be expected from every preparation. It may not be so.—R. A.

Blue Gums.—Reading the English papers one finds occasionally an article referring to something with which we in New Zealand are more familiar than the writers, and they amuse us a little. For instance, some time ago someone spoke of "Blue Gums" *Eucalyptus* as trees that "shed their bark instead of their leaves." That they shed their bark is undoubtedly correct, but they could give any deciduous tree you ever heard of points, and then beat them at leaf shedding. They are evergreen, of course, but are shedding leaves every day in the year, particularly in summer, when dry weather compels them to relieve the strain, and the ground beneath them is always strewn. In this respect they are rivalled only by Pines, notably insignis and maritima, and the "Karaka" *Corynocarpus levigata*. --W. H. T.

The Witch Hazels.—The pleasing sight of a cut branch profusely laden with the attractive and curiously composed flowers of that winter-flowering Witch Hazel (*Hamamelis arborea* syn. *japonica*), actuates me in attempting to draw increased attention to this most desirable species. The flowers are produced in pairs on separate stalks, two of which latter spring from a bud on the ripened wood. Unlike the Japanese Allspice (*Chimonanthus fragrans*), and the Carolina Allspice (*Calycanthus floridus*), the flowers of the Witch Hazels are unfortunately devoid of appreciable scent. The Virginian species (*H. virginica*), produces its flowers in the autumn, and its fruits ripen in the spring time. In conclusion it may be interesting to remark that the name Witch Hazel is due to the supposed virtues of a forked twig as a "divining rod."—G. W.

Trees for Different Soils.—The experiences of our most successful foresters go to show that trees are just as particular in the matter of soils as are almost any other plants. Some delight in deep loamy land, others are at their best on thin shallow soils, on which, under ordinary circumstances, a deep-rooting plant would be expected to find the greatest difficulty in maintaining an existence. Among the trees which do best on very shallow soils are, says a contemporary, the Spruce, the Mountain Ash, the Birch, and the Mountain Pine. Soils of medium depth are best suited for the Alder, the Beech, and Austrian and Weymouth Pines. Soils which are deeper still are required for the Scotch Pine, the Silver Fir, the Elm, Maple, Ash, and Lime; while the Larch and the Oak are capable of producing the best results only where the roots are given an opportunity of penetrating to a very considerable depth.

Blackberries in New Zealand.—A correspondent writes from Wellington, New Zealand:—"I was interested in reading an account in the Journal of Blackberry gathering in Australia. We do some of that. At a place called Kaitoke, over thirty miles from here, at the foot of the Tarrarna Ranges, is a valley where Blackberries luxuriate. To get there for blackberrying it is usual for parties to go in vans, each having a pair of horses, for though the railway is near the spot it would not be convenient for the purpose. I have been several times, principally, however, to see the Ferns. We leave here about six o'clock on Saturday evening. Eight miles of the journey winds around the western side of our harbour, then through a flat fertile valley, or rather two, called respectively Lower Hutt and Silverstream, and Upper Hutt. This part of the journey is about twenty miles. Lower Hutt contains our two chief nurseries and most of the market gardeners who supply Wellington with green vegetables. After getting out of the valley we ascend a small mountain (Mungaroa), around the spurs of which the steep road winds in a fashion quite alarming to newcomers. Up this we have to travel on shank's pony for nearly an hour, then dip down to the Pankuratchi (pronounced Pokrati) river. A further slight ascent is negotiated, and we are at our destination. The time, about 1 A.M. We next gather logs, which are abundant, make a fire in the open air, boil billies, and make tea. After supper, those who can manage it wrap their coats about them, and stretch out near the fire for forty winks; no one gets much more, for I must tell you that the nights here are always cold. Daylight shows the Blackberry bushes hanging on the steep sides, and dotted about the bottom of a snug valley beneath us. How they came there originally I do not know. There they are, and there is the fruit, bushels of it. About three hours of work will gather 70 lbs. of selected fruit, gathering none but the ripest and best. We start for home again in the evening. The Blackberry ground is, as I said, in a valley, perhaps I should have said gully, less than half a mile long, but is at a considerable elevation above sea level—I do not know exactly, but I suppose about 1000 feet. It is subject to frequent rains."

Zonal Pelargoniums.

THERE are two methods of establishing a collection of single and double Zonal Pelargoniums. The better system, where there is no stock of good varieties to fall back upon, is to consult the catalogues of those nurserymen who cultivate the best and newest varieties, as new and improved sorts are constantly being added to the cream of the older varieties. Good varieties are as easily cultivated as indifferent ones, hence when they are cultivated in quantity for decoration and cutting, also bedding, endeavours should be made to keep up to date. There is considerable interest attached to the growing of Zonal Pelargoniums, and few cultivators of plants care to be without them during the summer months. Many of the varieties are adapted for blooming in winter, though not with the same freedom as in summer; but to have them at their best during the dull months flowering must be restricted in summer, and a regular heat of 50° and a dry atmosphere accorded between December and March.

Plants which are procured now may be had in thumb pots, or obtained as rooted cuttings out of pots. In the latter case pot them when received in a light sandy mixture in the small pots referred to, placing them near the glass in a heated house. If moist soil is used in potting light sprinklings of tepid water may be used for a few days, and then afford a good watering. Rooting will proceed, and soon fill the pots with roots, when a shift may be given to the next size pot. The plants can have cooler treatment after they commence to root in the small pots.

Cuttings can be procured as well as rooted plants, or cuttings may be readily obtained, perhaps, from tall plants of good varieties. Vigorous, firm, short-jointed cuttings are the easiest to root. Their length may be 3 or 4 inches. Cut the base squarely below a joint, and remove the lowest leaves. Should the cuttings be soft and sappy, owing to better not being procurable, let the base dry an hour or two before insertion. When growing them for pot culture insert the cuttings singly in thumb pots, using turfy loam, leaf soil, and plenty of sand. Insert the cuttings firmly in the centre of the pots; several cuttings may also be placed round the edges of 3-inch pots. This is a much readier method, and with care in dividing at the time of potting little if any check is given. After inserting the cuttings water them in with a rosed can, and stand the pots on a warm, dry shelf in the full sun, applying no direct shade to prevent flagging, as is the case with the majority of cuttings. The lower leaves may flag, but the central parts usually remain fresh. As the soil dries on the surface sprinkle the cuttings lightly with the syringe. Heavy waterings are not needed, and may, if given, sour the soil and prevent rooting. When fairly well rooted transfer the plants to cooler and airier quarters, as it is essential they make a short-jointed steady growth.

On the pots becoming filled with roots move the single-rooted cuttings to 3½-inch pots, and in the case of several cuttings in one pot divide these singly, and put also in 2½ to 3½-inch pots. The compost may consist of turfy loam, one-fifth of decayed manure and sand, potting firmly. The situation best adapted for the plants at this stage is a shelf in the greenhouse. Water carefully at first, until the roots begin to work freely, when more water may be given, never allowing the soil to become dry.

The next potting should be to 5-inch pots, similar compost to that previously recommended being employed. Drain the pots well, and over the rough parts of the drainage, which may consist of moss, bits of turf, or riddings from the compost, sprinkle a dusting of soot. This will assist in preventing worms entering the compost. Frame treatment is best for them at this stage, standing the pots on a moist base. The frame can be kept closed for a few days to encourage fresh rooting, after which admit air freely and expose fully on every favourable occasion. In July, August, and part of September outdoor treatment may be given them entirely if intended for winter blooming, removing all flower stems until September. After the plants have been placed in 5-inch pots those not wanted for winter may be allowed to bloom as they will. During August liquid manure can be beneficially applied once or twice a week to well rooted plants intended for winter blooming. The points of the shoots nipped out several times during the early stages of growth will produce a bushy habit of plant.

A few good varieties among the singles are Rev. Dr. Morris, Brilliant, Stella Massey, Mr. W. Brown, Agnes, Swanley Single White, Henry Jacoby, Dr. McDonald, Herrick, Delicata, Lord Wolseley, Cassiope, Phyllis, Mrs. J. E. Taylor, Albion, Niagara. In the double class the following are excellent:—F. V. Raspail Improved, Madame Leon Dalloy, Magenta King, Gloire de France, Madame

Rosain, Swanley Double White, and Pearl. King of Denmark, also known as Beauté Poitevine, and Mdle. Trine, are good winter bloomers.

It is important that cuttings of bedding Pelargoniums in pots or boxes should now be transferred singly to pots, 4 inches diameter being a suitable size for strong cuttings, 3-inch size for those with a lesser quantity of roots. After potting place in a little heat and moisture to restart them into growth, but when once again making roots cooler positions must be found for them, eventually placing them in frames on a moist base. Afford due supplies of water and abundance of air on favourable occasions. Protect the glass at night when frosts prevail in late April or May. This treatment will gradually harden them to the open air.—E. D. S.

Tabernæmontanas.

TABERNÆMONTANA coronaria flore-pleno is a beautiful evergreen flowering shrub which at one time most deservedly occupied a very prominent position amongst stove plants. It does not, however, appear to be so much appreciated at the present time as its merits deserve. In habit and character it is very similar to the much-prized Gardenia. Its flowers, which are freely produced from the forks of the branches of from ten to twelve in a cluster, are pure white and fragrant. Having been very successful in the cultivation of this plant I will relate my experience, trusting it may be of interest to the readers of the Journal.

Cuttings of half-ripened wood may be inserted any time during the spring or summer, but I much prefer the spring. Two or three cuttings can be placed in a 60-size pot, afterwards plunging in a good bottom heat. When rooted the young plants must be removed from the frame and gradually inured to air, afterwards placing them singly in small pots. Use a compost of good lumpy loam and fibrous peat in equal proportions, one-third partly decayed leaf soil with a little dried cow manure, and a fair proportion of sharp silver sand. Before the roots become much restricted for room the plants should have liberal shifts as these are requisite, for on no account must they be allowed to become root-bound or they will quickly present a stunted appearance. The process of watering must be very judiciously performed till the roots have taken full possession of the soil, after which water may be applied with greater freedom. Where practicable I recommend a stock of young plants to be raised every two or three years, as by this method much better flowers are produced than it is possible to obtain from older plants.

Having so far dealt with the cultivation of young plants I will now make a few remarks in reference to old ones; for although, as before mentioned, the flowers are not so large as on younger plants, they are nevertheless produced in much greater numbers, thereby making them indispensable where a large supply has to be maintained. Plants that are too large for general requirements should be kept rather dry for two or three days after flowering, after which they may be pruned back to the old wood. No fear need be entertained in reference to over-pruning, as I know of no hardwooded plant that recovers itself after severe pruning more readily than the Tabernæmontana. The plants should be liberally syringed two or three times a day till the young growths appear, at which stage it will be necessary to repot them. Remove some of the old soil from the ball, afterwards placing the plants in the same sized pot as it was previously in, using a compost similar to that above recommended.

There are other kinds of Tabernæmontanas, one of the best being *T. cymosa flore-pleno*. This variety, it appears, was originally obtained from a Belgian garden, and by some growers is considered superior to the double *T. coronaria*. It is occasionally offered in trade catalogues as *T. camassa*, and is said to be more profuse in blooming than the first mentioned and more generally grown form.

Tabernæmontanas are subject at all stages of their growth to the attacks of various insect pests, mealy bug being especially troublesome. A sharp watch must, therefore, be kept, and upon their first appearance immediate steps should be taken to insure their removal, for if once this pest is allowed to become thoroughly established it will be found very difficult to eradicate. One of the best insecticides that I have tried for the removal of mealy bug is petroleum. This should be used in proportion of a wineglassful to 3 gallons of water, the whole being thoroughly mixed by filling the syringe two or three times, and returning its contents back into the can, repeating this operation at about every six or eight syringefuls. If this is performed, say, once a fortnight, and the plants syringed twice a day with clean water, it would do much towards preventing the attacks of insects, and at the same time be very beneficial to the growth of the plant.—G. P.

American Chrysanthemums.

IN the past many sterling varieties, both Japanese and incurved, have been sent to us by American raisers. For the last season or two, however, there has been a lull in that quarter. This year we are promised several additions to both sections by that enterprising raiser, Mr. Nathan Smith, of the Adrian Nurseries, Mich., U.S.A. No less than nine novelties are enumerated; they are described as pedigree varieties, the names of the parents being given in each instance. From photographs of the blooms and the raiser's descriptions I have an opportunity of forming a fair knowledge of the quality of each. As a rule varieties raised outside of England improve when subjected to the cultural methods practised here. For the benefit of English cultivators I will describe those I think likely to be of service to growers during the coming season.

Foremost amongst them is White Bonnaffon. As its name implies it belongs to the incurved section, and should prove a welcome addition just now when this type of flower is at rather a low ebb in England. The new comer is a cross between Mrs. H. Robinson and Mrs. H. McY. Twombly. In formation the florets are identical with Major Bonnaffon, while the colour is pure white. In habit of growth it is short-jointed, with large dark-green leaves; it is not more than 3 feet, though I suspect that under the cultural conditions practised at home it will assume a greater height. Orizaba is a Japanese incurved of a pleasing shade of light pink. When we consider that its parents were Mrs. E. G. Hill and Mrs. W. C. Egan, it will be granted that its form should be of the best. This, too, is dwarf in growth.

Amongst Japanese several varieties call for favourable comment. Foremost is Lavender Queen, its parents being Mrs. James Eadie and Thanksgiving. It is a full-sized Japanese with florets rather below medium width, filling up in the centre well, and making a bloom of great depth. The colour appears to be unique—a soft shade of lavender pink; under artificial light it shows to perfection. Goldmine is from H. L. Sunderbruck and Modesto, both desirable varieties well known to English cultivators. In colour it is a rich golden yellow. The florets are broad, slightly recurving at the edge; the tip curls and whorls. The centre is quite full, building up a large solid bloom that should prove advantageous to cultivators.

Monrovia superba and Nerota, from their appearance as photographs, do not appeal to my taste. The blooms appear to be built up with rather short, stiff florets, lacking grace, as we judge of it in our standard of excellence. Pluma belongs to the hairy section, and is delicate pink in colour. Judging from its appearance it should prove a desirable addition to the section.—E. MOLYNEUX.

The Royal Horticultural Society.

Scientific Committee, February 27th.

Present: Dr. M. T. Masters (in the chair); Mr. Michael, Mr. E. Im Thurn, Rev. W. Wilks, and Rev. G. Henslow, Hon. Sec.

The Lucombe Oak.—Specimens of foliage and acorns were received from Rev. J. H. Ward of Silvertown Rectory, Exeter, from a tree growing in the churchyard, requesting for information as to their identity. Dr. Masters has supplied the following details. "I believe the leaf and acorns exhibited to be those of the Lucombe Oak, or from one of its descendants. The Lucombe Oak was a hybrid between the Turkey Oak (*Q. Cerris*) and the Cork Oak (*Q. Suber*). The leaves are all but evergreen; indeed, in some of the varieties, quite so. As is the case generally with hybrids, the descendants from the first cross vary extremely, consequently there are many forms and varieties of the Lucombe Oak in existence. As the specimens came from Exeter there is additional ground for presuming it to be descended from the Lucombe, as the original tree was raised in the nursery of Lucombe, Pince and Co., of Exeter. The Fulham Oak, raised in the Fulham Nurseries, had a similar origin, and now I believe it to be impossible to distinguish its descendants from those of the Lucombe Oak. A full account of these Oaks will be found in Loudon's "Arboretum," vol. iii.

Large Yew Tree.—Mr. Ward also mentions the fact of a Yew tree in the same churchyard being 25 feet in circumference at a height of 4 feet from the ground, and asks if it is a reasonable conjecture that the tree was planted before the Norman Conquest.

Data as to the rate of growth of Yew trees have been supplied from trees planted in Basildon churchyard in 1726. They have been measured in 1780, 1796, 1834, and 1889. They were found, after

a commencing period of more rapid growth, to be pretty regularly increased by one line (one-twelfth of an inch) per annum. (See "Nature," October 17th, 1889).

Bulbiferous Scilla.—A plant of *Scilla nutans* was received from Mr. Alex. Mortimer, 1, Paper Buildings, Temple, in which the outer bulb scale had become greatly elongated upwards, forming a closed tube. It bore two small bulbs on the inner surface, and was greatly thickened at the summit, as if attempting to form a larger bulb; but no other than the above two were developed. They both possessed small rolled-up green leaves.

Orange malformed.—Dr. Masters showed an Orange having a band of paler and smoother rind than the rest of the skin. It was referred to Dr. Bonavia for examination, who writes as follows:—"It somewhat resembles the Bigaradier tricolor Orange, which has a yellow skin, with orange stripes when ripe. Again, the Bigaradier bizarrerie has smooth parts of an orange colour, and warty parts yellow. These parti-coloured Oranges are normal." Dr. Bonavia would theoretically explain this peculiarity by referring to the "fingered" Orange, which he regards as a whorl of modified leaves, coalescing to form a covering to the inner portion of the fruit. To apply this theory to the case in question, he would compare the paler portion to, say, a *Euonymus*, which may have green leaves with an occasional yellow one, or again he would compare it with striped petals, as of the York and Lancaster Rose. The objection to Dr. Bonavia's ingenious theory lies in the fact that the paler coloured stripe did not correspond with a single carpel but covered the half of one and the half of the adjacent carpel, so it would represent two halves of different capillary leaves. Secondly, striped flowers are probably the result of crossing two whole-coloured flowers. This is obviously the case with *Petunias*, a purple and white flowered species having been the parents of all our garden forms. So that it would seem more probable that the Orange had received the pollen of a smoothskinned variety, and the tubes penetrating one placenta, common to two adjacent carpels, had influenced the surface on both sides of the division. Similar stripes have been known to occur on the fruit of one variety of *Theobroma* (Cocoa) when pollinated by a second variety. Dr. Bonavia's report will appear in full in the Journal of the Royal Horticultural Society.

Drill Hall, March 13th.

THE exhibition in the Drill Hall on Tuesday was a most attractive one, both in the quality of the products shown and their diversity. Seldom has the hall been better occupied, and rarely has a better display of early flowers been seen.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); Rev. W. Wilks, and Messrs. R. Parker, E. Beckett, E. Shaw Blaker, J. Cheal, M. Gleeson, J. H. Veitch, A. H. Pearson, W. Pope, A. Dean, S. Mortimer, A. F. Barron, J. W. Bates, H. Markham, C. Herrin, G. Wythes, G. Kelf, F. Q. Lane, G. Reynolds, W. J. Empson, J. Smith, G. Norman, J. Willard, G. Bunyard, and W. Poupard.

Mr. R. Parker, gardener to the Duke of Richmond and Gordon, sent baskets of Goodwood Pippin Apple in fine condition; also Wellington, and two other varieties with local names. The King's Acre Nurseries, Ltd., Hereford, also sent a dish of King's Acre Pippin, which was staged in sound condition. Mr. C. Ross, gardener to Capt. Carstairs, Welford Park, Newbury, sent a good dish of White Nonpareil. A few other dishes were also staged by exhibitors, but failed to secure recognition from the committee. Radishes were staged in three varieties by Mr. J. Crook, Forde Abbey, Chard. They were well grown and of good flavour.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. C. T. Druery, H. B. May, R. Dean, G. Reuthe, J. H. Fitt, W. Howe, J. Hudson, J. Jennings, J. F. McLeod, R. Fife, C. J. Salter, W. H. Lees, J. Fraser, G. Gordon, C. Jefferies, J. Walker, W. Bain, J. D. Pawle, E. H. Jenkins, H. S. Leonard, C. E. Shea, W. J. James, H. J. Jones, H. J. Cutbush, C. Blick, G. Paul, J. W. Barr, T. W. Sanders, and E. Mawley.

Messrs. J. Peed & Sons, Roupell Park Nurseries, Norwood, arranged a pleasing display of flowering and foliage plants; the former were arranged in baskets, while the latter formed a good background and edging to the exhibit. The flowers were *Genista fragrans*, *Begonias*, *Ericas*, *Cinerarias*, *Mignonette*, *Cyclamens*, and *Hyacinths*. These, with the Palms and Ferns, were attractive. Ferns were well represented by Messrs. J. Hill & Son, Barrowfield Nurseries, Lower Edmonton, who staged a great variety of specimens, also baskets containing species and varieties with tinted and variegated foliage, which included *Doodia aspera multifida*, beautifully coloured; *Athyrium Goringianum pictum*, and *Adiantum scutum roseum*, *Farleyense*, and *Collisi*, also *Blechnum latifolium*. The specimens were grown in Messrs. Hill's well-known style (silver Banksian medal).

Messrs. W. Paul & Son, Waltham Cross, arranged a large exhibit of hardy flowering shrubs, which was much admired, and attracted great attention. The *Camellia* and *Carnation* flowered Peaches were delightful at this period, as were plants of *Prunus triloba* in splendid condition. The double white Peach and *P. sanguinea flore-pleno* were also attractive, while plants of *Staphylea colchica*, *Forsythia suspensa*, and *Clematis indivisa lobata* all contributed to make a welcome addition to the display (silver-gilt Banksian medal).

A fine group of *Clematises* was arranged by Mr. H. B. May, Upper Edmonton, all tastefully displayed with Ferns, Palms, and Bamboos,

while a few plants of Spinners and Gloire de Lorraine Begonias added a special feature. The Clematises were grown in 5-inch pots, and were laden with flowers. The most prominent were Lord Wolsoley, Mrs. Quilter, Miss Bateman, and Lady Lonsborough.

Messrs. Barr & Sons, Covent Garden, opened the Narcissus season with a pretty display. The chief forms were coronatus, Victoria, telamonius plenus, Golden Spur, Henry Irving, ornatus, spinus, Horsefieldi, and Sir Watkin; also hardy Cyclamens in variety, Crocuses in various forms, and Chionodoxas, Lachenalias, and Irises. A pretty display for the season.

Messrs. J. Laing & Sons, Forest Hill, again staged a fine table of foliage and flowering plants, chiefly of the decorative type. The most attractive subjects were Azaleas in variety, Epacrises, Calla Elliotiana, and Clivias. The foliage plants, however, formed a good feature, and included well grown plants of Crotons, Dracaenas, Palms, and Ferns. Messrs. Paul & Son, Cheshunt, staged an interesting display of alpine and rock plants, with Hellebores and a few spring flowering plants. The Hellebores were represented by *H. colchicus coccineus*, *H. c. punctatus*, *H. orientalis*, and *H. o. Gretchen Heineman*. The Saxifragas also formed a pleasing feature (bronze Banksian medal).

FIG. 63.—LÆLIA JONGHEANA.

A large table of Azalea mollis seedlings was staged in good condition by Mr. J. Russell, Richmond. The plants were shown in a variety of colours, and had evidently been well developed (silver Banksian medal). Messrs. J. James & Son, Farnham Royal, Slough, have been noted as specialists in the cultivation of the Cineraria, but it is doubtful if they have ever staged so perfect a strain as seen on this occasion. The plants left little to be desired as far as habit is concerned, while the flowers, both in form and colour, testify to the skill and care that has been expended in building up this noted strain (silver-gilt Banksian medal). Messrs. Sutton & Sons, Reading, arranged a table of Cinerarias in two varieties, Sutton's Light Blue, a variety of dwarf habit and pleasing colour, and Sutton's New Pink, a pink.

A table of fine Azalea mollis was contributed by Messrs. R. & G. Cuthbert, Southgate. The plants were dense masses of flowers in their well-known delicate tints, with a groundwork of Ferns (silver Banksian medal). Mr. Geo. Mount again sent up some glorious Roses, comprising boxes of Captain Hayward and Catherine Mermet, with Mrs. J. Laing and Captain Hayward on long stems, all in first-rate form, with good foliage (silver Banksian medal). Some well grown Cyclamens were staged by the Church Road Nursery Co., Hanwell.

Messrs. Wm. Cutbush & Son, Highgate, presented a large table of Ericas in variety, some well flowered Epacrises, Begonia Gloire de Lorraine, Ericas, Acacias, and Boronias, while the hardy plants were Pyrus malus floribunda, Staphylea colchica, Laurus, and double flowering Peaches, the whole arranged with Palms, Azaleas, and a front of Ficus repens. A small group of plants was staged by Messrs. R. Wallace & Co., Colchester, comprising a basket of Anemone blanda and Ranunculus ciliatus.

Messrs. Jas. Veitch & Sons, Ltd., Chelsea, staged a table of Primulas, which included *P. stellata* and *P. rosea*. Mrs. Makins (a floriferous white), Gigantic Rose, and Gigantic Blue in the ordinary fringed types were good, as were also the double forms, Double Salmon, an effective colour; Double Crimson, a bright colour; and Double Mauve. The same firm also exhibited a small group of Cerasus pseudo-Cerasus Watereri in excellent condition. The plants were full of flower, and the delicate blush of the petals made them quite noticeable. Mr. H. J. Jones, Rycroft Nursery, Lewisham, staged a table of spring flowers, consisting of Hyacinths and Narcissi. The former were represented by a large number of varieties, while the latter contained well developed bunches of Mrs. Thomson, Horsefieldi, Henry Irving, Sir Watkin, ornatus, and obvallaris (silver Banksian medal).

ORCHID COMMITTEE.—Present: J. G. Fowler, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshaw, H. Ballantine, N. C. Cookson, H. Little, J. T. Gabriel, H. J. Chapman, J. W. Potter, F. Sander, E. Hill, W. H. White, H. T. Pitt, H. Tracy, W. H. Young, F. J. Thorne, and J. Douglas.

Mr. H. Whiffen, gardener to J. Bradshaw, Esq., The Grange, Southgate, arranged a small group of Orchids. There were several forms of Cattleya Trianae, including the chastely beautiful *C. T. Amesiana* and *C. T. amana*, with *Coelogyne cristata alba*, *Laelia harpophylla*, and a few *Odontoglossums* (silver Banksian medal). Messrs. H. Low and Co., Bush Hill Park, exhibited a small group in which *Dendrobium Wardianum* Lowi, a splendid plant of *D. Brymerianum*, *D. Fitchianum*, *D. Madonna*, *D. Ainsworthi intertextum*, *D. Dowianum*, *D. nobile* Murrhinianum, *Colax jugosus*, and a few others were conspicuous. Mr. J. M. Black, gardener to R. G. Thwaites, Esq., Streatham, sent several Orchids, including *Dendrobiums* and *Odontoglossums*.

Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, showed a collection of *Dendrobiums*, including several superb varieties. The plants were excellently grown and carried flowers of exceptional size and substance. The varieties comprised principally forms of *splendidissimum* and *Ainsworthi*, with many others (silver Flora medal). Messrs. J. Cypher & Co., Cheltenham, staged a small collection mainly of *Odontoglossums*. There were several well-known varieties as well as one or two seedlings. Mr. W. J. Empson, gardener to A. H. Wingfield, Esq., Amptill, exhibited a few *Cypripediums*.

The smaller exhibits of Orchids were very numerous, and included specimens from Messrs. W. H. White, W. Murray, H. J. Chapman, H. A. Tracey, H. Low & Co., H. Whiffen, R. Roberts, H. Garnet, F. Sander & Co., and J. Veitch & Sons.

Certificates and Awards of Merit.

Dendrobium Burberryanum (W. H. White).—This is a hybrid that resulted from a cross between *D. Findleyanum* and *D. Dominicanum*. It is a lovely form. The sepals and petals are rich red, as is the front lobe of the lip. The central portion is cream, and the side lobes of the throat reddish crimson (award of merit).

Laelia Jongheana (Messrs. F. W. Thurgood, F. J. Thorne, and F. Sander & Co.).—This is an Orchid that was shown by the above exhibitors with slight variations of form and colour. The sepals and petals are flat, and of a rose purple, the lip being white with a heavily limbriated rose lip and a yellow throat (award of merit). See illustration fig. 63.

Odontoglossum crispum, *Oakfield Sunrise* (R. Roberts).—The sepals are white, suffused with cream and one or two pin head spots of chocolate. The sepals except the white tips are chocolate crimson (award of merit).

Odontoglossum elegans, *Eastwood Park variety* (H. Ballantino).—A most attractive Orchid. The sepals and petals are delicate rose, with both large and small brown spots (first-class certificate).

Pentapterygium serpens (J. Downes).—An uncommon Himalayan plant with bright red tubular flowers hanging beneath the growths (award of merit).

The Evolution of Plants.

The attendance at the afternoon meeting in the Drill Hall, when Mr. R. Irwin Lynch, the distinguished curator of the Cambridge Botanical Garden, read a paper on this subject, was not nearly so large as might have been expected considering the interest and importance of the topic. There were large numbers of persons in the body of the hall, and it speaks well for the enthusiasm of various gentlemen that the society continues able to provide these papers, for there was on this, as on other occasions, a continuous buzz that was annoying to the audience at the lecture and must have been very disconcerting to the lecturer. As we have said before we wish something could be done to mitigate this trouble.

The field covered by the title of Mr. Lynch's discourse is a tremendously wide one, which becomes more and more interesting the deeper it is penetrated. Considering the experience of the essayist it need scarcely be said that the subject was treated of in a most entertaining manner, while at the same time the essayist succeeded in maintaining its instructive aspect. Notwithstanding the strain that Mr. Lynch was undergoing the noise prevented those at the back from hearing much that was said. The complete text will, however, be given in the Journal of Royal Horticultural Society, and will be eagerly read by many persons.

Hardy Fruit Garden.

Grafting Fruit Trees.—Healthy and vigorous fruit trees that grow well and produce good wood and foliage but do not bear fruit, may be changed in character by grafting upon them scions of superior varieties. The trees which are to be operated on require the branches to be headed down to near the point selected for inserting the scions. This heading down is best carried out several weeks prior to grafting, but a fresh slice ought always to be removed on the day of inserting the scions, because then the edges of the bark work freely and the grafts are more readily fixed.

Scions must be in a dormant condition when inserted, and to insure maintaining them quiescent from the time they are cut from the trees to preparing them for insertion, they must be laid in moist soil nearly their full length under a north wall.

Proper Time for Grafting.—The exact time for inserting grafts is just when growth commences on trees in general. Of course, trees headed down completely to bare wood have no buds to show when growth commences, but neighbouring trees indicate this; therefore, noting them, it is safe to assume that the sap is beginning to be active in the headed down trees. From the middle to the end of March is usually the best time; in late seasons early April.

Crown or Ring Grafting.—This is the best form of grafting for large branches and all stocks over an inch in diameter. Several scions or grafts may be attached to one stock, allowing a couple of inches between each. Slit the bark down the side about 2 inches, passing just through the bark. Select the middle part of the previous year's shoots to form the scions, each containing four buds. Cut these the same length as the slit in the stock, the cut being made in a slanting direction downwards. At the upper edge of the cut make a short transverse incision, which will form a shoulder by which the scion can be firmly seated on the stock. Lift the bark on each side of the slit in the stock, and pass the scion firmly, but gently, down until the proper position is reached. It is important that the inner barks of both stock and scion should exactly join in order that a good union may be formed. When a convenient number of scions have been attached to each branch secure them all in at once with some soft tying material, and cover the whole with grafting wax. Maintain moisture by damp moss secured round.

Side or Whip Grafting.—Young stocks less than an inch in diameter may be grafted simply by this method, working quite low down. In this case the scion ought to be the same thickness as the stock. The top of the stock should be a slanting cut, made upwards, 3 inches long. The cut in the scion must be downwards the same length, and made to fit as exactly as possible. Choose good ripe wood with bold buds as scions, though the buds ought to be quite dormant. When the grafts are secured, tied in, and waxed, soil can be heaped round. This will further tend to keep all regularly moist.

Completion of Pruning.—Standard fruit trees, bushes and wall trees, which have not hitherto been pruned or regulated this season, must be attended to at once. Nothing is better for standard trees than the practice of thinning-out branches wherever they are crowded, especially removing those crossing and interlacing, not shortening them as a makeshift, but cutting them out entirely close to the main branches from which they spring. Bush trees should have the main branches reduced in number if it is apparent that too many exist for the welfare of the trees. No varieties of Apples and Pears ought to have the main branches closer together than a foot, and some of the more vigorous growers, having spurs longer than normal, will be all the more prolific at 15 to 18 inches asunder; also reduce the length of spurs, and thin-out where unduly crowded.

Now that Gooseberries are fairly advanced in growth, a little pruning away of shoots which may have been denuded of buds will be advantageous, giving the bushes all the mere chance for accommodating the fruitful shoots. Newly planted Gooseberries and Currants may have the shoots shortened two-thirds, so that the resulting growth will be strong and vigorous for establishing a shapely tree or bush.

Raspberries may also be shortened, established canes having the tips removed to the tops of the stakes or trellis, and young newly planted canes cut closely down near the soil.

Attend also to wall trees. Horizontal and fan-trained may have every other branch taken out, or such as will admit of those remaining having sufficient space, and being well placed for the fruiting spurs to receive more light and air. Vacancies caused by the removal of dead wood or worn-out branches may possibly be filled up with young shoots from the base or other parts. It is necessary to obtain them from as near the base as possible, thus maintaining a well balanced and furnished tree. In the case of Morollo Cherries on walls secure a fair quantity of young wood, nailing it in about 4 inches apart, leaving it, as a rule, unshortened. Cut out old and weak wood.

Fruit Forcing.

Peaches and Nectarines.—*Early Forced Trees.*—During the stoning process an equable temperature is desirable. Too much heat at night deprives the trees of rest, and this is not favourable to the fruit. Cold draughts in the daytime sometimes give a sudden check fatal to the crop. Attend to thinning the fruit betimes. Secure all shoots required for extension to the trellis as they progress, stopping successional growths at a length of about 15 inches, and pinch laterals at the first leaf, also succeeding growths as made. Shoots retained to attract the sap to the fruit stopped to one leaf, they having previously had the first growth pinched at the second or third leaf. Avoid stimulating the trees whilst stoning, but afford due supplies of water and food of a phosphatic rather than nitrogenous nature.

Second Early Forced Trees.—Proceed with disbudding, a shoot being left at the base of the present year's bearing wood, and one level with or beyond the fruit. The first must be trained forward, but the latter should be stopped at the second or third joint. Upon extensions leave young shoots at 15 to 18 inches distance, the growth from the extremity being trained as a continuation of the primary branch. Commence tying early, as when the shoots are allowed to grow considerably they cannot be brought down without danger of breaking. Guard against overcrowding, as it is fatal to fine, highly coloured fruits and the formation and perfection of the wood for future crops. Thin the fruits by degrees, leaving these well disposed upon the upper side of the trellis.

Houses Started at the Beginning of February.—Any trees still in blossom should be fertilised when the pollen is ripe. When the fruit is all set recourse must be had to syringing in the morning and afternoon of fine days, but an occasional sprinkling, with damping the house, will suffice in dull weather, always having the foliage and young fruit dry before night. Disbudding must be done gradually, commencing with the most forward growths, also thinning the fruit after it is seen which takes the lead in swelling. A temperature of 55° at night, 5° less on cold mornings, 55° to 60° by day, advancing to 65° or 70° with gleams of sun, will bring the fruit on sufficiently fast, ventilating from 55° to 60°, and not allowing an advance above 65° without full ventilation.

Houses Started Early in March.—With the flowers expanding syringing the trees must cease, for there is danger, especially in dull weather, of weakening the blossom and converting the pollen into paste. An occasional syringing may, however, be practised if the weather be unusually bright and the atmosphere dry. Damping the floors and borders is generally sufficient and a safer plan. Admit air freely in mild weather and fertilise the flowers on fine days. Maintain the night temperature at 45° to 50°, 55° by day and 65° from sun heat. Admit a little air constantly, increase the ventilation at 50°, and give more as the heat rises, having full air on at 65°, closing at 50°. Superfluous flowers on the under side or back of the shoots may be removed.

Late Houses.—Where the roof-lights have been removed they should be replaced, the buds being well advanced in swelling, and promise an abundant crop of fruit. If there are any traces of aphides apply an insecticide or fumigate the house before the flowers expand. Nothing conduces more to a good set than removing the flowers on the under side or back of the trellis, and turning on the heat after the anthers show for a short time in the early part of the day, to advance the temperature to 50° and to permit of ventilation, as if there is a prevalence of dull, cold weather at that time, closing the ventilator for protection prejudices the pollen. Houses that have fixed roof-lights must have the borders rendered thoroughly moist, but not made sodden and sour.

Pines.—*Suckers.*—The rooting of potted suckers will be indicated by the growth of the foliage, but it is well to turn the plants out of the pots, or a portion of them, to ascertain the condition of the roots and the soil. The young roots which issue from the base of suckers or plants similarly treated are very tender and susceptible of injury from the effects of too much bottom heat, hence when the roots reach the sides of the pots 85° is ample, above which there is danger. When the bottom heat is excessive the pots must be raised, placing some loose tan under and around them to allow the superfluous heat to pass away without injuring the roots. The plants should be carefully supplied with water and not have too much top heat; nor be too far from the glass, or they will become drawn and weakly.

Potting.—Once the suckers and other plants subjected to similar treatment start they make roots rapidly, therefore have soil ready for transferring to the fruiting pots, as it is important that they be grown without check, by being either root-bound or dry. Sound, fibrous loam in good sized lumps is the best material for potting, rejecting the dusty particles. It should be pressed firmly round the balls of the plants, watering them if the soil be dry (not otherwise) with tepid water, and plunging them in a bottom heat of 90° to 95° until the roots have possession of the fresh soil, when 85° is more suitable. The top heat should be at 60° to 65° at night, and 70° to 75° by day, with 10° to 15° rise from sun heat.

Fruiting Plants.—Those at or near the flowering stage should have a night temperature of 65° to 70°, and 75° by day, with 80° to 90° from sun heat, closing at 85°, well damping paths and walls at the same time. Successional plants may have a bottom heat of about 85°, ventilating at 80° and closing at 85°, lightly sprinkling the plants occasionally.

A genial atmosphere; should be secured by damping the floors and pit walls as they become dry, but it is not good practice to syringe the bed between the plants. Examine the plants once a week and supply tepid water containing a little stimulating substance, such as guano or soot, when required.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Tabernaemontanas (*F. G. B., Lincs.*).—The thoroughly practical article by "G. P.", on page 230, will no doubt give you all the information you require respecting these plants. If, however, you wish further information on this or any subject and will write, we shall be pleased to assist you.

Sowing Gypsophila elegans (*Gyp.*).—Seed of this hardy annual, which has feathery white and pink flowers, may be sown outdoors about the middle of April. Choose light fertile soil in an open position, working it well, and make it fine on the surface. Sow the seed on this bed, and just cover with a sprinkling of fine potting soil. When the seedlings attain to the height of an inch gradually thin them out to 6 inches apart, and maintain the soil about them clean and loose on the surface.

Eucharis Infested with Mite (*C. A.*).—The bulbs are infested with mite, which accounts for the unsatisfactory state of the plants. It is generally advisable, when the plants become infested with this pest, to turn them out and cleanse the bulbs by means of some approved insecticide, there being few better than hot water, as hot as it can be borne by the hand for a minute (about 145°), letting the bulbs remain in at that time, rinsing or moving up and down so as to get the water into the scales or outer coating of the bulbs. They can then be potted in soil which has been scalded previously, so as to allow for draining and getting into good condition for potting. The plants should have bottom heat so as to accelerate root action, and get them quickly re-established. This answers for a time, but in mite districts it seems to get on the plants again, when occasional applications of Clibran's Eucharis mite killer will keep it down, carefully following the instructions. You may use soluble phenyle, one part to ninety-six parts soft water, or 1 gill ($\frac{1}{4}$ pint) to 3 gallons of water. Both may make the plants rather queer for a short time, but they recover, the substances then acting as manure.

Ivy-leaved Pelargoniums (*M. S.*).—Defective root action, caused either by over-watering, over-dryness, or a too great fall in the temperature at some time, has led to the injury to the shoot enclosed. Perhaps the best plan to adopt now would be to let the soil get nearly dry, then cut back the shoots below all the diseased parts, and after fresh growths push remove half of the old soil or more, and place fresh compost round the roots. A mixture of five parts loam, one of dried manure crumbled into small particles, one of leaf mould, and one composed of equal parts of wood ashes (or crushed charcoal) and sand, will form a suitable compost.

Vine Leaves Yellow Spotted (*G. G. B.*).—The leaves show no traces of parasites. Their appearance is probably due to a deficiency of chlorophyll resulting from the recent dull and cold weather. This almost precluded ventilation, and in consequence there has been a slight defect of tissue formation and consequent thinness of foliage, which has been acted upon somewhat injuriously by a recurrence of brighter weather and drier atmosphere. We can only advise very careful ventilation, commencing early, and so admitting it as not to induce sudden drying, maintaining, however, some evaporation, so as to secure foliage of stouter texture. It would also be advisable to allow as much lateral extension as consistent with the full exposure of the foliage to light and air, always avoiding overcrowding or interfering with the access of light to the principal leaves. The fertiliser you name ought to have improved the colour of the foliage, and a top-dressing of the undermentioned mixture will be followed by beneficial results:—Dissolved bones, dry and crumbling, 3 parts; powdered saltpetre, 2 parts; sulphate of magnesia, 1 part, mixed, using 3 or 4 ozs. per square yard. A light mulching of sweetened horse droppings would also increase the root action, and likewise the foliage, improving its colour by the ammonia. This, however, must not be excessive, or it will injure the foliage and tender growths.

Plants for Beds (*Ladysmith*).—The plan is a very difficult one for effective bedding, a bed with a design inside being far superior to a chopped arrangement. Summer bedding:—No. 5, 6, 9, 10, Arundo Donax variegata, one plant each centre; Fuchsia Coral Bedder (Lyes'), 2 feet apart; Viola Snowflake, white, or Viola A. J. Rowberry, yellow, as may be preferred for a groundwork. No. 2, 3, 13, 15, Chlorophytum (Anthericum) elatum variegatum, dotted 2 feet apart; Ageratum Swanley Blue or Lobelia Emperor William, groundwork. No. 1, 7, 12, Koniga maritima for white groundwork, dotted with Begonia semperflorens Zulu. No. 4, 8, 11, 14, Heliotropium Miss Nightingale, blue, dotted with Veronica Andersoni. No. 16, 18, Pelargonium Ivyleaf Madame Crousse, pink, dotted with Centaurea candidissima. No. 17, Begonias tuberosa, orange or bronze. No. 19, Roses in variety. No. 20, Carnations, Picotees, and Pinks. No. 21, Lilliums, Irises, Paeonies, Phloxes, Delphiniums. No. 22, Tritonia (Montbretia), Tigridia, Gladiolus, and Calochortus vars. Spring bedding:—No. 5, 6, 9, 10, Wallflower Belvoir Castle, yellow; Tulip Vermilion Brilliant. No. 2, 3, 13, 15, Wallflower Ruby Gem, Tulip Ophir d'Or, yellow. No. 4, 8, 11, 14, Wallflower Blood-red, Tulip Keisers Kroon, yellow and scarlet. No. 16, 18, Myosotis dissitiflora, blue; Tulip La Candeur, white. No. 1, 7, 12, Bellis Snowflake, double white; Bellis Rob Roy, double red. No. 17, Tulip Roi Pepin, rosy carmine striped white. No. 19, Narcissus in variety, Hyacinths in variety, Violas, Stocks East Lothian or Brompton. No. 20, Scilla sibirica and var. alba, S. bifolia and var. alba, Muscari botryoides and var. alba, Chionodoxa Lucilæ and var. alba, C. Tmolnsi, blue; Crocus in variety. No. 21, Hepatica in variety, Fritillaria in variety, Primroses and Polyanthus in variety. No. 22, Galanthus, Eranthis, Auricula, Alpine vars. Ranunculus, Turban in variety.

Names of Fruits.—*Notice*.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. The practice of pinning numbers to the eyes of the fruits tends to destroy one of the most characteristic features and increases the difficulty of identification. When Plums are sent to be named young wood of the trees should accompany them. Leaves of the trees are necessary with Peaches and Nectarines, with information as to whether the flowers are large or small. (*J. L. W.*).—Schoolmaster. (*T. P.*).—1, Court of Wick; 2, Cox's Orange Pippin; 3, Blenheim Pippin; 4, Bramley's Seedling; 5, Wellington; 6, unknown and worthless. (*A. S.*).—1, Lord Derby; Beauty of Stoke; 3, Tower of Glamis; 4, Nouvelle Fulvie; 5, Josephine de Malines; 6, Bergamotte Espereu.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*F. H.*).—1, *Cornus mas*; 2 and 3, seedling forms of *Cupressus Lawsoniana*; 4, *Thuopsis dolabrata*. (*W. P.*).—1, *Acacia longifolia*; 2, *A. ovata*; 3, *Fuchsia procumbens*; 4, *Statice profusa*; 5, *Anthericum variegatum*; 6, *Franseria latifolia*. (*G. A. F.*).—1, *Cattleya Trianae*; 2, *Coelogyne cristata*; 3, *Cypripedium Spicerianum*. (*E. B.*).—1, *Berberis Darwini*; 2, *Daphne Mezereum*; 3, *Crataegus pyracantha*.

Agricultural Demonstrations at Calne.

WE have been favoured with the report of trials by the Wiltshire County Council during the past year. The experiments were conducted in connection with the growth of rotation crops, grass, Clover, and Potatoes.

There were two trial stations, one at Quemerford being on strong clay, the other at Lickhill being on lighter soil, but we have no evidence to show that it is really what is called light land. The rotation crops were such as are generally associated with heavy land, and have no relation to the four-course system; they were Mangolds, Barley, Beans, and Oats.

The experiments had for their principal objects—

- (1.) The proof that really good rotation crops can be grown without the aid of farmyard manure for many years provided that artificials be judiciously employed, and
- (2.) The determination of the quantities of the latter which it may be most economical to apply on a stiff clay soil.

The conclusions arrived at by the committee as expressed in the report are as follows:—

“(1.) That it is quite possible to grow on land such as that at Quemerford good paying rotation crops of Mangolds, Barley, Beans, and Oats for many years in succession, with the aid of artificials, assisted by farmyard manure, all the produce being sold off the land.

“(2.) That manures suitable for the purpose are for Mangolds, nitrate of soda $4\frac{1}{2}$ cwt., salt 3 cwt., and superphosphate 1 cwt. per acre; for Barley, nitrate of soda $1\frac{1}{2}$ cwt., and superphosphate 3 cwt. per acre.

“(3.) That Mangold was most responsive to the action of artificials, and Beans least so.”

We imagine that most people who have been making a study of the results of farm trials which have been conducted during the last half-century have come to the conclusion that a fairly heavy or even strong soil is necessary for success in the continuous growth of cereals. Practical farmers would also be fairly unanimous in preferring a farm inclined to the strong rather than the light side, for the manures, especially the nitrogenous ones, take a much longer time to wash through a strong than through a light soil.

Whether, however, the committee is right in coming to the conclusion that the crops they are growing in small plots are really paying ones may be open to question. When the prophet explains the source of his inspiration there are generally a few unbelievers to be found who scoff at him and his faith. So when we find the Barley crop from strong clay land valued at 45s. per quarter, and Barley straw at £2 per ton to go off the farm, we are inclined to wish that we farmed strong land in a district where maltsters and straw dealers were in such a benevolent humour. Our experience is that Barley is worth only 28s. per quarter from some of the finest Barley land in the country, and that Barley straw may be easily bought at 25s. per ton.

We quite agree with the committee that the use of artificials on strong land should pay, but we would not go so far as to say that artificials will make poor strong land profitable. They may make the contra balance a smaller one, and in some cases even show a small profit; but the hard and stubborn fact is that agricultural prices are too low, and that there is not sufficient encouragement to farmers to speculate by sinking money in expensive manures when the prospect of a profitable return is so extremely uncertain.

One striking feature of these trials is the strong way in which they corroborate the results of the Woburn and Rothamsted experiments. Great stress is laid in the report on the prejudice which is so prevalent against the use of nitrate of soda, this, no doubt, arising from observation of its effects when repeatedly used alone or in excessive quantity, but no danger of exhaustion of the soil need be apprehended as the result of moderate annual dressings if used in conjunction with other suitable artificials, or with fair dressings of farmyard manure.

That Beans did not respond to the use of artificial manures in 1899 is not surprising; the only manure used was basic slag, and the land was probably too dry for the plant to make use of the manure applied. In previous years nitrate of soda and kainit had been tried on Beans with equally futile result, which shows that there were sufficient inexhaustible supplies of phosphoric acid and potash in the soil to produce a crop of Beans without eleventh-hour assistance.

We are somewhat of opinion that, given a good seedbed and a sufficiently full plant to face the summer with, strong land must be very poor indeed if it will not grow a crop of Beans. A great point is the hoeing; they must be kept clean until they are in flower, for the flowers will not set well if the roots are meeting with much competition from weeds.

The effects of artificials were tried on very poor and coarse grass which has sprung up on a plot of land which has gone out of cultivation. Nitrate of soda 2 cwt. and kainit 3 cwt. were tried separately and together; the points noted were, the coarseness of the growth promoted by nitrate alone, the greater vigour of the Clover resulting from the action of the kainit, and the very even and satisfactory nature of the growth where both were used.

The experiments in the growth of Potatoes clearly show the great value of nitrogen for this crop, even in addition to that contained in a good dressing of stable manure. They also show that a moderate dressing of farmyard manure, aided by a mixture of the three artificials, is the most profitable mode of manuring, but this year the omission of kainit was the most and of superphosphate the least felt of the three artificials. During the previous four years, however, 8 tons of manure aided by $4\frac{1}{4}$ cwt. of nitrate of soda had beaten any other manure or mixture of manures.

Potatoes have been grown both on the strong land at Quemerford and on the lighter soil at Lickhill, and we quote two extracts from the report which, we think, speak for themselves.

QUEMERFORD.—“Good crops of Potatoes may be grown here at a profit for four years (probably more) on the same land with artificials alone as a manure provided these contain nitrogen, phosphorus, and potash in suitable form and proportion.”

LICKHILL.—“It would appear that on this ground Potatoes cannot be very profitably grown for several years in succession with the aid of artificials alone.” *Verbum sap.*

Both as Quemerford and Lickhill experiments have been conducted in the use of nitragin. The bacteria of which nitragin consists are obtained in the first place from the nodules of leguminous plants and then increased by cultivation. Twenty-two kinds of nitragin are to be obtained, one for each variety of leguminous plant, and it may be applied either to the seed or to the soil. The better results have been obtained by treating the seed. “Taking the average results for the three years at both stations, a considerable gain has resulted from the employment of nitragin.”

Work on the Home Farm.

At last the weather has taken a turn for the better, and there is a prospect of again getting to work on the land. Spring-tooth cultivators will be more in demand than ever, for there will not be much time now for ploughing. The sowing of the spring corn in a decent seedbed is now the chief anxiety. Some of the Turnip land is so sodden with water that a good mould can hardly be got without ploughing a second time; but if it could be broken up with the drag and harrows at once and left to dry through, one good subsequent rain would make a thorough job of it. Perhaps we shall not get rain when we want it after having had too much.

A farmer tells us that his horses have practically done nothing for

two months, and if the conditions had been more favourable he would have had difficulty in finding men to work them.

Potatoes might soon be planted on land that is already ridged up as soon as the ridges are dry enough to split freely. At any rate, the manure might be got on and shaken out, the planting can then be quickly performed. Potatoes may be put in now on any kind of soil, and there is nothing saved by waiting after the middle of March. Had the last two months been ordinarily dry a large proportion of crop would already have been planted in the typical Potato districts.

An ordinary single-mould-board plough is the best for splitting the ridges, especially if there be a suspicion of wet in them, as it leaves the land lighter than a double-mould-board plough with its more pushing action. The common plough must take three-fourths of the ridge and turn it bodily into the furrow.

Clover seeds must now be purchased and be ready on the premises for sowing with the Barley. Prices of small seeds are decidedly higher than last year, especially Alsike and Cowgrass. Personally, we are not fond of either of these kinds, and shall be quite satisfied with white and red Clover. Good white is 9s. 6d. per stone and red 8s. 6d. Trefoil, too, is dearer; this is useful on dry soils, as it stands drought well, and it is said to be a good preparation for the corn crop following; but experienced flockmasters do not consider it a healthy food for lambs after weaning.

Of one thing we are certain, the best Clover seeds are the cheapest, for they not only produce a better but a much more robust and vigorous plant than small, badly ripened stocks, which are never cheap at any price.

There is only one kind of Ryegrass worth growing for sheep grazing in our opinion, and that is Foster's Dwarf Italian. Ewes are well and healthy, lambs are plentiful and strong, all they want now is mild spring weather.

A WONDERFUL MILKING RECORD.—A noteworthy milking record has been established by the red poll cow Crocus, which belonged to the famous Norfolk dairy herd at Whitlingham. She gave birth to her third calf on May 11th, 1890, since which date she continued uninterruptedly in milk till September 28th, 1899, a period of over nine years, her milk yield in the last week of her life being at the daily rate of $43\frac{1}{2}$ lbs., or nearly $4\frac{1}{2}$ gallons. During the nine years four months that she was continuously in milk she yielded altogether 50,428 lbs., or nearly 23 tons of milk. Over the last five years the average quantity of butter-fat in her milk was as high as 4.3 per cent. Her live weight when sent to market, after being on grass feed for the last six months of her life, was 10 cwt. 1 qr. 11 lbs. In the nine years since her last calving she gave something like forty-five times her own weight in milk, and her average production during that period was 5,403 lbs. of milk, or considerably over 500 gallons per annum. For a moderate-sized cow this is, says a Scottish paper, a remarkable performance, which has aroused much interest amongst the breeders of red polls.

AGRICULTURAL AFFAIRS IN NEW ZEALAND.—A correspondent from Blenheim, Marlborough, New Zealand, writes, dated 16th October:—We have got all our crops in, and they are looking beautiful; in fact, we have never seen the crops looking better than what they are at present. We hope prices will have an upward tendency compared with last year. The Massey-Harris binder is the one most extensively used hereabouts, and does its work splendidly. Barley has proved the best crop this season, and this is chiefly owing to the fine dry weather we have experienced. The prices for Wheat, however, are unfortunately no better than last year so far. The Government have opened up a large block of land, in all about 35,000 acres; this they cut up into sections, running from 50 to 1000 acres. The most of the ground, though of a light quality, is nearly all ploughable. The rents run from 2s. to 6s. per acre the half year. The lands are on the perpetual lease system of 999 years, and they are not allowed to take more than two crops in succession off the same ground, but they are allowed to take one root crop as well, making three crops in all.—(“North British Agriculturist.”)

POULTRY FARMING.—In auctioneers' advertisements one often comes across the announcement of land “suitable for poultry farming.” I believe, in that profession, any land useless for any other purpose is declared suitable for poultry; a bare, bleak, wind-swept field can be thus described, whereas it is nothing of the kind. A well-sheltered piece of land, with an adjoining shrubbery or plantation for raising the chickens in, is a great point to the good in starting. There are, however, many points to be considered. I once rented an almost ideal site for poultry keeping. Part sloped to the west, the rest was flat, sheltered on all sides by hills. There was a small plantation, good hedges, and a little stream ran through one field. There is always a drawback; in this case it was that the land was a third of a mile from the house, a point I did not sufficiently consider when I took it. But anything is better than exposed sites, for, apart from the extra expense of building shelters, the fowls never lay so easily as their more fortunately situated kindred. Never, says a contemporary, take a land agent's view of a suitable poultry site, but use your own eyes and intelligence. Moreover, get fresh land, unless you see the fowls running over it are absolutely healthy.

BARR'S SEEDS

OF FINEST SELECTED STRAINS
AND TESTED GROWTH.

NOVELTIES & SPECIALITIES FOR 1900.

Amaryllis, Barr's Choice New Hybrids, saved from a magnificent collection. Per packet, 2/6.
Aster sinensis, a lovely single Aster, with large handsome flowers of a delicate mauve with yellow disc, bushy, branching habit, ht. 15 in. Per packet, 1/- and 1/6.
Candytuft, Barr's Giant White, very large spikes of snowy white flowers. Per packet, 6d. and 1/-.
Celosia plumosa, Barr's Choice Mixture, handsome feathery plumes of bright colours. Per pkt., 6d. and 1/-.
Lantana, Barr's New Dwarf, a mixture of brilliant colours, charming as a pot plant. Per packet, 1/6.
Lupinus arboreus Snow Queen, a pure white Tree Lupin, fine novelty. Per packet, 1/- and 1/6.
Mignonette, Barr's Covent Garden Favourite, the finest Mignonette for pots or borders, the handsome flower heads are deliciously fragrant. Per pkt., 6d. and 1/-.
Nicotiana sylvestris, a fine white-flowered Tobacco with handsome foliage. Per packet, 6d. and 1/-.
Petunia, Barr's Superb Giant, the largest and handsomest of all the Petunias, immense flowers of rich and varied colours. Per packet, 2/6 and 3/6.
Phacelia campanularia, one of the most lovely blue flowers in cultivation, height 8 in. Per pkt., 6d. and 1/-.
Poppy, Empress of China, snow-white single flowers, with a fringed margin of crimson-scarlet. Per pkt., 6d.
Poppy, Shirley, Barr's extra selected strain of this beautiful annual Poppy. Per packet, 1/-.
Rose, Miniature Fairy, dainty little semi-double flowers of various shades, blooms first season. Per pkt., 6d. & 1/-.
BARR'S SEED GUIDE contains a Select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

ONLY GENUINE DIRECT FROM WEM

AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The **BIGGEST SUCCESS** of all is **ECKFORD'S GIANT SWEET PEAS**. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40!

Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that **ECKFORD'S SEED**, for PURITY, VIGOUR, and YIELD, are the **CHEAPEST** and **BEST** ever offered to the Public! Collection for 12 months supply, 1/6, 2/1, 4/2, 6/3, 10/5, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties
PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLAKED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it!

SEED GROWER, WEM, SHROPSHIRE.

BEGONIAS, TUBERS & SEED.

THE BEST COLLECTION. Catalogues Free.

Seed, Double and Single, choice, each 1/6 and 2/6 per pkt. Extra Superb Hybrid, from newest and best flowers only, each 5/-.

B. R. DAVIS & SONS, YEovil NURSERIES, YEovil, SOM.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirits to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE" is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

"WEST'S INSECTICIDE" can be proved to be the best and cheapest by sending for a free sample box.

For particulars of West's Patent "Ivory" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Crocks, West's Fertiliser, West's Weed Killer, West's Lawu Sand, &c., &c., see ILLUSTRATED CATALOGUE OF WEST'S PATENT GARDEN SPECIALITIES, post free.

Samples free; postage for samples and goods extra. All goods made on the premises by C. E. West.

Gratis, "Orchid Culture," 3rd Edition, postage 2d. Gives full particulars of the cultivation of Orchids.

THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS

Journal of Horticulture.

THURSDAY, MARCH 22, 1900.

The Garden and the House.

IN olden times gardens were never detached from the house, but were invariably delightful appanages of the dwelling. They were not gay in our sense of the word, but they were eminently jolly, with pleached alleys and Honeysuckle covertures, where inquisitive Beatrices could snugly hide and listen; with lengthened arbours where a studious Bacon could walk on sunny days; with elevated mounts from which the surrounding country could be viewed; and with thick hedges pierced at intervals to form recesses in which stood orators, as did Savanarola, to stir with burning words the audience grouped on the walks and alleys around. It was in the gardens, also, that musicians in the time of summer rendered the latest thing out to their patrons.

Its crops were different from ours. Necessarily so, for while we consume vegetables and fruits as foods simply, in those enlightened days the physical qualities of the denizens of the garden were first of all inquired into, and so we find all old gardening books devoting as much and sometimes more space to the medicinal virtues of the plants of which they treat as to their cultivation. Violets in this way were valued as much for their use in pottage as for their sweet smelling flowers, and the common Nettle for the same reason stood on an equality with the Cabbage. In a word the garden, in its crops, as in the uses to which it was put, was very largely an indispensable adjunct to the house, as it was by means of the fruits, flowers, and vegetables it produced the dispensary from which its inmates derived medicines for all sicknesses and salves for every kind of wound and sore.

But by degrees the garden became less a necessity and more a detached piece of ornament. Its flowers were not gathered for distillation, its herbs were scattered as of no worth, and the list of its useful vegetables was greatly curtailed. Gardeners passed their days in a leisurely, dreamy existence. Their staff "took" the harvest and hoed Turnips "by the piece" in the fields of neighbouring farmers,

returning to the garden in the intervals to put in crops and "hough" the weeds. The massing of colours in flower beds, with the disappearance of duty on glass, was the means of bringing unremunerative gardening to its highest pitch. Flowers out of doors and "under" glass alike were produced almost solely to look at, and, no doubt, many of us can yet remember the horror gardeners felt if flowers had to be cut, and I notice that aged proprietors of gardens still reluctantly allow flowers to be so used.

It is plain, however, that we have arrived at a period when the relation of the garden to the house, in at least some aspects, has become as close as it was 250 or 400 years ago. The garden is now more largely than ever a place for the production of material to be used in the house. As many vegetables as formerly are consumed, and much more fruit; but it is in the two items of plants and flowers, which previously were only sparingly employed, that the greatest increase is apparent.

The objective of plant culture has been completely changed, and we do not now produce large specimens as a proof and example of cultural skill, but solely for the use they can be turned to decoratively. Small plants instead of hardly being grown at all have become a constantly pressing necessity, so that in place of one or two large examples of a species which were cultivated for many years and became objects of affection to the grower, dozens or hundreds have now to be produced in the course of a few months, to be then utilised, and not infrequently immediately thereafter thrown away. The system is essentially a wasteful one and fatal to sentiment. The methods of flower production and the ways of employing the flowers are much the same as with plants. Quantities of particular varieties in uninterrupted succession to be used in profusion in the adornment of the house, form the chief end in view. Consequently there is little room for sentiment to expand here either, which is a pity, because the best results cannot be obtained in plant culture in the absence of sentiment.

But when we think of it, there is space for the exercise of as much skill, though of a different kind, in the production of a nine-month "Geranium" as there is in a specimen of a few years old. The one can be produced alone by intelligent and unremitting care, and exactly the same virtues go to make success in the other. From the selection of the cutting in spring till the day the little plant, perfect in leafage and bloom, takes its place in some decorative scheme in autumn, the exercise of qualities of a high order are constantly kept in play. The depressing element, with young people especially, arrives when, after a week or two in the house, the plant returns a wreck; and when this condition is usual from week to week and month to month, the interest in work inevitably slackens.

It must be the business of the head to arrange that this waste of material shall be reduced as far as possible. Care in watering while plants are in rooms is essential, but it is of still more importance that no plant be allowed to remain long enough to suffer bad effects. It will often be found that not only in different rooms do plants exhibit varying effects, but in large apartments plants stand in good condition for a longer time in one place than another. The greatest source of waste in cut flowers arises from unskillful gathering or from ignorance of the nature of the flower. Gardeners err sometimes, but it is by members of the family who like to gather their own flowers that the greatest waste follows. It is no uncommon thing in such cases to have plants pulled up by the roots, foliage shorn over, and when this happens in the case of Freesias, Gladiolus, and even Orchids, the mischief requires no completing.

A most unhappy result of the garden having become so largely a mere manufactory of material for use in the house is the tendency in some quarters to allow the kitchen garden to sink into a condition of semi-neglect. One occasionally finds it rougher than a field, and too often with dirty walks, unkept, or no edgings, and a general air of untidiness that is unsatisfactory. The reason is, of course, that this garden is really a manufactory, and utility with thrifty management ought to rule. Personally I think this is a mistaken view. A kitchen garden can be managed economically, while at the same time sufficiently well kept to be a pleasure to stroll about in. Its borders may be as

profitably, while more ornamentally, filled with flowering plants—Roses and Pæonies—as with Turnips or Potatoes. We certainly cannot stay the ever growing tendency to utilise every department of the garden as a feeder to the house, but that is no reason why we should on that account allow the garden to deteriorate in any way of degree.—B.

Notes on Clematises.

THE Clematis is one of the quickest growing of hardy climbing plants, and is well adapted for covering spaces on walls or buildings, clothing pillars, porches, trellises, arbours, tree trunks, or ruins. These positions will soon be occupied by the growth of the most vigorous kinds, and in spring and summer, or towards autumn as the case may be, a profuse display of flowers will result.

Clematises are divided into groups, termed *florida*, *Jackmanni*, *lanuginosa*, *montana*, *patens*, and *viticella*. Each of these groups possesses characteristics of its own, and to insure securing the best results from the plants the style of growth must be considered, and the time of blooming. Pruning is then carried out in a manner suiting each group, as some flower most freely on the old or ripened wood, while others do so the best on the new wood.

Taking first the *Jackmanni* group, which is probably the best known and most generally used. The varieties in this are summer and autumn blooming, and produce the flowers on new wood between June and October. This allows them to be pruned-in closely each spring. The space allotted to the growths may be covered with a series of main shoots, and the side shoots emanating from them pruned back to within a few buds of the main growths.

The *florida* group produces all double-blooming varieties, which flower between May and July. The ripened growths of the previous year ought in this case to be laid-in freely, shortening them only where space does not permit of the shoots being laid-in further or they are not ripened.

The *lanuginosa* type has flowers of large size, produced in summer and autumn. Practically the previous year's shoots may be retained, with the exception of cutting off about one-third. The blooms come on short lateral shoots, which issue in summer, hence the necessity of retaining the older growths, from which they may be produced.

The *montana* section produces small flowers, but they are very numerous and attractive in the axillary clusters, which spring from the old or ripened wood, plenty of which should be retained each season. As a rule this group receives very little pruning, and is the best type for covering any unsightly object in wild profusion. A grand display of bloom results in May and June.

The next group or *viticella* is a large flowered summer and autumn blooming type, commencing in July and ending in October. The flowers are produced successionally in masses on the new wood, therefore it is best to adopt fairly close pruning. In some positions, or where the flowers are wanted low, cut the plants down to within 2 feet of the soil, but to effectually clothe higher positions the plan recommended for *Jackmanni* type—namely, securing a series of main growths or stems and pruning back the annual growth each season, proves good. The *patens* section, also large flowered, blooms from the old wood during May and June. Prune weak or exhausted wood away, and shorten the tips of the shoots retained.

Clematises pay for generous treatment in regard to providing a liberal root run where the roots may ramify in rich soil. It is desirable to trench or dig the ground deeply, taking out a double spit of soil about 2 feet square for each plant. Break up the subsoil and return to the space a mixture of equal parts of good loam of a turfy character, leaf mould, decayed hotbed manure, and coarse sharp sand. Introduce this compost, making it firm, and plant during April. Spread out the roots as far as possible, covering them carefully with fine soil, and distribute them well in preference to bundling them together. All the varieties will be best pruned rather closely after planting in order that vigorous growth may be produced.—E. D. S.

Burford Lodge.

THERE is probably no collection of Orchids in the whole world more celebrated than the one that has been brought together by Sir Trevor Lawrence, Bart., the well known President of the Royal Horticultural Society. As one of the keenest of amateur enthusiasts, Sir Trevor has spared nothing that would tend to make the stock representative of the entire Orchid family. His powers of appreciation are obviously much more highly developed than is the case with many people, for he can find delight in examining some minute member of the floral kingdom which the ordinary observer would pass without a glance. Thus it is that during the past quarter of a century, or perhaps more, the collection has been growing steadily in what are generally designated botanical curiosities, until at the present moment it is one of the most complete that is known. But Sir Trevor Lawrence carries his interest in the Orchids further than in expressing admiration for flowers, small and large; he makes himself familiar with their names, habitats, parentage, and in fact becomes thoroughly conversant with them all. This must all of course tend to increase his interest in his stock, and the Burford Lodge collection as a natural consequence continues to increase in variety and extent.

It is unquestionably very fortunate for the ordinary visitor that this gentleman does not limit his admiration to the dwarfs amongst these aristocrats of the world of flowers, but includes other kinds of more decided beauty. As a matter of fact it is apparently the aim to have examples of every Orchid that, having been brought into the country, can be got to Dorking alive and be made there to grow and flower. House after house is completely filled; the central and side stages positively groan beneath their burdens, while the roof rafters are well nigh obscured by the number of pots, pans, baskets, rafts, sections of trees, and other things that hang from them, and every one of which contains an Orchid. In one place you see a basket about 4 feet in diameter containing the pure white form of *Cœlogyne cristata*, and in another a pot of the size of a thimble, in the centre of which is a plant about a quarter of an inch high that some day may, or may not, rouse the English Orchid world to ecstatic enthusiasm.

A few days ago I had the pleasure of paying my second visit to Burford Lodge, and under the guidance of Mr. W. H. White, the Orchid grower, looked through the several structures. Some were full of beauty in the form of flowers, and others in growth and leaves alone, and it is no easy matter to decide where to make a start, as the latter, if we take excellence of health as a starting point, were quite equal to the former. However, it is not to be supposed that hundreds will be named, so we can refer to them as they were found, irrespective of whether they were carrying flowers or not. Before actually naming any particular plant it will not be out of place to pay a tribute to the cleanliness that prevails throughout the houses. Everything that can be washed or scrubbed is evidently done, with the result that pots, pans, stages, floors, and other surfaces are scrupulously clean. This must exercise a beneficial influence on the health of the plants, and certainly the appearance of the plants is improved by the condition of their receptacles. The leaves, too, are in the best state, and this close attention to a very elementary detail accounts to a certain extent for the results that are achieved.

Let us at the outset glance at the *Dendrobiums*. The major portion of these are accommodated on the side stage of a large span-roofed structure, and the effect produced by the massed plant is beautiful. There is an imposing stock, but the results are gained not so much by numbers as by individual excellence of the plants, many of which are perfect examples of what a well-grown *Dendrobium* should be. The plants are the picture of health, and the number of flowers carried by some of them is little short of remarkable. Charming little specimens in 6-inch pots are producing about a hundred flowers, and those of dwarfer habit would make simply ideal plants for use on the table. There are, of course, many *Dendrobiums* in other houses, but these are of different type, and call for other treatment from that meted out to those under notice. Mr. White ascribes his success in a large degree to judicious watering, scarcely any being given to the plants during the winter. Occasionally a supply may be deemed imperative, and it is then given just within the rim of the pot, and never in the centre, as is commonly the case.

In passing slowly through the *Dendrobium* house a few names were jotted down, the most attractive, from some particular aspect, being chosen. One so distinguished was *Burberryanum* (fig. 64), which was honoured with an award of merit from the Royal Horti-

cultural Society on March 13th. Seeing it at the Drill Hall and at Burford Lodge are two very different things, for at home the striking beauty of the flowers is fully appreciated. The red, or perhaps very brilliant rose, describes the colour better, of all the organs, and the excellent form of the flowers were sufficient warrant for the recognition given by the Orchid Committee. *D. Burberryanum* was raised in the collection of the Right Hon. Joseph Chamberlain, Highbury, from a cross between *D. Findleyanum* and *D. Dominianum*, and in 1897 a small piece was presented to Sir Trevor Lawrence, which is now flowering for the first time. Amidst a collection of superb forms this hybrid makes its presence felt by the intensity of the colour of its flowers.

There are many forms of the attractive *melanodiscus* at Burford Lodge—some superior to others no doubt, but every one quite worthy of its place. One example of this *Dendrobe* in a 32-pot carried 106 perfect flowers, and this knowledge will convey to readers an excellent idea of its beauty. Another variable plant is *D. splendidissimum grandiflorum*, of which the type stands head and shoulders above its fellows in colour, size, and substance of the flowers. The colour in the throat of *D. nobile Amesiae* is marvellously deep, and runs quite through the flower; while in the Burford Lodge variety of the same popular Orchid we find a peculiar streak of colour down the petals, that gives the flower a very distinct character. Of softer beauty is *nobile Ballianum*, and in *nobile Tollianum* may be found one of the curiosities of form. The plum-coloured throat of *The Pearl*, hybrid of which the parentage is unknown, is unique, and is

FIG. 64.—*DENDROBIUM BURBERRYANUM*.

beautifully set off by the delicacy of the prevailing colour of the flowers. Two really exquisite *Dendrobiums* are *Luna* and *pallens* (fig. 65), both of which are of fine form and very floriferous. In each case the colours are very soft, as the varietal names imply. A few more included in either this or other structures, *tortile*, *senile*, *Hilli*, *Treacherianum*, *Rolfæ*, *xantholeucum*, *Clio*, *signatum*, *Cassiope*, *aureum*, *Jerdonianum*, and *Kingianum*.

Burford Lodge has a great reputation for its *Masdevallias*, of which there is a magnificent collection. On the occasion of a previous visit exceptionally large plants were fairly numerous, but these it was learned have been presented by Sir Trevor to Kew. Their loss does not mar the excellence of the collection in its range of species, hybrids, and varieties, and its interest is practically perpetual, as there is always something in flower. All the plants are in excellent health, and prove conclusively how they appreciate the attention accorded to them. Equally satisfactory in their way are the *Aërides* and *Saccolabiums*, though this is not the best season at which to see them. In the same structure as these the curious *Angraecum pertusum* was flowering profusely, as was *Spathoglottis Lobbi*, whose flowers are carried on such slender stems that one is surprised they will bear their delightful burden. *Chysis Chelsoni* with its handsome flowers was conspicuous, while a small plant of the white *Dendrobium nobile* called for attention.

One half of the large span-roofed house in which the *Dendrobiums* are luxuriating is occupied with various Orchids, amongst which was a grand specimen of *Vanda Sanderiana* on a large raft. A curious fact relative to this plant was mentioned by Mr. White. It appears that some time ago, when the plant occupied a different and less accessible position from that at present assigned to it, a quantity of green growth was observed amongst the roots. On the occasion of one

of his frequent visits, however, Sir Trevor also noted the fact; and, not content with a distant view, mounted the steps and stage for a closer inspection, which revealed the fact that the growths which had been taken for moss were really small plants. At least two of these remain on the roots, and the remainder have been placed in small pots to grow. Whence these seedlings came, and what the plants will prove to be, are equally unknown, but the latter will, it is hoped, be elucidated in the future. *Vanda coerulea* is flowering in another position in the same structure, while the handsome *V. coerulea* finds an apparently congenial place in another house, where it is hoped it will flower freely. The green-leaved *Phalaenopsis* grow apace, one plant having made eight leaves during the past twelve months; the marbled-leaved types also look wonderfully well. There are hundreds of other plants in this house alone.

Occupying a position in front of an immense basket of the pure white form of *Coelogyne cristata* are some plants of *Laelia harpophylla*, and the combination of colour is peculiarly pleasing. *Laelia Cowani* is also close by, as are *Lewisias*, though the latter are not in flower. Proceeding, we find numbers of *Epidendrums* in various places, including *radicans*, *Endresii*, *elegantulum*, *Endresii-Wallisi*, *xanthinum*, and others, besides *Vanilla Wightii* in flower, and *Maxillaria leptosepala*, *Promeneia citrina*, *Angraecum eburneum*, *Cymbidiums*, *Cattleyas*, and *Odontoglossums*. So one might go on naming plant after plant, until long ere finis could be written several pages of the *Journal of Horticulture* would be covered. There are the plants and there it is hoped they will remain and continue in the same excellent health that characterises the majority of them at present, despite the fact that Box Hill frowns above and deprives the garden and its occupants of much light and air.—ORACHE.

Dendrobiums at Woodhatch, Reigate.

I SAW a really wonderful show of these beautiful Orchids in flower a short time ago at the above place. Mr. Haywood had probably just then one of the finest displays of Dendrobiums to be seen anywhere, some 300 being in bloom, of which not less than 200 were seedlings, raised by Mr. Salter a few years since, from several crosses. But apart from their being such, there was great interest attached to their splendid condition.

This first set of seedlings were between four and five years old, and were all in 32 and 24-sized pots, with the exception of a noble plant of the variety "Virgil," of which form there are many, and which was in an 8-inch pot, carrying several fine spikes. Growth of the latest production ranged from 20 to 40 inches in height, and were proportionally stout. Possibly being so far maiden plants they have in them greater robustness than propagated ones have, but that is not certain. In any case the culture is of the very best. The plants have ample light and air, and are kept rather cool than warm. The houses, for they occupied three in one long lean-to range, are scrupulously clean and comparatively dry. No stimulants are used, and the sole rooting medium is sphagnum moss, with a few crocks.

It was difficult to look upon such an unusual sight of *Dendrobium* florescence without a pang, on hearing that large numbers of these plants would be offered for sale by Protheroe & Morris on the 16th inst. The present collection has come from *Ainsworthi* × *nobile* roseum, which has produced the beautiful white "Virgil" strain; *heterocarpum* × *splendidissimum*, and *Ainsworthi* × *heterocarpum*. Some specially fine forms will not be parted with at present. Another stock of seedlings yet in small pots has been raised by crossing other and possibly choicer varieties. Mr. Salter's success has been remarkable, and if he worked on a liberal scale could soon make *Dendrobium* plants for the million. But orchidists do not want that to occur.—A. D.

In Cheapside.

WERE it not for the fact that the great horticultural auctioneering firm of Protheroe & Morris has its headquarters there, people would hardly look for Orchids in Cheapside. The result of this location, however, is that at various times many valuable Orchids come and go; in fact, some of the most important Orchid sales in the world take place there. Naturally enough, these vary in extent and importance, but there is usually something of interest at every weekly meeting. There are those among Orchid enthusiasts who set Friday entirely apart, so that they may not be debarred from attendance at Cheapside. They may not always be buyers, but their interest is so keen that they must go, and if they do not enter into the bidding, derive satisfaction from knowing who does. Some of the *habitués* buy for their own collections, while others accept the work on commission, and amongst them may be found men whose knowledge of the commercial value of Orchids cannot be surpassed, and probably is unrivalled.

On Friday, March 16th, many exceptionally important lots were to come under the hammer, and we made our way to Cheapside as spectators of men and manners. The sale room was a veritable paradise of *Dendrobiums* from Surrey, *Phaius* from the Tyne, *Odontoglossums*

from Belgium, *Cattleyas* and *Laelio-Cattleyas* from France, and hundreds of others from various quarters. Buyers, too, were numerous, and while they were apathetic enough when plants of mediocre merit—in the eyes of experts—were to the fore, they were wonderfully keen in scenting out anything above the ordinary. The nods and winks, of which the bidding appeared mainly to consist, were then rapid—at least this was the conclusion arrived at from the celerity with which the presiding genius ran up the scale of figures. For one *Dendrobium* a bidder calmly offered 8s., and retired from active participation when 15s. was reached; the plant was eventually knocked down at 4½ guineas. It was not much to look at, but the experts, in everyday parlance, "knew something."

Amongst the conspicuous lots were a splendid specimen of *Eulophiella Peetersii*, which a buyer was fortunate enough to secure for 20 guineas; the chastely beautiful *Dendrobium nobile Virginalis*, carrying about two dozen flowers, which remained unsold at 74 guineas; a hybrid *Odontoglossum* which fetched 20 guineas, and *O. Loochristiense*, 24 guineas. A plant in sheath of *Laelio-Cattleya Digbyana-Mendeli* (*Imperatrice de Russie*), from Mons. Ch. Maron, reached 90 guineas and remained unsold, as the reserve was 100 guineas, but it was said, subsequently changed hands at 50 guineas, at which figure it was secured for Lord Rothschild, who was indeed, by proxy, a large buyer. *Laelio-Cattleya Ernesti*, carrying three flowers, fetched 32 guineas, as also did *L.-C. Lucasiana*. *L.-C. Captain Percy Scott* and *L.-C. Minerva* brought 20 guineas and 15 guineas respectively, and *L.-C. Edouard André* 28 guineas, these being some of the heaviest prices. A number of plants of *Odontoglossum crispum*, *Pacho* type, in splendid condition, from Mons. Florent Claes, ranged between 10s. and 15s. apiece and sold rapidly. With a few exceptions the well grown seedling *Dendrobiums* did not realise high prices, partly because several were not of superlative merit, and partly because they were so numerous. As an example of the fluctuation it may be said that one set of three realised £3 15s., and another set only 6s. Some of the plants of *D. Virgil* went well, as did the Woodhatch Lodge variety of *D. Ainsworthii*, while *D. Ballianum* fetched 7½ guineas.

And so we might proceed naming price after price, but space forbids. There were quality and quantity both largely represented, and the interest in the sale was excellently maintained. The proceedings were quiet as a rule, but an occasional flash of humour helped the Orchids in brightening the sale room and its occupants.

A Great Specialist.

THE late Mr. Edward Joseph Lowe, whose death was recorded last week, was a specialist of an exceptional character, and besides his numerous personal friends, all Fern lovers and students will unite in sincere regret at the loss we have sustained. As a cultivator and collector of the varied forms of British Ferns he was indefatigable and successful, but beyond this he was a philosophical and scientific experimentalist and investigator of rare patience and persistence. Of the numerous works Mr. Lowe had written the most recent was perhaps the most interesting—namely, "Fern Growing, Fifty Years' Experience in Crossing and Cultivation." In this book he detailed his experiments in hybridising and crossing Ferns, and sets forth reasons and facts in support of multiple parentage, which have attracted wide attention, though all pteridologists do not agree in the conclusions at which he arrived.

The other works on Ferns which we owe to his pen are entitled "Our Native Ferns," "British and Exotic Ferns," "New and Rare Ferns," and "British Ferns, and Where Found." Some of these are finely illustrated by coloured plates, and constitute a library of Fern lore, unrivalled as the work of one man. Other works of horticultural interest which Mr. Lowe produced at intervals are "British Grasses" and "Beautiful Leaved Plants."

As one of the founders of the Royal Meteorological Society in 1850, Mr. Lowe did further good service; he devoted much time for many years to meteorological work, and he was the author of several treatises on weather observations and phenomena. In addition to being a Fellow of many scientific societies, he had received some well-merited honours in recognition of his biological work. He was elected a Fellow of the Royal Society in 1867, and an honorary life Fellow of the Royal Horticultural Society in 1872, the year in which he acted as honorary secretary at the Nottingham meeting. At the Nottingham meeting of the British Association in 1866 he was also appointed honorary secretary.

Mr. Lowe was born at Highfield House, Nottinghamshire, on November 11th, 1825, and removed to Shirenewton Hall, Monmouthshire, in 1880, where he continued the studies which gained him so much fame in Nottinghamshire. He was essentially a true naturalist, and, apart from his botanical investigations, he was much interested in Conchoology, while amongst the numerous achievements chronicled in one of his works he claims to have been the "discoverer of a new British worm."—R. L. C.

Notes on Winter Apples.

THE stock of sound dessert and culinary Apples is in many gardens very low at the present time. This is not brought about by any deficiency of varieties that will keep until this period, but is rather the result in some instances of the crops being light from the visitation of spring frosts last year, and again, that in many gardens

Grafting is the quickest means of transforming early or midseason into late fruiting sorts, and it is just as desirable to purchase grafts from the nursery as trees when transformation is the object in view. Much more could be done than is at present effected by grafting, but the gardener in charge is not always allowed to exercise his own discretion in thus dealing with the established stock. A wide selection of varieties for late use is neither available nor necessary. By available, is meant in ordinary cases or in small private gardens. Messrs. Bunyard & Co., from their thatched fruit room at Maidstone, can

FIG. 65.—DENDROBIUM PALLEUS. (See page 239.)

too few late ones are planted.* It is no uncommon experience to find in gardens an over-abundant supply of autumn and early winter Apples, but less thought is given to the useful late ones in planting. Nor is it always an easy matter for a gardener to make radical changes in this respect, involving as it would the loss of fruit for consumption at some period of the season, whether replanting or grafting is adopted. When a garden is furnished with good-sized trees, neither gardener nor owner cares to see them removed, and their places occupied with young trees which require some years to attain to a profitable size.

easily retain the midwinter sorts for spring use; this, of course is an exceptional case that is not in many instances within the means of the private gardener to imitate. Messrs. Bunyard's exhibits in the spring months are most remarkable, and have puzzled many in the freshness of the out-of-season varieties that are shown.

In former times, and even now, there existed a desire to make the collection of fruit trees as exhaustive in variety as possible; certainly this could not have been because it is necessary for maintaining a supply for cooking or dessert. This latter is rendered infinitely easier

when there are larger stocks of individual and trusted varieties than from smaller gatherings of greater range. For cooking purposes this is even more true than when applied to dessert Apples. Variety in the daily dessert is always more or less welcome, but in cooking it is not so when the best for the particular purpose is on supply. It is quite unnecessary to particularise those which in ordinary cases are out of season, but mention might be made of a few that are still fresh and indispensable.

Though small, the old Cackle's Pippin is an invaluable dessert Apple for present use; ordinary samples possess no particular external beauty, but its crispness, clear-coloured flesh, and delicate flavour combine to make it a favourite with those who are so fortunate as to possess a supply. Mannington's Pearmain is another good Apple that ought to be freely grown; its habit makes it especially suitable for garden culture in bush form. Ribston Pearmain is not often met with, but is a splendid keeper, and has a fine appearance as well as flavour to recommend it. Court Pendu Plat is good, though not equal to the last named in quality, but it has the rare merit of flowering after many others are over, and thus escapes the destruction of its flowers by frost.

Cobham still retains its freshness, as also does Newtown Pippin. Claygate Pearmain has furnished beautiful samples from Christmas until now. When well coloured, this is an ideal winter dessert Apple, the appearance, size, and quality being all that can be desired, as is also the character of the trees' growth. Sturmer Pippin has been so often praised that more need not be given here. Reinette du Canada, too, if carefully harvested, is good for both dessert and cooking purposes. Gathered too soon, however, it is easily spoilt through shrivelling. Allowed to hang on the trees as long as it is safe, the fruit lasts well into the spring months.

In the matter of cooking Apples, much depends on the trees, soil, and fruit store whether they keep satisfactorily, this applying even to those that are reputed late. From old trees that are deeply rooted large fruits do not keep well; indeed, by midwinter many become spotted, a direct indication of a short season of usefulness. Young trees with their roots near the surface produce clean and better keeping fruit. Some soils, notably those with a cold, clayey subsoil, are not good for producing late Apples, unless the roots are kept near the surface by periodical lifting or root-pruning. Lane's Prince Albert, Wellington, Northern Greening, Norfolk Beauty, and Easter Pippin are good late cooking Apples. Norfolk Stone Pippin is a regular bearing variety, and though not of high quality, or large in size, is valuable, because it rarely fails to bear. There is no other that can be so well depended on in these gardens to produce a crop, and more often a heavy than a light one.

Size of dessert Apples has often been a debatable question, though, generally speaking, it yet remains unsettled, for there are few who admit the necessity of large Apples for the purpose, or appreciate them at the table. Though this is true as affecting the dining-room, the case is often different when visits are paid to the fruit room. Large Apples or Pears are commonly chosen if it be of good appearance, in preference to a smaller one. In this case there is freedom from formal etiquette, and if a large Apple proves too much, it can be thrown aside when the appetite is appeased without further thought. Nor is quality in such cases so strictly essential—indeed, one with a showy complexion is more tempting than a really good quality fruit unpossessed of skin beauty. I had ample testimony during the past winter bearing on this particular subject. Cox's, Ribstons, Blenheim, Claygates, and other high quality sorts were passed over in the fruit room for Heavy Morning, which in appearance is simply perfection—that is when it is in its best form. Mr. Banyard considers the quality so indifferent, that although he has it in stock, he does not include it in his catalogue.

Although quality should be made the first essential, I think I have advanced sufficient to show that high flavour, when concealed beneath an unattractive skin, is not so appreciated as it should be; and it is only another case of the grower and consumer being slightly in conflict. There are certainly two classes of consumers—one that will prize quality at all costs; the other is beguiled by handsome appearance more than by flavour. This is not only true of Apples, but of nearly all other fruits as well; and the same principle applies to other comestibles. Who, for instance, among purchasers would pick out all the small eggs out of the basket, because they were of better value than the larger? and how often does one hear the remark that the brown-shelled are richer than the white?

There is no doubt that colour in Apples can be improved by treatment of the trees, both in summer and winter. The produce from trees allowed to become densely crowded can bear no comparison with fruits from branches so disposed that the sun can readily reach the fruit. Summer pruning in trees sufficiently vigorous as to require it makes a considerable difference to the matured fruit, so much so, indeed, that in extreme cases I have known Apples to be almost entirely unrecognisable. Root-pruning has a wonderful influence on

the colour of Apples; big thong-like roots, penetrating deeply into the sub-soil, are not productive of this desirable feature—at any rate in garden trees; and their existence certainly adds to the labour of summer and winter pruning of the branches.—W. S., *Rood Ashton*.

Hardy Annuals.

As a general rule these require to be sown where they are intended to bloom. Very early sowing should be avoided, for nothing is gained by doing so, but, on the contrary, a very indifferent display will be the result. Early in spring the ground is cold and often wet, and these conditions combined sometimes destroy vitality, and under such circumstances the germination of the seeds committed to the soil is always slow. It may happen that mild fine weather prevails in spring; and when the gardener takes advantage of this to sow the various kinds of hardy annuals early, the seeds of some come up in a few days, but others remain in the ground a long time, and in many cases do not germinate at all. All seeds require a certain degree of heat to germinate; below that point they will not do so, but when placed in contact with moisture the same chemical process takes place within the seed, from the absorption of water, as if the seed were being transformed into a plant. When the chemical elements of a seed are thus changed, without growth or germination taking place, its vitality is gone; hence the importance of keeping seeds dry whilst in a temperature unsuited to their germination.

The middle of April I have found to be a good time for sowing hardy annuals. The temperature of the ground is then raised considerably by the sun's rays, and there is less probability of the soil being saturated with moisture, or the seeds receiving a check through snow, frosty weather, or cold drenching rains. From the middle of April to the first week in May I consider the most advisable time of sowing, and if possible a moist period just succeeding dry weather should be chosen. When the air is dry seeds of all kinds do not germinate so well as in moist cloudy weather. If it were possible to know exactly when rain would fall after dry weather it would be well to sow the day before; for it is all the better to put in seeds when the ground can be worked without making it into mud, as such a condition is unquestionably prejudicial to the success of any kind of seeds.

New seeds of all kinds are preferable to old for certainty of growth, for producing a stronger plant and a larger amount of flower, and new seed of all hardy annuals is decidedly preferable to old. It germinates sooner and with greater certainty; the plants are stronger, will bear more hardships, and produce finer flowers and in greater profusion.

The next point to be attended to in the cultivation of annuals is to have the soil in a condition suitable for the germination of seeds and the healthy development of the plants. How often do we see the borders only dug a few days before the seeds are sown, without any attention being paid to having the soil well pulverised, so that it will in the spring fall like so much flour after a shower of rain? The soil where annuals are intended to be grown should be dug deeply in the autumn, and left rather rough, so that air and frost may readily act upon it. A dressing of leaf mould dug in in the autumn is very beneficial. If the ground is at all heavy it will be much improved by forking it over on dry frosty mornings. This may be considered troublesome, but it is only what all plants require in order to grow well, and annuals are either worth growing well or not at all.

Just forking over borders in front of shrubs, and sowing annuals there without any further attention, is one of the best means of making them poor. They may grow and do well whilst young, and their wants small, but when these increase the soil is too firm for the roots to penetrate to any depth, or if they do the ground is already occupied by the roots of the shrubs, and very little food indeed remains for the annuals. I have heard them termed weeds, which they undoubtedly are as often cultivated; but bestow upon them the care necessary for their proper development, and they will in their season be found inferior to no bedding plant receiving double the amount of attention and expenditure.

In sowing the surface should be well pulverised with the rake, and a little of the soil drawn to two points, so as to leave a space of the size required for the patch, which should not be more than 1 foot or less than 6 inches across, and the patches should not be closer together than 1 foot in any direction. The seeds are best sown thinly in the centre of the patch, and more thickly round the edges.—PRACTICE.

(To be continued.)

NOTES & NOTICES

Recent Weather in London.—The weather of the past few days has been peculiarly varied. On Saturday we had snow both in the morning and evening, with sufficient frost to cover ponds with a thin sheet of ice. Sunday morning was fine, but the evening brought snow and heavy rain. On Monday morning the ground was thinly covered with snow, which did not remain long; in the evening there was torrential rain. Tuesday was brilliantly fine and spring-like, the sun being quite warm. At the time of going to press on Wednesday it was bright and pleasant.

Weather in the North.—In the earlier part of the week ending the 19th inst., high and cold westerly winds prevailed. Frost set in on the evening of the 15th, and 3°, 8°, 10° were recorded on the following mornings. Snow has again fallen heavily in several parts of the county, and a continuous onset for some hours on Monday forenoon covered the ground to nearly 3 inches. This, in great part, disappeared by the evening.—B. D., *S. Perthshire*.

Royal Horticultural Society.—The next Fruit and Flower Show of the Royal Horticultural Society will be held on Tuesday, March 27th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Some of the Plants Exhibited" will be given by the Rev. Prof. Geo. Henslow, M.A., at three o'clock.

New Agricultural College.—Recently there has been keen excitement about the gentry, with the Most Rev. Dr. Brownrigg, Bishop of Ossory, as chairman, who are taking the necessary preliminary steps to have the disused workhouse at Donoughmore converted into an agricultural college. The committee is an influential one, whilst the workhouse is eminently suitable for the purpose in view. The college is to be for the following counties—Kings and Queens, Tipperary, North and South Ridings, Kilkenny, Barlow, and Kildare. At the last meeting of the committee a resolution was adopted, and was directed to the heads of the Department of Agricultural and Technical Instruction, pointing out the great facilities which exist at Donoughmore for the establishment of an agricultural college.—A. O. N.

Elementary Education.—At a meeting of the Executive Committee of the Agricultural Education Committee, held at 10, Queen Anne's Gate, Westminster, S.W., on Tuesday, the 13th March, it was moved by Sir Wm. Hart Dyke, Bart., M.P., and seconded by Mr. A. C. Humphreys Owen, M.P., and carried unanimously, "That this committee hails with the greatest satisfaction the provisions of the new Day School Code adopting the system of 'block grants,' extending lessons on 'common things' to the higher standards, and requiring the course of instruction to be suitable to the circumstances of the children and the neighbourhood. They attach great importance to the new course of 'household management' prescribed for girls. Generally, they regard the alterations made this year as likely to prove most beneficial to country children, teachers, and school managers, and they trust that the Department may see their way to make corresponding changes in the forthcoming code for evening continuation schools."

National Diploma in Agriculture.—The Royal Agricultural Society of England and the Highland and Agricultural Society of Scotland have joined forces in the establishment of an examination in the science and practice of agriculture, to take the place of the separate examinations which have heretofore been held by the two societies independently. Candidates who pass this examination, which is under the management of the National Agricultural Examination Board, appointed by the two societies, are to receive the national diploma in agriculture. Those who obtain not less than a certain percentage of the maximum number of marks in each of the subjects will receive the diploma with honours, a gold medal being awarded to the candidate who is highest on the honours list. It has been arranged that the first examination for the diploma shall be held in the great hall of the Yorkshire College, Leeds, on Monday, April 30th, and five following days. Applications to be allowed to sit at this examination must be made not later than Saturday, the 31st inst.

Petersham Common.—Many readers will be glad to know that Petersham Common will very shortly come under the Metropolitan Commons Acts. The Board of Agriculture last year certified a scheme for the establishment of a local management with respect to the common, but such a scheme has not of itself any operation until it shall have been confirmed by Parliament, with or without modification. The confirming bill has now been introduced, and will, no doubt, have an easy and rapid passage through both houses.

Anatomy of Light.—At the Royal Institution, Lord Rayleigh, on Friday, continued his lecture on "Polarised Light." Full of the keenest insight into the facts connected with the phenomena, and aided by exceptionally successful experiments, the scientist unfolded the subject, showing at every point Nature's wonderful laws in relation to the phenomena—crystalline properties of light, and, notably, laws of colour based on the triangle of colours as expounded by Newton. The screen diagrams demonstrating all this, constituted a series of beautiful pictures.

Gardening Appointments.—Mr. G. Stotesbury, late head gardener to George Pim, Esq., Brennanstown, Cabinteely, has been appointed to a similar position in the gardens of Colonel Smyth, Gaybrook, Mullingar; Mr. W. Usher, general foreman, succeeds Mr. Stotesbury. Mr. W. McClatchie, for the past three years head gardener to Sir Ralph Cusack, Furry Park, Raheny, has been appointed head gardener to the Right Hon. Sir David Harrel, Under-Secretary's Lodge, Phoenix Park, Dublin. Mr. George Reid, for a number of years foreman in Kirklees Park Gardens, Brighouse, succeeds Mr. Herbert as head gardener to Miss Trevor, the Mount, Littlethorpe, Ripon.

St. Valentine's Day in Boston.—Valentine's Day in Boston, U.S.A., has always been a busy and profitable occasion for the florist. February 13th and 14th are equally busy with the wholesalers, the out of town trade buying briskly on the earlier date for demands of the 14th. Small flowers sell best, Violets leading everything else, but the demand really covers everything in the flower line and applies to all grades of the business. Flowers for Valentine gifts are sent almost invariably in boxes, a fancy card or valentine being laid on top of the flowers, and there is little or nothing done in the way of special design work or decoration. Last year was a most unfortunate one for the valentine trade, as the big blizzard struck in the day before, and, everything being blocked, people who wanted Violets had to go without, and the dealers missed the benefit of the much-needed business in the worst coal-eating season they had seen for many years.

Death of Mrs. Lawrenson.—With regret, that all who knew her will share, I have to announce the death of Mrs. Lawrenson, which took place at her residence, Salerno, Killiney, Co. Dublin, on the 14th inst. Better known, perhaps, under the *nom de plume* of "St. Brigid," her labours of love in the gardening world, which are inseparably associated with that fine strain of Anemones, may yet show further developments of her loving care and enthusiasm in other directions. Since leaving Howth—where she was laid to rest on St. Patrick's Day—to reside on the western shores of Dublin Bay, Hellebores and Narcissi had, among other things, claimed her attention. Of the former particularly this estimable lady was very hopeful and proud of a numerous progeny she had raised. These, we venture to hope, will fall into good hands now that Salerno—that lovely spot overlooking sea and mountain—knows its gentle mistress no more.—K., *Dublin*.

Gardeners' Charity Guild.—It is not every gardener in the United Kingdom who is aware that there is a "Gardeners' Charity Guild," or that this association has inaugurated concerts in aid of the gardening charities. Such, however, are bare facts, substantiated by the fact that last year the concert was the medium by which upwards of £30 was handed to the Royal Gardeners' Orphan Fund. This season, in order to continue the excellent work that has been begun, a concert was arranged for the evening of Wednesday, March 14th, at the Cannon Street Hotel, when N. N. Sherwood, Esq., occupied the chair. The great hall was well filled with people, who were in high good humour, and bent upon enjoyment. An admirable programme had been arranged, and the items therein were heartily received. The committee and Mr. T. Swales (hon. secretary) are to be congratulated on the result of their efforts. We have not yet learned to what extent the funds of the Gardeners' Royal Benevolent Institution have benefitted, but trust it will be a good round sum. Of this, we are informed, the honorary secretary will send particulars at an early date.

Royal Horticultural Society.—The Rev. W. Wilks writes: "On behalf of the Council of the Royal Horticultural Society, and in order to allay the anxiety that may be felt by the Fellows, I shall be obliged if you will publish the following statement:—The general meeting of the Society, held on the 13th ult., having unanimously adopted the proposal of the Council to celebrate the centenary of the Society by the removal of the Society's Gardens from Chiswick to some spot where the atmosphere is less charged with smoke, the Council have inspected several proposed sites, and have at least one still left to investigate. The business is not one which can be hurriedly done. As soon as all the suggested sites have been properly considered by the Council, a definite proposal will be duly submitted to the Fellows."

Horticultural Club.—The usual monthly dinner and conversazione took place on Tuesday last, the 13th inst. The chair was occupied by Rev. W. Wilks, and amongst those present were Messrs. Gofton, H. Salmond, George Bunyard, Alfred Rivers, Pinches, Selfe Leonard, and George Paul. The paper after dinner was on the hardiness of Tea Roses; it was read by Mr. Geo. Paul, V.M.H., whose long experience in the growing of this beautiful section enables him to speak with a good deal of authority. An interesting discussion (in which many of the members joined) followed the reading of the paper, and a cordial vote of thanks was given to Mr. Paul. The question has been a good deal before the public lately, and it is hoped that Mr. Paul's paper will appear in the "Rosarian's Year Book" for 1901.

Wolverhampton Horticultural Club.—At the recent monthly meeting, Mr. J. F. Simpson in the chair, Mr. W. Gardiner, Harborne, Birmingham, read before a large attendance of members letters from South Africa, descriptive of the geography of that colony, with interesting details of the ornamental trees, shrubs, and flowers. Mr. Gardiner prefaced the reading with a brief allusion to the chief genera of the flora, especially of Cape Colony, and to which we are so much indebted for the embellishment of our greenhouses and gardens.

Royal Caledonian Horticultural Society.—Amongst Scottish societies this occupies a very prominent position, and its shows in the Waverley Market are looked forward to by exhibitors and others both north and south of the Tweed. This year the spring show will take place on April 4th and 5th, and the autumn meeting on September 12th and 13th. These are the two principal events, but two smaller shows come in May and July. The September exhibition is the more important, and includes classes to the number of about 260 for practically every conceivable crop; at the spring show there are 136 classes. The secretary is Mr. P. Murray Thomson, 5, York Place, Edinburgh, from whom particulars and schedules may be obtained.

Birmingham Gardeners' Association.—At a recent fortnightly meeting, Mr. H. A. Burberry (late orchidist to the Right Hon. Joseph Chamberlain, Highbury), in the presence of a good attendance of the members, read an excellent paper on the history and culture of *Odontoglossum crispum* and its varieties. An animated discussion followed, in which there was a certain degree of opposition to the theory and practice advocated. Mr. W. B. Latham (curator of the Botanical Gardens, Edgbaston), the chairman, in adverting to the hygrometrical conditions pertaining to the culture of Orchids in general, advocated a very spare use of the syringe over the foliage of the plants, preferring the requisite moisture to be afforded atmospherically by syringing the walls and paths. The ailment commonly known as "the spot," was discussed, and was attributed to a low and over-moist temperature.

Chester Paxton Society.—One of the best attended meetings of the session was held in the Grosvenor Museum on Saturday, when Mr. D. A. Cowan of Gateacre Nurseries, Liverpool, delivered a lecture entitled, "Reminiscences of my Travels Collecting Orchids in South America," which was illustrated by a collection of South American snakes, butterflies, as well as several birds of exquisite plumage. In addition to these, added interest was given to the lecture by a collection of implements and dresses essential for the use of the explorer in search of orchidaceous plants in foreign countries. An interesting discussion followed, in which the chairman (Mr. John Taylor), Mr. Newstead, and Mr. Miln took part. Mr. N. F. Barnes, in proposing a vote of thanks to the lecturer, mentioned that Mr. Cowan and those associated with him in his business had perhaps done more to popularise the cultivation of Orchids in this country than anyone else. This was seconded by Mr. Robert Wakefield, president of the society, who expressed a hope that the Paxtonians might at some future time have the pleasure of another lecture from Mr. Cowan.

National Dahlia Society.—The annual report for 1899, list of members, and the schedule for the forthcoming show (all under one cover), to be held at the Crystal Palace on September 7th and 8th, have reached us from the hon. secretary, Mr. J. F. Hudson, M.A., The Gardens, Gunnersbury House, Acton. There are many classes that come year after year in the same form; but a few fresh ones have been embodied, which it is hoped will increase the interest and beauty of the exhibition. Several of these stipulate for the addition of Dahlia foliage, while in another case a silver cup is offered for nine Dahlias, distinct varieties, in pots not exceeding 10 inches in diameter. This prize is offered by F. W. Fellowes, Esq. Then we find the sum of £6 allocated to a class for Cactus Dahlias, twelve varieties, six blooms of each, to be arranged with any suitable foliage in vases, which will be provided by the society. The stems may be stiffened with wires, but no wire frames may be used. The quality of the blooms will be the first consideration with the judges. In addition to the classes scheduled, a new one has to be formed for Fancy Dahlias, for which 2 guineas are offered by the Duchess of Sutherland, who is a patroness of the Society.

Shropshire Horticultural Society.—There is no provincial society in the country whose schedule is more eagerly anticipated than that of the Shrewsbury Floral Fête, which will this year take place on August 22nd and 23rd. The committee has made a reputation for inaugurating new classes, each of which is in its way an advance on its predecessors, and we need not remind our readers of the climax that was attained to last year, when £100 were offered in one class for Grapes. This does not appear this season. We have, however, the gold medal of the society and £25 as the premier award for twenty-four dishes of British grown fruits, the remaining three prizes being of the respective values of £20, £15, and £10. This will be judged by points, the standard values being given, as also are the fruits that may be chosen. Exhibitors are informed that the "highest cultural merit is sought, and that each dish will be judged by this standard." Special awards of £3, £2, and £1 are offered for decorative arrangements, irrespective of fruit. The prizes offered for fruits will be awarded strictly for fruit only. This should make a splendid class. To refer to all the others would be an impossibility, and intending exhibitors will do well to make early application to Messrs. Adnitt and Naunton, Shrewsbury, who fortunately continue to hold the post of honorary secretaries.

Weather in Dublin.—The advent of March has brought blessings in the form of days suitable for outdoor work, as the weather has been, on the whole, dry with occasional keen winds. The season will, however, be rather late owing to the exceptionally severe weather we have experienced. In many places the Potato planting has only just begun, and similarly with other vegetables.

Sunderland Weather.—Your correspondent "S. E.," on page 212, says "the winter has not perhaps been typical; frosts have not been frequent and severe." Such, however, has not been our experience. From November 1st to March 1st inclusive we have had seventy-six nights on which the thermometer has fallen to 32° or under, the lowest reading being 10°, while yesterday morning, March 28th, the minimum register was 7°.—C. PORTSMOUTH, *Herrington Hall, Sunderland.*

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

A dull cold week, with brief intervals of bright sunshine.

The New Chiswick.

It is possible to imagine what would have been the nature of the confusion worse confounded of opinion and desire in relation to the site of the new Chiswick, had the R.H.S. Council submitted the matter to a plebiscite of the Fellows. Happily we have been saved from that calamity, to which the confusion of tongues at the Babel Tower would have been a triviality. Whenever it is announced that a public site has been fixed upon and has been practically purchased no doubt there will be a tremendous outcry. But it is absolutely certain that the new Chiswick can be in one place only, and wherever it is there is not the least probability that it will be so convenient for all anxious to visit it as the old Chiswick is.

But if, as indeed it must be, some distance from London, it may be found charmingly situated in a lovely country, where with soil of the best and plenty of pure clear air, and sunshine as well as a shelter, a really ideal garden may be furnished. Then what a delight as a day's outing will it be to visit such a garden; and besides seeing all it will have to show, to enjoy the pure air and lovely scenery, constituting in the matter of a visit a most enjoyable holiday. It would be difficult indeed to extract so much from the present Chiswick. If too, as is hoped, the Council can obtain for the Fellows special advantages in the matter of transit, how much will be gained.

Wherever the garden may be, it is certain that some time must elapse ere it can be made decoratively attractive, although that must be a minor object. As to how far it may be wisely or other-wisely associated with a national school of horticulture, sustained by numerous County Councils, time will show. But having called so long and often for such a national school, we must not now be too captious.—A. D.

Judges and Judging.

"AN Inquisitor" (page 179) of our Journal has given us "a hard nut to crack," for it opens up what we may call the whole ethics of the showing of garden produce and the equity and justice of the awards that that produce receives at the hands of those appointed to assess its merits. No doubt a considerable number of communications from well qualified writers will be received; some affirmative, some negative, some commendatory, others condemnatory.

I do not know whether I can help much in the matter; nevertheless, I will try to do my best. Let us put the question propounded by "AN Inquisitor" again plainly before us. "Should the same judges be employed year after year in the same classes at the same show?" Well, my acquaintance with shows, judges and judging is not so extensive as some people's, notwithstanding that I have done a little judging and know a few judges, and, differing from the conclusions of "AN Inquisitor," I unhesitatingly give an affirmative reply to his query, assuming, of course, and this is not an unreasonable assumption, that the right men have been selected in the first instance. By right men I must be understood to mean, good, capable, practical, all round, or specially gifted men; men of broad minds, sound common sense, and high ideals.

A judge is born, not made. A man may be a very good gardener, but a very poor and incapable judge. I suppose we shall be all agreed that he should have an intimate practical knowledge of the subjects he is appointed to adjudicate upon, their highest possible developments, with the difficulties of attaining those developments, and what we may describe as an historical acquaintance with them in their past and present state. In addition to these elementary but highly necessary qualifications, he must have a quick observant eye, a clear head to balance merits and demerits, a calm but ready decision, with authoritative pronouncement of verdict, and the power of dismissing it absolutely and passing on to the next exhibit. I have known many judges with all these qualifications. One thing is quite certain, that a vacillating minded judge is a terror to his colleagues and a failure as to equitable decisions.

Given these qualifications on a staff of judges societies would, so I contend, make a mistake—a grievous mistake—who changed their judges for the mere sake of changing or from a fancied idea that they ought to change.

I believe it to be a fact that most large horticultural societies have some person of high standing in the gardening world who has a

thorough and intimate acquaintance with gardening and gardeners, and all the leading men in the profession, on whose judgment they rely in the nominating and appointing of their judges; and I say again, when such society has a staff of judges so specially selected, each man or set of men the best in their respective spheres of action, it would be the highest folly to change. These men, the properly selected men, by being thrown together year by year, find out each other's line of thought and judgment. They learn to give and take, to see from each other's standpoint, and having those other essential qualities of openmindedness and tolerance of other men's opinions, they blend together, the work goes on smoothly, and the result is fairness and justice all round.

Now, much change, and particularly indiscriminate change, would inevitably breed confusion; would perhaps throw two men together whose points of view would be the opposite of one another, and if they happened to be obstinately opinionated, as men of strong views often are, their work would be uncomfortably done, and their decisions more or less, often more than less, would be uncertain, unsound, disproportionate, and unsatisfactory.

I say this would be the result as it appears to me, and if so nothing could be more fatal to the well-being of any society than this. Exhibitors would be annoyed, much indignant language would be used by them, the secretaries and other officers made irritable and unhappy, and specially so if the indignant exhibitors should go on to say that they had, in face of such judgment as that, determined never to show there again. I can quite understand that a certain section of judges working long together might get into a fossilised state in their judgments by reason of unitedly going along one line of decisions, but this could not often be the case, because death, sickness, and other life changes do break up the staff in a slight degree most years, and this is all the change that I, for one, should look favourably upon.

Doubtless there may be those who, like "Inquisitor," think differently, and we shall all be glad to hear them, for the subject is one well worthy of discussion, but the above are the thoughts and opinions of — AN OLD PROVINCIAL.

Stopping and Shortening Vines.

For the sake of clearness let it be said that "stopping" has reference to removing the tips of the leading, as well as the axillary, growths of young Vines when in an active state, and that "shortening" applies to cutting back the canes when resting after their season's growth.

A correspondent, "A. J.," described generally excellent practice on page 182, March 1st. Mr. E. Molyneux (page 199) rather questions the soundness of that practice, and submits what he conceives to be an improvement on it. Possibly it may be, though I am not confident it would be as carried out by all growers of Vines, and at least I am of opinion that "A. J." did not "commit" any serious "error" in his routine.

It is due to Mr. Molyneux to say that he is the exact reverse of a carping critic. When he differs from any published statement he almost invariably propounds some practical alternative to the procedure previously advocated. This is entirely commendable, but it does not conclusively prove the existence of an error of such a nature that may be likely to lead many readers astray.

Mr. Molyneux's method of shortening the canes of resting Vines to within two eyes of the base is excellent, always provided this is done at least two months before planting, and also when the fullest light can reach the cut-backs in the position in which they are planted. In not a few vineries the front wall is raised considerably above the border, and in several a flat stage runs along about level with the front sashes, and over from two to four rows of hot-water pipes. This may not be the best arrangement, and is not advocated; but it exists, and to plant such close cut-backs in such positions inside the house would be as bad as the wall and pipe arrangement, if not worse. In all cases of the nature indicated an extension of cane must be allowed to bring the two uppermost buds to what may be termed the light line to insure a strong growth to form the future Vine. The distance between the ground and light line should always be measured where the young Vines intended for planting are shortened. Grand Vines and crops of Grapes have been produced when the planting canes had to be left 3 feet in length.

Even under favourable conditions—i.e., when the border was little below the level of the front sill—entirely satisfactory results have followed the plan of shortening to about 18 inches, and when the lower bud is allowed to extend to develop half a dozen leaves or so, as advised by "A. J.," the base of the stem thickens satisfactorily, as it would, of course, under Mr. Molyneux's plan, in a natural way. There are circumstances in which either of the methods may be better than the other, and neither of them, in the absence of essential qualifications, can be justly described as erroneous. Something might, perhaps, be advantageously said on summer stopping, but this must await a more favourable moment.—AN OLD EXHIBITOR.

The Renovation of Old Fruit Trees.

(Concluded from page 196.)

I HAVE given in detail that part of the process of renovation which applies to the stem and branches of the tree. The work does not, however, stop here. A healthy and successful growth of the tree above ground is only to be obtained in conjunction with an equally healthy life underground. The development of a tree is always limited by the existing conditions of its root development, and therefore the nourishment of this portion of the organism, at all times exceedingly important, becomes considerably more so in the case of old trees such as I am describing. For it is obvious that with aged trees, as with aged persons, greater care must be bestowed on the channels of vitality if energy is to be preserved.

The need for special attention to the roots of these old trees is this:—A different kind of growth has to be encouraged; a growth which shall be more fibrous and nearer the surface than that which already exists—fibrous, for the better reception of plant food; nearer the surface, that this food may be the more easily supplied. In the case of trees planted in the kitchen garden, fork the surface soil over lightly from time to time, and in the autumn put on a good top-dressing of farmyard manure, which shall be allowed to remain throughout the winter to the spring, by which time the goodness will have been washed into the soil. Then fork over lightly again, add a sprinkling of some good fertiliser, and work well into the soil. If dry weather sets in, mulch again with farmyard manure and moisten as often as is necessary with plain water or with what is much better if it is available, liquid manure from the farmyard. In this way surface roots are encouraged.

It may also be added that a top-dressing of soot has a tendency to bring the roots upwards. Having done this, never allow a spade to be used near the trees. If they are found to be making too much wood and leaf without fruit (which is rarely the case with old trees), withhold the manure, but continue the mulching throughout the summer with any light material that may be available to prevent the roots being damaged by the heat. If the trees are planted on grass, encourage the surface roots as much as possible by top-dressing with farmyard manure, and, if the weather is dry, use plenty of liquid manure. Do not, however, allow the trees to get too dry before the watering is commenced, as it is very difficult to get the water to soak down when the ground is too dry.

I have only lightly touched on pruning, but this is one of the most important points to be observed in the renovation of old fruit trees. This must be done on somewhat similar lines to those adopted in dealing with a young newly planted bush tree until the head is formed. There is often a large amount of vitality in an old tree, and when it is cut back the young growths are much stronger than in newly planted ones, and as a matter of fact there is more leafage. Now, this pruning and regulating the growths have a most marked effect on the root action of the tree. It seems that there is a large

store of potential energy which is ready to come into action as soon as the trees are cut back, for the root and top act simultaneously.

All the weak spindly growths must be cut clean away, and also such of the stronger ones as are not required to form a symmetrical head. If too much is left a thicket of wood is formed which is fit only for the birds to build in. Good, well-coloured fruit can never be obtained under such circumstances. Therefore, regulate the young growths, in order that sun and air may have full play on every leaf and bud. It will be necessary to shorten the growths, but they must be shortened back to good, well ripened wood. That is absolutely necessary, not only to encourage more active root action, but also stronger wood and larger leaves.

The probability is that unless the new growths are cut back to well matured wood the leaf will not be more than half the size and

substance it should be. The larger and healthier the leaf the more fully will the fruit bud be developed, and without a well developed fruit bud it is impossible to get fruit. It is obvious that judicious pruning is of the utmost importance, and should go on from year to year. Thousands of trees are left entirely to chance, or so carelessly pruned that a crop of presentable fruit becomes almost impossible. But with treatment such as I have described a splendid tree will be obtained in three or four years, which will well repay the labour bestowed upon it.

What has already been said concerning Apple trees applies equally to Pear and other fruit trees. The great objects are to secure fibrous and superficial root formation underground, and clean, healthy, vigorous growths from the stem. We have lately been passing through a series of very dry summers, that have proved detrimental to the free growths on old trees. Hence the necessity of paying a little extra attention in the way of watering, mulching, and feeding in order to assist the growths as much as possible.

It may not be out of place to deal very briefly with the insect pests as they affect old trees. It is of the greatest importance for the well being of the trees that they should be kept clean. Scraping off some of the old dead bark will do no harm, provided it is done with care,

so as not to interfere with the inner skin. As with old Vines, the scraping must be done judiciously, and not too hard. Wash the stems with a rather strong solution of softsoap and water; this will kill most insects found lurking under the old bark; then apply a dressing of soot and lime of the consistency of thick paint, which will to some extent prevent the insects from depositing their eggs on the stem.

I should like in conclusion to touch very slightly on two other points. The first is with regard to gathering the fruit. Unless some care is exercised a large number of buds are destroyed. After trees have been subjected to the renovating process for a few years, they naturally have a quantity of spurs which bring fruit, and it often happens that through careless gathering, the bud for the following year's fruit is destroyed.

The second point is also connected with fruit harvesting; it is—the preservation of the leaf—for this has an important bearing upon the full development of the following year's fruit bud. If we observe the course of Nature, we shall know that the fall of the leaf takes place considerably after the time of gathering the fruit, and when one sees

FIG. 66.—PEDESTAL STAND OF FOLIAGE PLANTS.

the ground covered with leaves which have been carelessly plucked off at picking time, it is evident that the tree has been partially denuded of its clothing before the proper time. Therefore, in picking, endeavour to preserve both buds and leaves for the sake of another season's crop.—(Paper read before the Reading Gardeners' Association by MR. T. NEVE, Sindlesham.)

A Few Hints on House Decoration.

MODERN decorative work has undoubtedly been developed into a fine art, and to carry it out successfully the artist must take into consideration the size and form of halls or rooms to be embellished, and so arrange the material at command as to give a due sense of proportion between prominent plants or groups, and the rooms in which they are disposed. In a large lofty hall it is quite impossible to secure such desirable results without the aid of fine bold Palms, or some means of elevating smaller ones to the required height. Pedestals surmounted by large massive vases are just the things required to help the decorator out of such difficulties, and for that reason I trust the accompanying illustration (fig. 66) will prove both interesting and useful to readers of the *Journal of Horticulture*, and not unworthy to adorn the pages of so prominent a periodical. When, as in the case of the illustration, the pedestals are of marble, their great weight keeps them firmly in position, no matter how heavily laden the vase may be; when, however, pedestals of lighter material are used there should be some means of securing them to the floor, or to a larger base, or accidents will occur.

The arrangement given is formed entirely of foliage plants and Ferns, without the addition of a single flower; but by paying due regard to that point which is so necessary in decorative work—viz., variety of form in those materials employed—the effect produced is bold, striking, and interesting to note in detail. The central plant is a rather tall one of *Dracæna Veitchii*; beneath it are a few plants of *Cocos plumosa* and *Kentias*, with *Aspidistras*, Ferns, and *Smilax* to complete the arrangement. Some of the smaller plants are turned out of their pots, and all are packed firmly in moss, yet the foliage is abundant enough to completely hide the moss. For special occasions, should the group need lightening with flowers, these can be used in a cut state, by fixing them in tin tubes of various lengths, and thrusting the tubes into the moss. A much better effect can be secured by using flowers in the above way than by relying on plants growing in pots.

The position of the pedestal is also worth noting, as it is placed at the corner of a massive table, where something seems to be required to give relief and tower upward in the lofty hall in which the pedestal

stands. A couple of such pedestals and a few tall *Kentias* or *Chamaerops*, with masses of flowers beneath, would convert into a perfect fairyland many stately halls in the great homes of England which at present lack such striking features, although they are really as necessary as suitable furniture when the object is to secure a fine effect.

When arranging cut flowers one generally has to make the best of whatever vases are at command, but these are sometimes by no means well adapted for displaying flowers to advantage, and the light and pretty effect so necessary is then difficult to secure. When rather tall arrangements are required for placing in prominent positions, large trumpet-shaped vases are generally used, and although they are quite suitable for such purposes, it is, I think, wise to sometimes have flower stands of different forms for the sake of variety.

Some which are placed on the market are exceedingly well designed, and enable a good decorator to produce delightful arrangements with comparatively few materials. Fig. 67 illustrates a French Bamboo flower stand dressed with flowers and foliage. These can be obtained in sizes ranging from 13 inches to 6 feet. In the top of the Bamboos tubes for holding water are inserted; there are generally two tiers of tubes. The flowers employed in the arrangement depicted are Callas, Daffodils, a long spike of *Odontoglossum*, and a few other Orchids. Long shoots of *Cyperus alternifolius*, fronds of *Adiantum formosum*, *A. concinnum*, *Phlebodium aureum*, and Daffodil leaves supply suitable greenery, and a few trails of *Smilax* and *Ivy* give a light draping to the base of the stand. Occasionally we hear a "wail" in the horticultural Press in regard to the alleged artificiality of flower arrangements, and the writers bemoan the fact that flowers are not more often associated solely with their own foliage. I fear their criticisms will not alter present methods, for the simple reason that a lighter and better effect

FIG. 67.—BAMBOO STAND OF FLOWERS AND FOLIAGE.

is invariably obtained when green and other foliage are associated with flowers, as well as some of their own leaves.

To illustrate my point let us take as an example fig. 67. In that arrangement if I had adhered to the practice the critics think correct, the only foliage used would have been a few Orchid, Daffodil, and Calla leaves, the lightness in the arrangement illustrated could not then have been secured, and the interesting variety in the form of the foliage, which helps so much to make a distinctive photograph, would have been absent, and I think much needed. By all means let us, when possible, arrange flowers with some of their own foliage, but whenever the correct taste—which comes with experience—shows that the addition of foreign greenery gives a more charming effect, let not the critics deter us from giving that artistic touch which will command instinctive admiration.—H. D.

Rose Show Fixtures in 1900.

- June 27th (Wednesday).—Salisbury (N.R.S.) and Richmond (Surrey).*
- „ 28th (Thursday).—Canterbury.
- „ 30th (Saturday).—Windsor.
- July 3rd (Tuesday).—Westminster (R.H.S.), Gloucester, Harrow and Sutton.
- „ 4th (Wednesday).—Croydon, Hereford and Reigate.
- „ 5th (Thursday).—Bath and Norwich.
- „ 7th (Saturday).—Crystal Palace (N.R.S.).
- „ 10th (Tuesday).—Wolverhampton.†
- „ 12th (Thursday).—Brentwood, Eltham and Salterhebble.
- „ 18th (Wednesday).—Cardiff.*
- „ 19th (Thursday).—Birmingham (N.R.S.) and Helensburgh.
- „ 24th (Tuesday).—Tibshelf.

* Shows lasting two days. † Show lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear early in April.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Banksian Roses.

THE Banksian Rose does not flower freely in a clay soil unless the plant has a very warm position. The flowers are produced on small hard twiggy growths, which should not be shortened; a close pruning is unsuitable. Gross growths ought to be removed towards the end of summer, so as to admit the sun and air to the smaller shoots, and these, if matured and not shortened will produce flowers. What must be sought for are numbers of rather weak growths, and these must be matured by full exposure to the sun.—ROSARIAN.

Marechal Niel for Profit.

PROBABLY no Rose is more profitable than *Maréchal Niel* when it is successfully grown, as fine blooms of it are always in demand, and usually fetch a good price. But against the profits must be set the time—two, or even three, years—that it takes to get the plants into a healthy state, so that a regular supply of flowers in season can be depended upon. Provided the plants are in proper condition, however, there is no doubt that a house or two of *Maréchal Niels* pay, and pay well.

The method adopted in most places where this Rose is grown to pay is as follows:—The house, or houses, to be planted is usually span-roofed, about 10 or 12 feet high, and 15 to 20 feet wide, with a single path down the middle. (A house suitable for a vinery would do equally well for *Maréchal Niels*.) The whole of the floor space, with the exception of the path, is used as a bed for the plants, and is trenched 3 feet deep, turning out any cold or heavy soil that may be encountered, and at the same time seeing that the border is well drained. While this is being done, sharp sand and manure are worked in with what is kept, the aim being to make the soil lighter and more porous than is usual for Roses. Leaf mould is not much in favour for these borders, as it is liable to breed a fungoid growth which rots the roots.

The borders are sometimes raised if the ground is very heavy and wet, but this is only done when absolutely necessary, as it entails a considerable amount of labour. The plants used are two-year-old, worked on the Briar, and are planted 6 feet apart on either side alternately, near the side walls, so that they can have a straight run up the wires, which are 15 or 18 inches from the glass to allow room for long-stemmed flowers to develop. At the time of planting the Roses usually have one or two stems about 6 or 8 feet long, which are cut back before they break to within two or three buds of the base. When they commence to grow the shoots are all removed except two or three of the strongest, which are encouraged to progress in every way.

During the summer the syringe is freely used in sunny weather two or three times a day, and the floor is kept moist. Water is also generously applied to the roots, liquid manure being used on each alternate watering, with an occasional top-dressing of artificial manure. The temperature is kept fairly high during the early summer to induce free growth, but as the year advances more air is gradually given, until in the autumn the house is left with full ventilation on day and night to thoroughly ripen the wood.

Through the winter air is left on unless very severe frosts ensue, when the house is closed and a little fire heat utilised to keep the temperature from going much below freezing point, though a few

degrees of frost do not hurt the plants. In the spring the plants are cut back to the lowest wire, when disbudding is again practised after they start, and six or eight of the best shoots left, which are trained up the wires at a distance of about 6 inches from each other, the temperature during the summer being the same as in the previous year. These shoots at the end of the summer are from 15 to 20 feet long, and the following spring are allowed to flower.

The first two years being safely got over, the culture afterwards is simple, the growths being cut back annually immediately after flowering to within two or three buds of the base, and the resultant shoots disbudded, leaving only sufficient to fill the wires, and keeping these tied regularly so that they do not grow into a confused mass. Plenty of syringing, watering, and feeding during the summer, and changing the manure frequently, will produce growths that will flower at every joint for nearly their whole length. As many as fifty-two flowers and buds have been counted on a single shoot; and that has only been one of many.—C.

Zonal Pelargoniums for Winter.

“GERANIUMS” (Zonal Pelargoniums) play an important part in the decoration of the greenhouse during the winter months. The simple treatment they require to insure a good display of bloom has won for them a leading position amongst greenhouse flowering plants. Some varieties are much better for winter blooming than others, and I have proved them to produce flowers freely from October to February.

Cuttings should be taken forthwith and inserted singly in thumb pots. I prefer this plan to placing three or four in larger pots, as the plants when rooted can be shifted into larger pots without experiencing any check whatever. A soil composed of loam, leaf soil, and sand in equal parts will answer. After the cuttings are inserted give the pots a thorough watering through a fine-rose can to settle the soil about the base of the cuttings. A vinery “at work” will be an excellent place to root them in; failing this, a warm greenhouse will answer the purpose, although they will be a little longer in emitting roots there. Their first shift from the cutting pot is into 3 or 4-inch, using a compost of two parts loam and one each of leaf soil and spent manure from an old Mushroom bed. The plants should then be assigned a position near the glass until well established, when, if the weather is favourable, they may be transferred to a cold frame.

From that time onward they should be continually stopped, and the flower buds nipped off as they appear. Five or 6-inch pots ought to be used for their final shift, and should be well drained to prevent stagnation at the roots. A plan I have found to answer well is to place a layer of half-inch bones over the crocks; the roots permeate these, and derive a considerable amount of benefit therefrom at the flowering season. The soil should be pressed down moderately firmly, carefully avoiding filling the pots too full, a good half-inch of space at the top being necessary for watering the plants. As soon as they are well established in the flowering pots, which ought to be by the first week in June, the lights should be entirely removed if fine weather prevails; if the reverse, they must remain on until it is more favourable. The object is to give them as much air as possible without exposing them to too much wet, which would prove of the greatest detriment at that particular time. The pots should stand on a good layer of coal ashes to allow of free drainage underneath.

By the middle of September they must be housed, affording a light airy place in the greenhouse. Stopping the plants may now be discontinued, as also the disbudding, but if extra large trusses of bloom are preferred to a greater number of smaller ones, the points of the shoots should be again nipped out one joint above the flower. This ought to be performed while the flower bud is in a small state, thus concentrating the whole energy of the plant on the perfecting of the blooms. At that stage they will be much benefited by occasional applications of liquid manure, that made from cow’s or sheep’s manure being preferable. Artificial manure is better left till a later period when the soil has become somewhat impoverished; a sprinkling then will renovate and instil new life into the plants. The number of well proved kinds of artificial manure make it a difficult matter to select any particular one as the best. I used to give the preference to Standen’s, but latterly I have found that Thomson’s Vine and plant manure and Clay’s fertilizer give equally good results.

Occasionally the plants suffer from the attacks of a green caterpillar, which if not attacked commits sad havoc amongst the leaves. Owing to their colour the caterpillars are difficult to see, but a sharp shake of the plant will generally dislodge them. Watering must receive great attention, especially at the time when the plants are first housed. My experience is that they often receive too little at that time, the prevailing idea being that they should be kept on the dry side. These conditions, however, will be better observed a month later when the sun has diminished in power; meanwhile if the weather prove bright, a sprinkling with the syringe in the afternoon will prevent loss of foliage and accustom them to their new conditions.—L. J.

The Loquat.—Though a second rate fruit even at its best, and this is not often seen, the Loquat is a useful plant where large conservatories and halls have to be furnished. Seedling plants are best for this purpose, and if not grown too rapidly they are useful for seven or eight years in the different sizes. A fairly stiff loamy soil should be given, this being rammed in very firmly. Give small shifts, and keep the foliage clean by occasional syringing. Should thrips appear they must be at once got rid of by fumigating, or the appearance of the plants is spoilt.—H.

Kennedya prostrata.—Of the many beautiful New Holland plants at one time so popular in English gardens few are now cultivated to any great extent. The plant under notice was introduced upwards of a century ago, and, though rarely seen, is one that might be cultivated largely for a variety of purposes. It is of semi-woody habit, making prostrate growths 3 feet or more long, with small, ternate leaves; the wood and leaves being thickly covered with fine soft hairs. The Pea-shaped flowers are scarlet, with a yellow blotch at the base of the upper petal, and are 1 inch across. They are usually produced in pairs from each node all along the shoots, the flowering period being from February to May. Seeds are the best means of propagation, and equal parts of peat and loam, with a good quantity of sand, form a good compost for seeds and plants. It is equally at home grown as a trailing plant on a tree root, trained loosely on sticks, on a balloon, or in a hanging basket. When grown in the latter way the full beauty of the graceful shoots, flowers, and foliage is best seen and appreciated. Good sized plants can be had in twelve months from seed if grown in an ordinary greenhouse.—D. K.

Early Unforced Rhubarb.—Many persons would fail to realise what an advance may be gained in time of pulling outdoor Rhubarb by the simple use of strawy litter as a covering to the crowns. At the present time, March 14th, I am able to gather short stalks, though a supply indoors does not render this necessary. From this outdoor supply comes much better quality both in crispness and flavour than forced roots furnish. Considering how cold and sunless the season has been so far, it is not a little remarkable that activity can be set up by the simple use of strawy litter as a covering so early. This is not put on until February, for it is better that the winter's frost should be allowed to exercise its influence on the crowns to insure complete rest. Although the early sorts naturally give the quicker supply, it is surprising how it advances late varieties like Victoria. Material fresh from the stable, with the short shaken out of it, is what I use, and as this becomes washed with rain, and sweetened by air and frost, there is no taint given to the stalks by the time they rise upwards through it. It is necessary to raise this as the leaves develop, and shake it lightly over them occasionally, so as to protect them completely from sudden frosts, which so often occur at this time of year.—R. A.

Winter Spinach Failing.—The culture of Spinach as a winter crop is fraught with occasional disappointments brought about mainly by the influence of the weather—autumn and winter. Last autumn was by no means a favourable one, for in many places, unless daily watering could be carried on, it was impossible to get the seeds to germinate. Often, too, when such a state of weather is followed by an excess of rain, disease becomes very rife among the plants, and the supply is reduced to a minimum. This is what has happened this winter, and the scarcity of other vegetables made it the more keenly felt. A reserve crop, however, of the useful Spinach, or Perpetual Beet, has once more justified its sowing, and proved a good substitute. April or May are suitable months for sowing. Once established all that is needed is to keep the soil free from weeds by hoeing. By reason of the continuous rain and snow, no seeds of the ordinary summer Spinach could be sown outdoors until the first week of March, and in heavy soils not even so soon as this. The present month for the first ten days was dry, and by lightly forking over the surface, the action of drying winds had a marked influence for good, and allowed of sowing several days earlier than would have been possible if the ground was left unmoved.—S., Wilts.

Damping Off.—This term is applied to the leaves, flowers, or stems of plants. Its effects are most marked on young and tender seedlings when crowded together, or placed under unsuitable atmospheric conditions. It is caused by a fungus, and is usually traceable to an excess of moisture that may be suspended in the air or applied to the roots. Damping off amongst cuttings is often caused by allowing them to become dry, and then suddenly applying too much water. A temperature in a glass house or propagating frame lower than that outside very often gives rise to "damping." Immediately damping is detected amongst tender seedlings, says a contemporary, they should be separated and placed out singly in fresh soil. This will invariably check it, but the operation is best performed before damping begins.

Aphelandra aurantiaca Roezli.—A group or two of this brightly coloured Mexican plant make a charming addition to the stove in winter and early spring, besides being an admirable plant for house decoration where dwarf plants are required. The flowers are tubular, $1\frac{1}{2}$ inch long and $\frac{3}{4}$ to 1 inch across the mouth, about thirty flowers constituting an average raceme. Although plants may be grown for several years it is preferable to raise a new stock each year from cuttings. These should be inserted in sandy soil in March or April, and plunged in a case with a brisk bottom heat. After they are well rooted they should be potted into 3-inch pots in a mixture of loam, peat, and sand; afterwards they ought to be moved into 5-inch pots in which they should flower. Arranged with foliage plants the brilliant flowers are particularly pleasing, coming at a time when bright coloured flowers are usually scarce.—D.

Ferns in New Zealand.—In a place that was formerly all forest, but which is now more or less cleared, there are on the high ground acres of *Pteris scaberula*, a most beautiful Fern; *Lomaria discolor* is in plenty, and grand, as are many other Ferns. At the bottom of the valley is a good stream, and along its banks are charming Ferns. Where the cliffs, overhung with scrub, are close to the brink, *Todea intermedia* hangs in all its beauty, *Lomaria fluviatilis*, *L. filiformis*, *Pteris macleteria*, *P. incisa*, *Asplenium bulbiferum*, *falcatum*, *flaccidum* and *obtusatum*, and *Polypodiums luxuriate*. Grand specimens of *Dicksonias squarrosa* and *antarctica*, *Hemitelia Smithi*, and *Cyatheas* are frequently met. Ferns have often lured me to the bush, and in my own immediate neighbourhood, within an hour's walk, I can find about forty species, some more plentiful than people used to be on Clapham Common on Derby Day, and others just the reverse. I propose to write again, as I want to try if I can send some *Adiantum* fronds for identification. I have one plant which was quite small five years ago, and is now 6 feet through, without any tying out, and nearly 5 feet high, the actual fronds, rachis, and all being about 40 inches long.—W. H. TAYLOR, Wellington, N.Z.

Birds and Crocuses.—I was invited the other day by a neighbour to explain how it was that sparrows destroyed yellow flowered Crocuses only, and did not touch those of other colours. My neighbour thought the birds were offended by the glaring hue of the yellow Crocuses. I prefer to think that the birds do not pick off the flowers wantonly, but do so because they find in them some secretion that is sweet, and of which other coloured Crocuses are deficient. But it would be very interesting to be able to learn from any source, if such information can be given, what is the real cause of the damage thus done to these flowers. I take it that their action in relation to Crocuses and Primroses or Polyanthus is ruled by the same object or motive. No doubt we shall find some correspondents writing to say that with them the sparrows destroy *Crocus* flowers of all colours. Certainly with Primroses and Polyanthus they are no respecters of colours. When looking over the huge breadths of variously coloured Crocuses on the grass at Hampton Court just recently—and there are tens of thousands of them, extending over a very large area, and constituting a most beautiful display, far excelling in effect anything obtained from beds or lines in borders—I noticed that there was a large number of yellow flowers, but no evidence of harm having been done to them there, perhaps because that portion of the garden is so largely frequented. But in the more private enclosure of the inner gardens, where there is much tree and shrub shelter, many flowers of yellow Crocuses had been picked off; but then there were yellows only in this position. Whatever may be given as the reason, it must be a practical one. To suggest that the mischief is a purely wanton act will not do. Birds generally have a reason for what they do, and I can only think that sparrows find in the *Crocus* flowers something which they like.—A. D.

Cinerarias.

It is generally acknowledged that at this period of the year Cinerarias are amongst our most useful and effective decorative plants, especially if the varieties are of good self colours. Pretty as a mass of mixed colours may be, I think that a group of selfs, in colour, such as reds, whites, and blues on the conservatory floor forms a sight not easily surpassed. There seems to be an idea that the Cineraria is not so well grown now as in the past, and I think we may admit that we do not usually meet with such fine individual specimens as was the case twenty or twenty-five years ago, owing doubtless, in part at least, to its liability to attacks of green fly.

I think, however, the chief reason is found in the change time has brought about; the requirements of those days were vastly different from what are expected at the present. Some years ago the finest specimens for conservatory decorations seem to be preferred; to-day we must have small plants suitable alike for house or conservatory decoration. This is the general rule, whether we look at the matter from a private or commercial point of view.

This, then, does not encourage the assumption that the Cineraria is not so well grown now as in the past; on the contrary, I think that time has done much to improve it. Certainly there is no comparison in the size, the colour, the form, and general quality of the flowers of to-day, and notwithstanding the introduction of various other acceptable plants during recent years, it is still a favourite, and as indispensable as ever. Not only is this the case in our private places, but as a plant of commerce, for we gather that the Cineraria is most extensively grown for the supply of the metropolis and large midland towns, where it is in great demand by those whose lot does not admit of their enjoying the beauties that are so common to ourselves.

It is generally considered that the Cineraria is of easy culture provided the conditions essential to the plants' well-being are always kept in mind. The first point is how to secure a really good display of bloom, and this can only be done, if seeds are relied upon, by procuring the best strains possible. The time of sowing must be governed by individual requirements. Where two or three separate collections are grown a good time to commence would be about the middle of March, with successional sowings in May and July; these would give flowers from November to the end of May. The first consideration must be the raising of the young plants. There are two methods—namely, the sowing of seeds, and propagation by cuttings. The former is the more general, but the latter is the better for certain purposes, because we cannot depend upon getting a particularly good variety true from seed.

Of course we must have, as I said before, seedlings from an excellent strain, to get high class flowers. A good means of obtaining the choicest varieties is to select a plant producing the finest flowers and of a good habit of growth to propagate from. By this system one can collect in a couple of seasons a very fine stock. I usually sow a number of seeds about the middle of May, but, as I have before stated, one must be guided by one's own requirements. The pans should be filled to within an inch or so of the rim, using a compost of loam, leaf mould, and sand in about equal parts, the whole being run through a sieve; make the surface fairly firm and level, and then give a thorough watering through a fine-rosed can. Let the pan stand for a time before sowing the seeds, then scatter them thinly and evenly over the surface, and finish with a thin covering of sand. I am aware other methods are adopted in raising Cineraria seeds, some growers preferring to cover the seed lightly with sphagnum moss; others again use no covering, simply keeping the seeds perfectly dark until they have germinated, then gradually bringing them to the light.

After covering the pan with a sheet of glass, it may be placed at the foot of a north wall or hedge, under a hand-light or frame, or wherever there may be available space; they should be kept close to prevent evaporation, as I believe in the vast majority of cases want of moisture is the cause of failure in the germination of Cinerarias, as well as many other small seeds we grow under glass. If, however, the frame be kept closed, as advised, and a good soaking given in the first place, this will be found sufficient until the young plants appear. Do not allow the sun to shine on the glass, and it is also well to raise the pan, to prevent slugs from eating the tiny leaves as soon as they appear, at which stage remove the glass. If the advice of sowing thinly be followed, nothing need be done until the first rough leaves are formed; they should then be carefully raised out of the earth and placed singly either in small pots, or again be placed back into pans or boxes, using similar soil.

Here occurs to me that many of us in our desire to secure what we think a good stock are apt to take the quantity and leave the quality, or in other words, we take the stronger seedlings and leave the smaller, which in many cases are the cream, as regards quality. It is, therefore, advisable to take every care of these weaker seedlings,

which should be pricked into pans and treated as their stronger companions. They must be kept moist by lightly sprinkling with water; also be close for a week. In a short time roots will show through to the side of the soil, and the plants may be transferred to 5-inch pots. The compost should be somewhat coarser at this potting, and must be pressed in rather firmly with the fingers to induce a sturdy growth. After a few days when the roots will have taken to the new soil, admit air freely in the frame, which should still be in a position where the sun does not beat directly upon it, or if so it must be shaded.

It is excellent practice to raise the frame on a brick at each corner. This will admit of a current of air passing among the pots, which will conduce to stronger root action, and assist in keeping the plants sturdy, which must be one of the chief objects in view. In this position the lights may be kept off during fine weather, but should be in readiness for use in the event of heavy rains or thunderstorms.

Before proceeding further I will speak of offsets. The best time to take these, if they can be had, is while the plants are in flower. In most cases suckers spring from the base, and these are what we require. Cut them off with a sharp knife, and put singly in small pots. The hand-light will be a suitable covering for them, and they must be kept moist and close as advised for seedlings. These cuttings root in a very short space of time, and as soon as this has taken place the plants may be put direct into 48-pots, and be treated in the same manner as the others.—(*Paper read by MR. W. H. DAMERELL, Underbank, at a meeting of the Torquay Gardeners' Association.*)

(To be concluded.)

Droitwich Experimental Garden.

MR. J. UDALE, F.R.H.S., sends us a report of the above experiments, as conducted by him for the Worcestershire County Council in 1899. The garden, which is 2 acres in extent, was established in 1896, and is well stocked with the different kinds of fruit, while vegetables have adequate attention in the form of comparative trials of varieties, and the effects of different manures on them. The report is an elaborate one, and evidently the work is carried out with great care, and the results systematically tabulated. The garden appears to be increasing in popularity, as there is an increase in the number of visitors from 911 in 1897 to 1809 during 1899. The soil is described as dark sandy loam, the subsoil very gravelly marl, and of a naturally dry nature. A few of the season's results may be noted.

FRUIT EXPERIMENTS.—Of the larger kinds—Apples, Pears, and Plums—the trees are obviously too young for displaying the characteristics of the varieties; but New Hawthornden, Court Pendit Plat, Lord Grosvenor, and Lane's Prince Albert appear to have made the best start in yielding; and, as might be expected, vertical cordons were the most productive form of trees. Gooseberries show how quickly some of the varieties come into profit. Whinham's Industry heads the list in productiveness, followed by Rough Green and Whitesmith, all free growers. Red Currants: La Fertile (Red Dutch) is described as the best, both in vigour and fruitfulness; Victoria the next in merit. The timely application of black cotton from branch to branch prevented injury to the buds. It is allowed to remain permanently. Among Raspberries Superlative is proving itself the best variety for all purposes. The most productive Strawberry of the season was Royal Sovereign, Countess excelling all others for flavour.

VEGETABLES.—Of these many kinds were tried, and the produce of several were sold as a test of their value. In a trial of early Potatoes Sharpe's Victor gave slightly the best yield. It was closely followed by Ringleader, the next in order of merit being Sutton's A1 and Webb's Early Ash-leaved. Windsor Castle gave the heaviest yield of the main crop varieties, followed by Ninety-fold, Supreme, and Reliance. Sets of 3 ozs. weight were found more productive than 2 oz. sets. Onions were tested as to thinning. With all the rows a foot asunder, in four out of five trials the heaviest yields were produced by thinning the plants to 2 inches apart. In the trial of spring Cabbages Early Offenham realised by sale close upon £40, Mein's No. 1 £37, and Ellam's Early £27 an acre. They were all sown on August 11th; cutting of the first-named variety commenced on April 22nd, of the second on May 20th, and of the third on May 27th.

MANURES.—With practically all crops chemical manures proved much less satisfactory than farmyard manure, also than decayed and burnt vegetable refuse, the effects of the chemicals being presumably nullified by the extremely dry season. A mixture of superphosphate, nitrate of soda and kainit, scattered in the drills when sowing the seed, had a pernicious effect, for Peasso treated were destroyed as they germinated, few plants appearing. Some of the rows were left as an object lesson of how not to apply chemicals; others were hoed up and sowing repeated without adding more of the fertilisers, satisfactory results following. The Rape meal manure "Homœo" was found excellent in promoting growth and in repelling wireworm attacks on root crops. Mr. Udale has done his work thoroughly, and his report is interesting and suggestive.

Hardy Flower Notes.

" * * Through the glades the balmy southern air,
And birds and boughs proclaim that spring is here."

THOUGH the lover of hardy flowers need not long be without a few of the objects of his care, this season has been a laggard one. Not that its lingering steps have not brought compensation, for the flowers have stayed so long in the lap of Mother Earth that when they did appear their blossoms have had a more kindly time than often falls to their lot in this climate of ours. We are enjoying, as this is written, calm days. Sunshine is not plentiful, but wind and rain are not troubling us, and tender-looking blooms stand longer in beauty.

Though the sweet winsomeness of the greater number of our spring flowers has not yet appeared, we have many of the early flowers. The "Fair Maids of February" have, many of them, waited for the coming of March ere they drooped their pure blooms from the fragile-looking stems. They are as lovely as ever, whether they come in the form of our common Snowdrop or in that noble flower *Galanthus Melvillei*. The many beautiful varieties of the Snowdrop are alluring in their beauty of form and chaste colouring of white and green; the latter exchanged in some three or four varieties for pleasing soft yellow markings. Fortunately even the earliest Snowdrop has lasted long this season.

Distinct in many ways, the Snowflake is no unworthy rival or companion to the *Galanthus*. Its large open bell-like flowers do not show much likeness to the Snowdrop, yet one finds a good many people still who think it is only a *Galanthus*. Its flowers are charming with their satiny lustre, and the beautifully marked spots on the exterior of the segments. Perhaps the best is the tall robust species, which generally gives two flowers on a stem. This is the variety *Vagneri* of Mr. Baker, though it is usually sold as *L. carpathicum* (fig. 68) by the bulb dealers. It is earlier than any of the other forms. It is unfortunate that so few know the worth of *Leucoium vernum*, the Spring Snowflake, and its varieties. Those only who claim acquaintance with the Summer Snowflake can have little idea of the superior beauty of its vernal sister, with its neater habit and larger flowers.

The fine weather since a stormy February ran its course has been extremely favourable to the Crocus. The season being late, not many of the varieties of *Crocus vernus* are in bloom as this is written, save in the sunnier spots. It is a misfortune that people know so little about the Crocuses which are not usually embraced in the lists of bulbs sold by the ordinary dealer. Without touching on the charming Crocus species, we have varieties of *Crocus vernus* which are not generally known. I have one beautiful variety in flower at present that is named *C. vernus picturatus*. The ground colour is white, exquisitely decorated on the outside of the outer segments with a charming feathering of purple. Near it I have just coming into bloom that curiously pretty form known as *George Maw*, whose white flowers have a golden stigmatic band up each segment. Then there is the very pretty variety of the same species called *leucorhyncus*, whose white flowers are so distinctly feathered with purple. It bears the popular name of "Pheasant's Feather Crocus."

Crocus biflorus, too, yields us some pretty flowers. I am never tired of looking upon the typical form, whose white flowers with their yellow zone peep from among the grassy leaves. There are, however, varieties of great beauty, though a little higher in price, which are worth looking out for. There is the exquisite little gem named *Pestalozzoe*, whose small and shapely white flowers look so charming in the rock garden at the present time. The variety *Weldeni* is also very fine with its pretty blue markings on the outside of the segments. I have on the table before me a variety of *Weldeni* that was sent me by a Crocus-loving friend in the south. The marking on the outside is much deeper than usual, and one longs to possess so pretty a form. One could say much more of that flower which now enamels the ground with almost all colours, from white to purple and from pale yellow to orange with many lovely markings. Space forbids, and other flowers must have their due.

We catch here and there a glimpse of blue and white, purple and pink, from the flowers of the *Hepaticas*. They are charming where they are at home, and I often wonder that those who have time do not raise seedlings from their own flowers. It is interesting work, holding forth always the hope of something new.

Charming flowers are those hardy *Cyclamens* nestling under the rockwork's semi-shade. They are *Cyclamen Coum* and three of its varieties. Their beauties are incontestable, though there are some who worship the fetish of size who look at them a little disdainfully because, forsooth, their blooms are not so large as those of *Cyclamen persicum*. This is quite true, but then the latter needs not only glass to shelter it, but also heat to bring it into bloom at this season, while this little beauty of which I speak is not only content but happy in the open.

If, as some hold, expectation is better than realisation, we who love the Daffodil ought to be supremely happy. All about us are the signs of a bountiful crop of the charming flowers of the *Narcissus*. Healthy leaves from which are emerging many buds give the prospect of a time when the silver and gold of the classic flower will be strewn far and wide, so that all may enjoy the wealth of beauty it yields. Daily, as we stroll round or work near them, we think of the promise of the future, and wait—not impatiently, for other flowers give us pleasure now—for the opening of these perfect flowers.

We have had for some time the earnest of the reward which awaits us in the curiously beautiful little *Narcissus minimus*. I call it "curiously beautiful" because it is. It is curious because of its miniature size, and it is beautiful with the most of the charms possessed by the more striking loveliness of its taller sisters. Its earliness is no slight

FIG. 68.—*LEUCOIMUM CARPATHICUM*.

merit. Ere passing from it, one would remark upon the variation among collected bulbs. Some few of the flowers may be like the small form first introduced as *minimus*, while others more nearly approach in size *minor* or *nanus*. Any one is worth having and worth protecting from the ravages of the slugs, which in some seasons delight in cropping the flowers, and thus depriving us of our pleasure in seeing these shapely little yellow flowers.

Never before have I had so much pleasure from *Hyacinthus azureus* (*Muscari azureum*). For one thing, it is now increasing quickly, and the greater size of the clump gives a brighter effect with its clusters of closely packed blue flowers. For another, the prolonged cold and snowfall have made it later, and one now reaps the benefit. It is shielded from its arch enemies, the slugs, by its zinc ring, whose sharp edges form a barrier to the foe.

But one must call a halt, even though our tale is not fully told. Much as one delights in telling of one's favourites, the tale may weary some. The garden, too, has its needs, and as one goes round more

and more work seems to await the hand of the lover of flowers. At this season there is much to be done that cannot be delegated to another. We cannot reap without sowing, and the hand of the slothful is of little use where plants abound. The work, however, is pleasant, too, and those who tend in the main their own flowers have sources of pleasure unrevealed to those who leave all to others.—S. ARNOTT.

Death of Mr. Thos. Boyd.

THE many friends of Mr. Thomas Boyd (fig. 69), late gardener to W. Forbes, Esq., Callendar Park, Stirlingshire, will be deeply moved to learn that one so well known and much respected was removed suddenly from our midst on Monday, 19th March. Our friend and neighbour had not been quite well of late, but indicated nothing to show that his end was near. His kind and affable manner had gained Mr. Boyd

FIG. 69.—MR. THOMAS BOYD.

many friends. Either as an exhibitor or judge at exhibitions he was most courteous, and possessed of an unassuming manner, which rendered him very popular. He was a native of Hopetown, near Edinburgh, and from early life had good opportunities of gaining a sound experience in gardening.

At an early period in his career he was well known as a successful exhibitor of fruits—with collections—and Grapes especially. He attended all the international exhibitions in England and Scotland, where his success was always well to the front, and returned

from the shows in possession of many of the most valuable prizes. He received for Grapes two Veitch Memorial prizes—in both cases they were Muscat Hamburgs. He also had many cups and plate which were won in hard contests at exhibitions. He gave a good account of himself for some years at Loch Ryan, Wigtonshire, while gardener to Sir W. Wallace. From there he went to Callendar, where he has so successfully laboured for over twenty years. Mr. Boyd was fifty-three years of age, has left a widow and large family to mourn his loss.—M. TEMPLE, *Carron*.

Hardy Lettuces.

CONSIDERING how badly some winter crops have withstood the weather, it is more than a little surprising to find the autumn-sown Lettuces have come through the winter so satisfactorily. Broccoli, Winter Greens, Spinach, and Sprouts fared badly, as also did an autumn sowing of Endive. The plants from the latter were intended for lifting to refill frames cleared of the early stocks, and were protected with a covering of leaves, but a severe, though short spell of frost completely destroyed them. Among the Lettuces there are surprisingly few casualties, especially with the Hardy Hammersmith and Bath Cos. Paris Market, which in some seasons stands well, and furnishes useful salading much in advance of the others named, succumbed to the frost, and Hicks' Hardy White Cos is less satisfactory than usual. In some springs I have found fuller ranks and better plants of the last named than of the Bath variety, proving that there is no uniformity of results.

Lettuces, like other winter crops, suffer when there is an excess of rain, even without much frost. This year the two first months were characterised by a superabundance of moisture, and some severe touches of winter frost. No less than 8½ inches of moisture were recorded for the two months—January 3.34, February 5.19. Some heavy snow storms contributed to this total, and while there was sufficient depth, gave protection to Lettuce crops. Under warm sheltered walls growth is now proceeding actively, and some plants are ready for

cutting. There have been seasons when as good material could be had in February; in others not until much later than the present moment. The value of these hardy Lettuces is much enhanced where frame room is not available for spring forcing, and even when this is so there is always satisfaction in having a good reserve to draw upon in times of pressure.

For the daily winter salad Endive has no rival, Lettuce taking its place from now onwards, or is used in conjunction with it. An early sowing of such a variety as Commodore Nutt, and the plants prepared for early planting by hardening in cold frames, comes in useful for spring supplies under the shelter of warm walls.—W. S.

Amaryllis Culture.

At a recent meeting of the Devon and Exeter Gardeners' Association Mr. Slade, the well known gardener at Poltimore Park, read an excellent paper on these handsome plants, prefacing his cultural remarks with some historical references. The chair was taken by Mr. Andrew Hope, and there was a good attendance. We make a few extracts from the paper as reported in a local contemporary.

At the outset Mr. Slade gave a brief sketch of the progress made by the hybridisation of these flowers during the past century. Dean Herbert hybridised the African and American species, and founded a new genus, which he named *Hippeastrum*, or Knights' Star Lily, whence spring the present race. He then spoke of the failure of the attempts by himself and others to cross the flowers of *Hippeastrum* and *Clivias*. The present race of *Amaryllis* sprang from various wild species. Many of these were named, and the history of the flower brought up to the seedlings raised by Van Houtte of Ghent, and De Graaff of Leyden, the latter of whom raised a hybrid named *Empress of India*, from which have sprung some of the best types. In 1867 Messrs. Veitch took the *Amaryllis* in hand, and having found Leopoldi and another species in Peru, commenced working with them, and by crossing with some of De Graaff's best forms, produced the very fine hybrids of the present day.

The essayist then passed on to the culture of the *Amaryllis*. A good compost is two-thirds of fibrous loam, one-third of cow manure, with a liberal portion of silver sand. These should be thoroughly mixed previous to potting. He himself generally used the refuse from an old Mushroom bed, and with excellent results. The *Amaryllis* should be under rather than overpotted, ample drainage given, and the soil be in a moist condition. January is the best time for potting. If not all potted at one time those left should be kept cool. In potting the bulbs every particle of soil must be shaken from the roots, and all decayed portions be cut away. The roots should be separated, and the soil carefully worked in among them. After potting a temperature of 50° to 60° is desirable, and if plunged in some suitable material it would prove beneficial at first—without bottom heat. A plant house or vinery of the temperature given were useful places for growing the plants in. He grew them in an intermediate plant house until after the flowering period, and then placed them in a vinery with more heat, but only partially under the shade. The plants were benefited while making growth by being plunged and a slight bottom heat given. After repotting no water should be given until the flower spikes and leaves have grown several inches. Then a moderate supply should be given till the flower buds show, when the quantity should be increased.

After flowering the plants should be placed in a warmer house, and slight shading afforded. As growth becomes more active water ought to be given liberally, with daily syringing to keep them clean. When the growth is finishing the shading should be gradually diminished, and water given more sparingly. Later on the shading may be removed, and water gradually withheld until the foliage is ripe, when they should be kept quite dry until they commence growing again. A Peach house, where the fruit has been gathered, and in which the bulbs can be exposed to the full sun, with abundance of air, is a suitable place to ripen them. Some growers do not pot annually, but Mr. Slade thought it better to do so unless the collection is a large one and the pressure of work heavy.

The bulbs may be increased by offsets, but new colours and varieties are raised from seed. In giving some advice how best to deal with insects, he said thrips were destroyed by fumigating, and red spider kept away by the syringe. The *Eucharis* "mite" may attack them if there are errors in watering in the early stages, but he was of opinion that neither *Eucharis* nor *Amaryllis* would be affected by the mite if properly watered. The two essential things to secure success in growing *Amaryllis* are watering and resting; given these, their culture is simple and easy, and they had a most useful flower, gorgeous in effect either in the cut state, or as a decorative plant for the mansion or conservatory.

A prolonged discussion took place as to whether the *Amaryllis* could be grown by gardeners having limited accommodation. Mr. Slade stated that it was practically as easily grown as the Hyacinth, and its treatment was of the simplest. Neither did the plant require any special assistance in the way of heating.

The Royal Horticultural Society.

Scientific Committee, March 13th.

Present: Dr. M. T. Masters (in the chair); Dr. Müller, Mr. Hudson, Mr. Im Thurn, Rev. W. Wilks, Mr. Lynch, and Rev. G. Henslow, hon. sec.

Grapes diseased.—Mr. Hudson brought some specimens which appeared to be attacked with the fungus *Glæosporium*. Dr. Masters undertook to examine it further.

Douglas Fir diseased.—Branches were received from Mr. Rogers of Penallowne, Cornwall. They were from young trees, planted in an old plantation. In some cases the whole tree was unhealthy; but in others the trees grow vigorously, and only the top dies. They were referred to Dr. W. G. Smith for examination.

Pear Stem constricted.—Mr. Rogers also sent a specimen remarkably constricted by a staple. The diameter of the stem being 2 inches, this was reduced to half an inch at the constriction. It had borne good crops of fruit up to last year.

Abies amabilis attacked by Chermes.—Dr. Masters showed specimens of this tree, also called *A. Lowiana*, with gouty branches. The bark was badly infested by an aphid much resembling that which attacks Beeches. The same remedy of syringing with petroleum emulsion is to be adopted if the trees be slightly infested; otherwise the only means of destroying the pest is to destroy the tree by burning.

Hydnora africana.—He also showed a specimen of this remarkable parasite. It is a fleshy, leafless plant, parasitic upon plants of the genera *Cotyledon* and *Euphorbia* in tropical and South Africa. There are about eight species. The specimen was received from Grahamstown.

United Horticultural Benefit and Provident Society.

THERE was a fairly large attendance of members at the Caledonian Hotel on the 12th inst., when this society held its annual meeting. It had been announced that Mr. S. T. Wright would occupy the chair, but unfortunately indisposition prevented his attendance. At very short notice Mr. Richard Dean undertook to preside, and beyond calling upon the secretary to read the minutes of the first annual meeting, he did not take up any time. The preliminaries having been disposed of, Mr. Collins was requested to read the committee's report for the past year, which was as follows:—

Report for 1899.

In presenting the annual report and balance sheet for the year ending January 8th, 1900, the committee have great pleasure in stating that the society continues to make progress in a very satisfactory manner.

Eighty-three members joined during the year, twenty-nine lapsed from various causes, two died, and two ceased to pay, being over seventy years of age; this leaves a net increase of fifty, the membership for the year being 791. The amount of subscriptions paid by members to the benefit fund, including arrears for 1898, was £1236 5s. 3d. The sick pay account was £206 2s., being £52 15s. less than last year. This is covered by deductions from members' deposit accounts of 6s. 5d. and 4s. 4d. respectively. There is a balance now in this fund (including £1201 15s. 11d. standing to the credit of lapsed members) of £12,190 9s. 2d.

The Benevolent Fund is now doing a useful work. Subscriptions amounting to £153 16s. 1d. have been received from honorary and benefit members, including £10 10s. generously given by W. Y. Baker, Esq., at the annual dinner. Various grants have been made from this fund, amounting to £66 5s. 6d. The Convalescent Fund continues to increase. Mr. Baker and Mr. Sherwood each gave a donation of £5 5s. at the annual dinner. Three members only applied for assistance during the year, the amount paid out being £4 only. The Management Fund shows a balance of £129 8s. 10d. The amount invested in Corporation Stock by the treasurer during the past year was £1500, the total invested funds being £15,850, and the treasurer has £153 14s. 11d. in hand.

The annual dinner passed off in a most successful manner, the chair being admirably filled by W. Y. Baker, Esq. The society's accounts were audited by Messrs. G. Dixon and W. Gunner, and found correct.

From the remarks of the committee as set forth above it can easily be gathered that the general affairs of the institution are in a most flourishing state, as indeed they should be considering the advantages derivable therefrom by members. The three funds known respectively as the Benefit, Benevolent, and Voluntary Convalescent, are all admirable, and happily each shows a material improvement in financial status over last year. The management of the society is in every way excellent, and it is evident that the sole desire of the committee is to do the utmost good with the money in hand. There are no lavish expenses for offices, while the secretary, as was remarked during the

evening, carries out his many duties for a surprisingly low salary. As we cannot give the whole of the balance-sheets we reproduce the one read by Mr. Jas. Hudson, the treasurer.

As we briefly noted on page 214 of our last issue, this shows a most satisfactory condition of affairs, and it goes without saying that any society that can cover the expenses of management by the aid of its interest on investments alone must have its affairs excellently conducted. The statement of its assets and liabilities is in the same eminently satisfactory condition.

In rising to move the adoption of the report and the balance sheets of the several funds, the chairman made several pertinent remarks, and while confining himself mainly to the statements set forth, threw out one or two hints that he considered worthy of the society's attention. These had in view the extension of the society's business amongst gardeners throughout the country, who either from apathy or indifference had not become subscribers. Mr. Dean congratulated the institution on the splendid progress that had been made, and deplored the fact that there were only 791 members on the books; hence the suggestions thrown out. He wished specially to bring the society before the younger generation of gardeners, and that much might be done in this direction cannot be doubted. In concluding, the chairman paid a graceful tribute to gardeners as a class, describing them as steady, thrifty, and industrious. Mr. W. Marshall seconded the motion, which was carried without a dissentient voice.

The retiring members of the committee were Messrs. Hemsley, Kelf, Winter, Summers, Cook, and Forman, of whom the four first named, being eligible, were re-elected, Messrs. Curtis and Stanbridge taking the place of the other two. Then followed several votes of thanks to various officers for past services, after which Mr. W. Marshall moved the following resolution:— "That the members of the United Horticultural Benefit and Provident Society, at their annual meeting held on March 12th, 1900, desire to record their appreciation of the inestimable services rendered to the fund by the late Mr. John Fraser, V.M.H., as their first treasurer on the formation of the society, and hereby tender their sincere condolences to his family for the irreparable loss they have sustained." This having been seconded, was carried unanimously.

In view of the amount of work that devolves upon the secretary it was proposed that his salary be raised to £52 per annum, but as this could not be done without notice of motion having been given, it was decided to give him a bonus of £10 over and above his salary, and refer the increase to the committee, who in turn would report to a special general meeting. This advance is thoroughly warranted, and we hope will be made. It was decided to print and distribute 5000 copies of the report. Other formal business having been disposed of, a cordial vote of thanks to the chairman closed the meeting.

Grassendale and Aigburth Spring Show.

THE first of the spring shows in our district was opened by the committee of the above society in the Grassendale Parish Room on Saturday last, and notwithstanding the difficult weather that has been experienced, the display of flowers and plants was bright and varied. As to the society itself, one rarely finds such a formidable list of special prizes, which goes to make up a sound financial concern and keeps it intact against weather and other causes. Then, too, Mr. Evans, the chairman, is thorough in every way, and his allusion to the assistance rendered by Mr. T. Johnson, the excellent secretary, and the committee, was well put and heartily received.

For twelve Hyacinths, Mr. F. Field, gardener to J. H. Wilson, Esq., Errington Lodge, Aigburth, staged admirably *Fabiola*, Queen of the

Blues, Grand Maître, and Lord Macaulay. Mr. F. Keightley, gardener to Mrs. Duncan, Prizett, was a good second. Mr. J. Heaton, gardener to R. P. Houston, Esq., M.P., staged a splendid six, whilst for six and three pots (three in a pot), Mr. G. Leadbeater, gardener to W. J. Davey, Esq., Holmleigh, Grassendale, scored. The six pots of Narcissus from the same grower were capital. Tulips were well timed and beautiful, the first prize singles and doubles falling to Mr. F. Keightley. Extra good were the pots of Lily of the Valley, Mr. J. Heaton winning a difficult position. The same exhibitor won with a charming plant of Begonia Gloire de Sceaux, also for three Callas.

The Orchid classes were fairly well filled, the fine specimen of *Odontoglossum Insleayi* (fifty flowers), and *Oncidium Cavendishianum* from Mr. C. Duke, gardener to F. Cross, Esq., 15, Fulwood Park, were stamped with the best cultural skill. For one Orchid Mr. J. Madeley, gardener to W. C. Atkinson, Esq., 5, St. Anne's Road, Aigburth, had a well flowered plant of *Ceologyne cristata*, and he also won the classes for one Rose, a trained *Maréchal Niel*, three grand *Spiræas*, and one *Rhododendron*. The forced hardy plants were capital, considering the weather, Mr. Leadbetter, with a handsome *Lilac* and *Azalea occidentalis* Queen Victoria, being well in advance from Mr. W. Bustard, gardener to J. McLelland, Esq., St. Anne's Road.

In the classes for Palms, Azaleas, and greenhouse plants Mr. F. Keightley was the prizewinner. *Amaryllis* from Mr. Leadbetter were of the choicest description, and this also applies to the grand *Cyclamens* staged by Mr. Heaton. The *Cinerarias* from Mr. J. Lewis, gardener to Mrs. Watts, Grassendale Park, and *Primulas* from Mr. T. Macklin, gardener to W. Harrison, Esq., The Coombs, were of the best quality.

The Young Gardeners' Domain.

Bits for the Bothy.

To Our Journeymen. (Continued from page 206.)

THERE is no more important part of a young gardener's progress than the intermediate stage of his journey through bothydom. Owing, perhaps, to some of the freshness, and a little of the novelty surrounding the life of a young recruit having been left behind, with the more responsible position of a foreman yet ahead, it may be regarded as a comparatively flat and uninteresting stretch of road; and, apart from this, a journeyman's life is apt to run a somewhat even course if he allows it to do so. Herein are advantages and disadvantages. For instance, a young fellow may be told off to a post in the fruit department or the plant houses, and once having grasped the routine of work meted out to him have to hold that post for some considerable time. The exigencies of a large gardening establishment often demand this, and many a head gardener on finding a subordinate working smoothly and satisfactorily, forming, as it were, an important piece of mechanism in his complex machinery, feels reluctant to disturb it by making changes. Thus, one phase of work may not only monopolise a young student's time in one situation, but, as has occurred in some instances, be prolonged by his adaptability and fitness for it in another.

"Have you a young fellow you could send me for my Orchid houses? I want one who has a good grasp of the subject." Thus wrote one head gardener to another, and a young man who had been solely among Orchids for three years, for higher wages and the work that he loved, readily exchanged into what was practically no change for him. As with this, so in other departmental lines have similar cases been observed. That the system is not a common one is admitted, but sufficiently in evidence it is thought to claim the attention of our lads here, as well as to account for some things in after life which cannot otherwise be easily explained. That it possesses advantages is obvious, for not only are the details of the one particular phase of work, like an oft repeated lesson, thoroughly mastered, but at this receptive age of life our journeyman is metamorphosed into a specialist; and, in all probability, his whole life and life's work will bear the impress of individuality. If men thus trained could find positions for life as specialists, for which they are so eminently adapted, well and good, but the demand for such is extremely limited, and it is generally well understood that our boys of the bothy are to all intents and purposes intended for gardeners in its broadest and most comprehensive sense. Taking this to be their objective, they should not under any circumstances ever lose sight of it, lest on obtaining their commission they should be found wanting.

At first sight this matter is to some extent one over which a young man has little control; how much the more necessary is it, then, that he should avail himself of every opportunity, however obscure, to obtain a practical knowledge of what he must sooner or later profess to know all about. Employers, however, are generally willing to stretch a point when it becomes plainly apparent to them that their young men are really anxious to learn, and willing to make small personal sacrifices in order to do so. Perhaps the simplest way of carrying an object lesson home will now be to personally address some young reader who finds himself among this restricted class it has been the endeavour to depict. As previously stated such cases may be exceptional, but in reality there is scarcely a garden, or a young

gardener, to which the principle does not apply in some degree. To clear the way a clean jump may be made from the journeyman's position as a budding gardener to that stage where he blooms out in all the glory of a "head."

What excuse have you, young friend, when, having accepted the responsibility of the care and management of a good garden, some prominent part of it eventually becomes a speaking witness of ignorance or neglect? We will say the wall trees, for instance, over which there has been of late some pertinent discussion in these pages. Will your skill as an orchidist or a plantsman atone for this or any other important deficiency? No. There is no excuse. You may shine in the show among fine specimen plants, but a cloud will hang over those garden walls fatal to your character as a gardener—a gardener, be it understood, not a specialist. Can you imagine any of our leading gardeners having blindly rushed in to accept the onerous position without having made themselves conversant with so prominent a part of it? Scarcely, one thinks.

Feeling, it is hoped, the absolute necessity of bringing as far as possible the whole curriculum of elementary training into bothy life, the question arises, How is this to be done? It is a simple question, but resolves itself into a compound one—viz., can a young man go far enough on his own initiative to cover all the necessary groundwork of his primary tuition, always supposing that some practice, however limited, is essential to a proper grasp of most subjects? Or, secondly, will his chief meet him half way in the matter, and with a friendly hand help our young journeyman to lift himself out of the even tenor of his course in order to fit himself for the front? To the whole question—Yes. But in many cases, and there is no reason why it should not apply to all, the advantages will have to be mutual—viz., to the benefit of both master and man.

Harking back momentarily to the life of a young recruit, it will be remembered that in a previous paper the necessity of making recreation subservient to work was placed well to the front. Supposing this to have been happily carried out, the earlier difficulties surrounding the efforts of a recruit will have long since disappeared, and what was really hard work will, to a journeyman, have resolved itself into a positive pleasure. Not only that, but it will now fit admirably into this more advanced stage. Our journeyman, as well as being body and soul in his appointed daily task, will take the keenest interest in all that is going on around him. To do this nothing is more helpful than daily notes in his diary—viz., notes of the whole routine of work from which his hand is excluded save his own particular phase of it. This can be done unobtrusively; a walk round of an evening, with a companion, if convenient, to chat over matters going on, is a pleasant and profitable method of grasping details. If this keen interest is taken, there is not, it is believed, a head gardener in existence who will not unbend from that reserve he may think it necessary to employ during the legitimate working hours and give his young men the opportunity to approach him for help and advice.

In the matter of wall trees, for instance, is there any "head" who would refuse to allow his young hands to take sole charge of, say six trees each, and this in their own time as a recreation? With, say, three in the bothy, that would be eighteen trees, or it might be that one length of wall could be divided among the young hands in sections. Such, or a similar system, which might be readily applied to other phases of culture, a length of herbaceous border possibly, could not fail to be of the greatest educational value to embryo gardeners, as well as of material assistance to him who is responsible for all—men as well as master; and, I take it, few head gardeners care or wish to divest themselves of the responsibility they undoubtedly have regarding their pupils. Here, too, competition amongst the young men themselves comes in, with its stimulative aid, besides a score of moral advantages contingent upon it. "Oh! this is all very well," some head gardener may say; "you don't know my lads." "Granted;" yet reasoning from what is known of the class to which they belong, with its grand reserve fund of high spirits and superfluous energy, that anyone should think it cannot be utilised for their advancement, for the good of all concerned, and for the glory of gardening, is probably as great a mistake, as it would be a matter for regret to—

THE OLD BRIGADIER.

(To be continued.)

Lachenalia tricolor.

CONSIDERING the little trouble entailed in growing this pretty and useful bulbous plant successfully, it is surprising they are not given a place in every collection. For an edging on the conservatory or greenhouse stage in early spring they are almost unique; and the peculiar combination of colours in the flowers makes them very conspicuous. About the middle of August is a good time for potting the bulbs, the largest and best ripened always being selected. The compost should consist of good loam three parts, leaf mould one part, pulverised cow manure one part, and a fair sprinkling of sand or mortar rubble.

The most serviceable pots are 5-inch, and they will need only a small quantity of drainage, covering it with a little of the rough fibre from the loam, to prevent the finer particles working down among the crocks. Five bulbs placed in each pot will be sufficient, and the soil must be

made firm. After potting stand the pots out of doors, and cover them with cocoa-nut fibre refuse or ashes till growth commences; they should then be transferred to a cold frame, where they will obtain abundance of air and light, as these are indispensable factors in producing the best results. If it is desired to have them in flower earlier, they may be placed in an intermediate house or heated frame, and should be raised as near the glass as possible, or the foliage will become drawn.

When the pots are well filled with roots, they will benefit by occasional applications of liquid manure or soot water; and it may be continued with advantage till the bulbs are almost ripe. After flowering, the pots should be placed in a cold frame in the full sun, till the leaves have completed their work and the bulbs are thoroughly ripe, when they can be stored away in a dry position till the time again arrives for potting.—*ASPIRANT*.

Forced Bulbs.

THERE are numberless bulbs annually consigned to the refuse heap, or otherwise wasted, which if taken care of and planted in bare places by the side of woodland walks and pleasure ground borders, would go far to render them at certain seasons the most attractive portion of the demesne. In no situation are plants of this character so attractive as when they are associated with woodland scenery, springing through a carpet of green grass, which shows them off to advantage. Planting in rows, as is generally done in beds, favours a formal appearance, but dotted about under deciduous trees or shrubby borders, encourages a much more natural aspect.

Although the bulbs may not produce such large flowers, or spikes as when planted in rich soil in the open, the deficiency is made up by the splendid masses they attain to when left undisturbed, as they can be in such plantations. In order to give them a fair start the soil should be broken up to a good depth, and some short well decomposed manure worked in at the bottom, which will add largely to their strength and vigour. A soil that is light and open is most suitable, and in this practically all bulbs will flourish and increase rapidly. There are places in all gardens that may be much improved and beautified by such planting, for if there is only a single shrub or specimen tree of any kind its beauty will be greatly enhanced by a few clumps of bulbs around it. Beds of Rhododendrons, Roses, and shrubberies are considerably enlivened, and the bulbs do very little harm.

Every care should be taken of the plants after flowering is over, owing to the tender state they are in from being subjected to heat, and the sudden transition therefrom. It is no uncommon thing to notice numberless bulbs of different descriptions thrust out into the open and exposed to cutting winds directly the flowers fade. The proper way to treat them is to stand the pots in a light airy position in a cool house or pit, and administer just sufficient water to keep the soil moist till they show symptoms of going to rest naturally, after which they may be placed in the positions assigned them.—*BRASSICA*.

Fruit Forcing.

Vines.—Earliest Houses.—In the very early started houses colouring will shortly be proceeding. Afford a thorough supply of tepid liquid manure and mulch the border at once with an inch or two thickness of partially decayed manure, preferably rather lumpy. The mulching must be sweet, then it gives a stimulus to the roots and secures healthy foliage. Damping should be continued until the Grapes are well advanced in colouring, after which reduce the moisture gradually, and insure a circulation of warm air day and night by regulating the ventilation judiciously. In most cases the thorough moistening of border at the time of changing colour will suffice till the Grapes are ripe, but there must be no lack of moisture, or it may cause the premature ripening of the wood and the loss of the principal leaves. The temperature should be maintained at 70° to 75° in the daytime, with a rise of 10° to 15° from sun heat, allowing the temperature to fall during the night to 65°, or even 60°.

Vines in Flower.—A circulation of warm, rather dry air, and a temperature of 65° to 70° at night for Black Hamburgh and similar varieties, and 70° to 75° for Muscats, facilitates a good set. Muscats and other shy-setting varieties should be brushed over with a camel's-hair brush about the time the blossom is fully expanded, so as to rid the stigmas of the caps and glutinous substance, choosing a warm part of the day after the house has been rather freely ventilated. The operation will render the flowers fitted for fertilisation, effecting this by brushing them over with a brush surcharged with pollen taken from free-setting varieties, such as Alicante and Black Hamburgh.

Disbudding.—The Vines in midseason houses will require attention, not attempting it, however, until the bunches appear in the points of the shoots, and then it ought not to be done in a hurry, nor a large reduction made at one time. Proceed gradually and with discrimination, so as to give as little check as possible to the Vines. Retain no more shoots than can have full exposure to light, crowding being a great evil. Allow for the due extension of the laterals, for on this depends sustained root activity till the crop is perfected.

Stopping.—Permit the bearing shoots to extend according to space. If this is restricted by the Vines being close, the shoot may be pinched at the first leaf beyond the bunch, and this should be done when the leaf is the size of a penny. When there is a moderate space between the rods allow two joints beyond the show for fruit. Where there is abundance of room let the shoots with fruit extend three or four leaves beyond the bunches before taking out their points. Laterals below the bunches may be rubbed off, except from the two lowest leaves, pinching them at the first joint. But laterals above the bunch may either be pinched to one joint or allowed to extend until the available space is covered or nearly so, then pinch, and keep them within bounds afterwards by stopping to one joint of growth as made.

Thinning.—Remove all superfluous and duplicate bunches before they flower. Setting depends on the good form of the bunch, and on its receiving the essentials of fertilisation. Free setting varieties may have the berries thinned as soon as they are out of flower, but Muscats and other shy setters should not be thinned until it is seen which berries have been properly fertilised by their taking the lead in swelling. Every berry should have room to swell without becoming wedged, and yet leave enough berries to insure the bunch retaining its form when cut.

Watering, Feeding, and Mulching.—Vines require very moderate supplies of water until they are in leaf, sufficing that the soil be kept moist, but when the leaves are full sized the evaporation from them is considerable, and from that time until the fruit ripens they must not lack water at the roots. The watering should be regulated according to the requirements—dimensions and formation of the border. A narrow border will require watering twice as often as one double the width, assuming the Vines to be equally extended and cropped, while a border of loose material will need water much more frequently than one formed of firm retentive loam. Due regard, therefore, must be had to the state of the Vines in relation to the rooting area and to the weather, as water will be required much oftener in hot dry weather than when cold and dull. The proper procedure is to examine the border, and when water is required give it abundantly. Surface dressings of artificial manures, such as those advertised, are of great benefit for the health of the Vines, and the swelling and perfecting of their crops. A dressing of about 4 ozs. per square yard may be given as soon as the Vines start into growth, another after the Grapes have been thinned, a third during stoning, and a final one when the Grapes commence the last swelling, or just before or when beginning to colour. Liquid manure acts more promptly, and may be supplied whenever water is required, taking care that it is not too strong, and is warmed to the mean temperature of the house.

Vines restricted to narrow borders will need higher feeding than those with large rooting areas, affording liquid manure whenever water is requisite, but it is well to change the food occasionally. A mulching of short manure, sweet and lumpy, such as stable litter freed of straw, about an inch thick, and added to from time to time so as to maintain that thickness, is excellent for ordinary borders, but those composed of light porous materials should have a mulching of well decayed manure, as it lies closer, and the roots of the Vines are attracted to it through its retaining moisture better and longer.

Late Vines.—If started in February or early in this month they will be swelling their buds and have all the growing season before them. Use the syringe twice a day, seeking to secure a good start by closing the house with a genial humid atmosphere, but not a saturated one, at a temperature of about 75°. The canes of young Vines having been brought to a horizontal position the buds will break evenly; if not depress the points still more. Bring inside borders into a thoroughly moist but not sodden condition. The outside border will be sufficiently protected by a fine tilth of soil, or if firm and close at the surface a light mulch of lumpy, partially decayed material will protect the young fibres from chill, and accelerate surface rooting while feeding the Vines. When lumpy and not more than a couple of inches thick it is of great benefit in preserving uniform moisture, while admitting of the free access of the sun's warmth and of rain and air.

THE BEE-KEEPER.

Useful Spring Flowers.

IN recent notes a few shrubs and trees were mentioned as being ornamental, and when in flower beneficial to the bees owing to the pollen or honey they produced. It may be of interest to remind bee-keepers how necessary it is to be constantly planting a selection of the many useful spring flowers, which always prove interesting to the lover of a garden, while many of them in their season produce an abundance of honey or pollen.

It is now too late to plant bulbs, as the majority of these were planted last autumn, and with favourable weather will soon be in bloom. There is one exception, however; all bulbs that have been forced should be taken care of, and when properly hardened may be planted. We force bulbs extensively, and as a fresh stock is obtained annually for this purpose we make a rule never to destroy any. Our usual plan is to plant on the outskirts of the shrubberies, or under the trees in the grass. The machine is kept off these places until the tops have died down. Treated in this manner they yield an abundance of bloom, and some varieties increase at a rapid rate. Many thousands which would otherwise be wasted are planted each spring, with the result that what was previously rough grass or waste land is in its season bright with flowers.

Spring flowering plants are better if planted in the autumn, but owing to the wet weather that prevailed during the latter part of last year the work was in many cases delayed. It may be done at this season with every chance of success. Aubrietias, Arabis, and Wall-flowers should be planted in quantity; an open space ought to be selected, where they can obtain full benefit from the sun. Primroses in variety and Myosotis may be utilised in smaller numbers. A large breadth of Limnathes Douglasi should be planted; this is a dwarf growing plant much visited by bees. In the kitchen garden plant out in their permanent places the small plants that were raised last year of Thyme, Sage, and Borage; these are all excellent honey producers.

Condition of Stocks.

The temperature continues low, but with the advent of finer weather and sunny days an examination of all the colonies should be made. Bees, we fear, have not wintered well, as already there are reports to hand of serious losses. This is probably owing to late feeding, and the wet season followed by severe frost. It is therefore advisable to examine each stock, and make a note of its condition. This is easily done if each colony is numbered and entered in a small book, which may be carried in the pocket. This is the plan we have adopted for many years, and it is interesting as showing the condition of each colony in the apiary; it also shows the history and age of each queen, and is useful for future reference, and if properly carried out saves a great amount of labour in examining stocks.

If a colony of bees is in good condition at this date and well supplied with stores it will not be necessary to examine it again for at least two months. A stock, however, that is short of stores and weak in bees will require constant attention. Thus by looking at the number on the hive and comparing it with the book one knows at once which requires attention. If only a few hives are concerned it is not so important as when there are upwards of three dozen in the apiary.

If, on examination, stocks require feeding, it will be advisable to place a cake of candy over the cluster and cover up as warm as possible. It is still too early to use syrup. As the queen will soon be active patches of brood will be visible, and care must be taken in removing the combs that it does not become chilled. The less bees are handled at any time—but particularly during early spring—the better. Remove all damp coverings and replace them with those that are dry, clean the floor boards, and make all as dry and warm as possible. If there are any dead bees remove them, or they will encourage robbing.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Sub-tropical Gardening (E. T. H.).—We know of no book exclusively devoted to this phase of gardening, but many excellent articles have appeared in the pages of the *Journal of Horticulture* on the subject. We will endeavour to arrange for one or two practical articles that will be of service to you.

Cypripedium insigne (R. W. M.).—This popular Orchid will thrive in the same pot for many successive years, even after the roots have become a mass, if plenty of water is given to it at the roots and over the foliage during the season of growth. The roots cling firmly to the pot, and in potting it is always wise to break the pot and leave the portions attached when placing the plant into a larger size. In potting this plant, which may be done early next month if it really needs it, you must fill the pot in which you are going to place it about half full of drainage, and the plant should be well elevated above the rim of the pot. The best compost is fibrous peat and living sphagnum moss in equal proportions, with lumps of charcoal or portions of broken pots freely intermixed. The whole of the decomposed material should be carefully picked out from amongst the roots without breaking them, and the new as carefully worked amongst them again.

Liliums in Pots (Tyro).—Do not remove the old roots from the Lilium bulbs if they feel plump and firm to the touch, but if dead or dying then remove them with a sharp knife. The plump, firm roots will, when planted, throw out lateral roots, and thus support the bulbs until new roots are formed direct from the bulbs. If the bulbs are flabby and somewhat withered, put them in a box and cover with cocoa-nut fibre refuse for a week or ten days before potting. Ordinary garden soil is not usually to be found good enough for growing Lilies in pots, and yours, we suspect, is no exception. Sound fibrous loam two parts, well-decayed manure one part, and good coarse silver sand another part, is necessary to grow those varieties you name to the best advantage. After potting place the pots in the cold frame, plunging the pots over the rims in coal ashes or cocoa-nut fibre refuse, and giving no water until the bulbs begin to grow. By that time the pots can be stood in the open air, and remain there until they flower or until the end of August, when remove them into the greenhouse.

Onions for Pickling (H. T. H.).—The Onion usually grown for this purpose is the well known Silver Skinned, though many persons now utilise the Queen, both being cultivated in precisely the same manner. The best system to adopt is undoubtedly that of the market gardeners, who turn over a piece of ground, bringing up a layer of the poor subsoil, and spread this 5 or 6 inches thick on the surface. This poor soil is made fine enough on the surface for sowing, and on it seeds are scattered broadcast, very thickly indeed late in the spring—the end of April or early in May. So lavishly is the seed used that the plants appear "as thick as grass." There seems to be just enough food in the soil to sustain them for a time, or in other words, sufficient for the growth of small bulbs only. The plants commence withering early, and we have seen the mass of "picklers" almost so closely packed together that the soil could scarcely be seen between them. After the bulbs are cleared off the ground is turned over again, bringing the better soil to the surface once more, and the land is in splendid condition for autumn crops.

Abutilons after Flowering (F. S. S.).—After flowering the plants may be cut down, and the young shoots will root freely if made into cuttings, and inserted in sandy soil and placed in gentle heat. The old plants should be repotted when they have made fresh growths about an inch long, reducing the ball about a third, returning to the same size of pot, keeping rather close, shaded, and syringing twice a day until they have recovered from the potting. Early in June they may be given the flowering pots, and stood outdoors in a sunny situation, where they may remain until late September, and then be taken under glass.

Spent Malt for Orchids (Constant Reader).—Some of the finest *Odontoglossums* in this country are grown on lattice stages over a lower stage of broken coke, and you will be well advised to grow your plants in the same way. Certainly you will gain nothing by plunging them in spent hops or malt. In all Orchid cultures abundance of fresh air to the roots is an important detail, and in none more than that of *Odontoglossums*. This you would prevent by plunging them in any material, and you will be wise if you leave it alone. Make your lattice stage so that it stands about 6 inches clear of the lower one, and cover the latter with broken coke or shingle kept constantly damp. If this is done, and other cultural details properly carried out, you need have no fears as to the result.

Impressions of Ferns (Journeyman).—You will find the practice of taking impressions of Ferns most interesting; we have seen some pretty pictures formed by tastefully grouping a number of different fronds on a sheet of paper. The fronds of which an impression is desired should be carefully pressed first, so that all the parts are flat and firm; then they can be placed on the paper, which may be secured to a drawing board, and pinned in position. This requires to be done with care, and if the fronds are moved during the process of stippling, imperfect representations will result. When the fronds are fixed the brush can be slightly moistened in ink, and the paper either lightly dotted with the brush, or the ink can be jerked on by a quick movement of the hand. Very little ink must be taken in the brush at one time, or a heavy and smudged out line will be obtained. Practice will soon enable you to manage this, and when several fronds are grouped to form a picture the effect can be greatly improved by a kind of shading, deepening the application of ink in some places and lightening it in others. The space covered is left white when the fronds are removed, showing their outline with exactitude when the work is well done.

Polyantha Roses in Pots (G. P. J.).—Both the climbing and dwarf varieties of *Rosa polyantha* grow and flower very satisfactorily in pots, indeed they are too tender to plant outside otherwise than in a sheltered situation. If your plants belong to the climbing section, you must either train the shoots up the roof of the greenhouse, or fix a long stake in the centre of the pot, and train the shoots to it to form a pyramid. Very little pruning is needed with this class of Rose, except removing all thin weakly looking shoots, and just the tips of the stronger shoots. If pruned too much they will fail to flower. The dwarf varieties too require simply the removal of weak shoots, and shortening of the stronger ones where necessary to form the plant into a good shape. After a year or two the growths will become crowded, and these must be thinned out by removing a few of the oldest shoots. After the plants have begun to develop their flower buds, top-dress the roots with a little well-decayed manure, and water once a week with the following stimulant:—1 oz. of guano, dissolved in a gallon of rain water. The plants will do well in the greenhouse, but care must be taken to avoid their being subjected to cold draughts. The treatment applicable to pot Roses generally will be suitable for the after-management of the *Polyantha* Roses. If you refer to the instructions which appear from time to time in these pages on Rose culture, you will find full details of any further information you are likely to require on the subject.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. W.).—The *Calceolaria* is possibly *amplexicaulis*, but it is impossible to say definitely. Send flowering specimens when you have them, and we shall be glad to assist you. (M. C.).—As we have stated before, *Crotons* can only be positively identified by comparison in a large collection. (S. N. B.).—1, A good form of *Dendrobium nobile*; 2, *Cymbidium Lowianum*; 3, *C. eburneum*. (T. C. R.).—1, *Bignonia triphylla*; 2, *Veltheimia viridifolia*. (W. F.).—1, *Dendrobium luteolum*. (W. C.).—1, *Phlebodium aureum*; 2, *Thibaudia acuminata*; 3, *Saxifraga granulata*; 4, *Primula denticulata*; 5, *Selaginella stolonifera*; 6, *Habrothamnus elegans*. (W. A. B.).—1, *Eriostemon scabrum*; 2, *Libonia floribunda*; 3, *Boronia pinnata*; 4, *Hederoma fuchsoides*; 5, *Hepatica angulosa*; 6, *Begonia metallica*.

Foot and Mouth Disease.

AN outbreak of this disease on the borders of Suffolk and Norfolk on January 29th, followed, as it has been, by six other outbreaks in the same district, is matter for great concern on the part of breeders of stock. Farmers who have experienced an outbreak of this complaint amongst their ewes at lambing time, or amongst their dairy cattle, will be able to give graphic details of the great loss and

annoyance caused by it, and will be able to impress upon the younger generation a wholesome dread of a return of such a visitation.

That it is a very contagious disease there is no doubt, but we do not think it is conveyed by the air. Thirty years ago we were upon a farm that for three years was rarely without a case of foot and mouth. No breeding herd was kept, but store cattle were bought as required in Yorkshire markets. During the time that the disease was so prevalent every animal purchased was treated as being a probable patient, and very few escaped. The autumn months were those during which the principal purchases were made; the animals were placed in one of two yards separated from the main farm premises, and used as hospitals or, rather, sanatoriums, for many of the cattle were suffering from the disease when bought, and already past the worst stages.

As they became convalescent they were disinfected and drafted off amongst other cattle. Half a dozen milch cows were kept on the main premises, but these never took the complaint. A flock of ewes was lambed every year in one of the hospital yards, after the latter had been cleared of cattle and manure for some time, and no outbreak of foot and mouth took place amongst the ewes, so it is fair to suppose that the contagion is not so very easily conveyed, and may be avoided with reasonable care. For either two or three seasons lambing was proceeding, and foot and mouth disease existent within a radius of 100 yards, yet no evil effects befell the ewes. The only safeguards used were disinfection of appliances, both permanent and movable, and prevention of all communication between cowman and shepherd; to aid the efficiency of the latter precaution a separate cake supply was provided for each.

Farmers in other parishes were not so fortunate, and where the disease attacked a breeding flock very serious loss was incurred. On some farms the greatest loss was from abortion, induced during the later periods of pregnancy, whilst many old shepherds have vivid recollections of the almost heartrending experience they had to struggle through when lambing began. The loss in the case of the dairy cow arose from the diminution of the milk supply, which would almost cease, never to be even nearly regained in convalescence.

Fatal results were not to be feared in cases of cattle over a year old, but calves were difficult to bring back to a state of health if seriously attacked. For the information of those who have not been familiar with this disease, the symptoms are lameness, caused by inflammation in the hoof, and frothing and running saliva, caused by a similar state of thing in the mouth; the latter symptom is generally noticed before the lameness.

The disease is simply a fever, and is caused by a bacillus, but whether it can be induced by a state of low nutrition, accompanied by overdriving and insanitary conditions, has not been proved, though many people believe it can be. At any rate, when the epidemic was at its height it found genial soil for development in the droves of store cattle brought long distances and badly fed, whilst being mercilessly driven from market to market. Our experience in treating the disease teaches the adoption of a negative policy, except in the case of very young animals. Older cattle will go through the stages of the complaint best if they are let alone. Cleanliness and ventilation must be attended to, but little else need be done. For a few days, when the complaint is at its height, the animal will have little desire to eat, and should not be forced. It should have a small supply of finely crushed linseed cake within reach, and also a little very soft hay. This is the first thing the beast will fancy when it has got a turn for the better, and the disappearance of the hay may be taken as a symptom that the worst is over. As soon as he is better he will amply make up for lost time as regards eating. In cases of great debility oatmeal gruel may be given, but only in cases of real necessity, for the use of the horn must have a very irritating effect on the mouth. Recipes to aid the curative processes of Nature are:—

"Honey, 1 lb.; muriatic acid, 1½ oz.; mix them well. Apply a small dessertspoonful to the tongue three times a day, leaving the animal to distribute it over the mouth by the champing motion which is sure to follow its application."

"For the feet, take aloes ½ oz., rectified spirit ½ pint, alum ½ oz.; dissolve them in 1 pint of water; mix, and apply a little twice a day between the claws.

Hyposulphite of soda is a good thing, 4 ozs. being given dissolved in water to each animal twice a week.

We are glad to notice from the latest reports that there have been no further cases, and hope that the outbreak may soon be stamped out. Surely it cannot be necessary to go to the extremity of ordering compulsory slaughter. Our view is that sufficiently stringent isolation and disinfection should be efficacious in preventing the spread of the disease. Local authorities ought to have full discretion as to deciding upon slaughter or otherwise; but the burden of enforcing the regulations as to isolation should also rest on their shoulders; the rules should be very stringent, and local inspectors be made responsible for any laxity.

Show Prize Money.

Looking carefully through the prize lists at the recent horse shows we are struck with the fact that such a large proportion of the prizes, especially of the leading prizes, goes into the pockets of men of great wealth. Naturally this is only to be expected, for many of the animals are purchased for large sums from the breeders expressly with a view to winning these prizes. That such ambition on the part of wealthy men does much to encourage breeding is obvious, but we must confess to a feeling of satisfaction when we see the name of a tenant farmer occupying the place of honour in connection with an animal of his own breeding.

Work on the Home Farm.

We are enjoying beautifully dry sunny weather, and prospects of spring work are much brighter. Here and there we see a drill at work, but have seen nothing very satisfactory in that line yet. Wheats are looking well though backward; there has been little loss of root, and the large rain and snow falls have solidified the land and almost done away with any necessity for rolling. Now the surface is dry, however, the two-horse Cambridge roll taken over the ground once will do good and prepare it for a good harrowing. With a full plant and some to spare it is always good policy to harrow Wheat; on light soils, where weeds are numerous, harrowing is almost a necessity, and should be done in February. This was quite an impossibility this year, but now the land is dry it should be done at once.

The Mangold crop has proved so valuable this year that we doubt not that a larger area will be sown this spring. In six weeks time the seed should be sown, and as a good mould is most essential to the germination and successful growth of Mangold steps must be taken at once to prepare the ground; for this crop succeeds best on heavy or even strong soils, and such are not now in a very promising state. The land must be worked at once with the cultivator, rolled, and, if there is any twitch, it must be harrowed out, then rolled and harrowed again. If the land be clean, as it should be for Mangold, drag and roll, then harrow and roll, wait a few days, and repeat the process, always leaving the surface as smooth as possible to avoid loss of moisture. It is quick drying that makes clotty surfaces. If the land has thus been deeply stirred in March and the surface kept close it should plough over in a nice mellow condition by mid-April. This is a grand time for planting Potatoes, and farmers who cannot get on with Barley sowing are glad to get their Potatoes put in.

We again urge our friends to sow their Clover seeds after the corn drill; there is no other sure way of getting a good plant of seeds. When the seeds have been mixed do not put them into large sacks but into small parcels, for if put up in big lots the heavy seeds are apt to gravitate to the bottom before they reach the field; thus if care is not exercised Clovers may be sown alone in one part of the field and Ryegrass in another.

Lambing still proceeds satisfactorily, the only drawback being scarcity of spring keep. Happy is the man who has a good plot of Kale.

IRISH OR AMERICAN BACON.—The inspector of the Bacon Curers' Association has been making his presence felt in Dublin lately. On Wednesday last a very important case was heard in which the large firm of Messrs. Williams & Co., Ltd., were summoned at the suit of the Association for having sold an American ham as Irish. The police magistrate (Mr. Mahony) took a very severe view of the case, and imposed the maximum fine of £25, with £5 costs, and stated that if any more cases of the kind came before him he would use his powers and give a sentence of imprisonment without the option of a fine.—("Rural World.")

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH

NOVELTIES & SPECIALITIES FOR 1900.

Amaryllis, Barr's Choice New Hybrids, saved from a magnificent collection. Per packet, 2/6.
Aster sinensis, a lovely single Aster, with large handsome flowers of a delicate mauve with yellow disc, bushy, branching habit, ht. 15 in. Per packet, 1/- and 1/6.
Candytuft, Barr's Giant White, very large spikes of snowy-white flowers. Per packet, 6d. and 1/-.
Celosia plumosa, Barr's Choice Mixture, handsome feathery plumes of bright colours. Per pkt., 6d. & 1/-.
Lantana, Barr's New Dwarf, a mixture of brilliant colours, charming as a pot plant. Per packet, 1/6.
Lupinus arboreus Snow Queen, a pure white Tree Lupin, fine novelty. Per packet, 1/- and 1/6.
Mignonette, Barr's Covent Garden Favourite the finest Mignonette for pots or borders, the handsome flower heads are deliciously fragrant. Per pkt., 6d. and 1/-.
Nicotiana glauca, a fine white-flowered Tobacco with handsome foliage. Per packet, 6d. and 1/-.
Petunia, Barr's Superb Giant, the largest and handsomest of all the Petunias, immense flowers of rich and varied colours. Per packet, 2/6 and 3/6.
Phacelia campanularia, one of the most lovely blue flowers in cultivation, height 8 in. Per pkt., 6d. and 1/-.
Poppy, Empress of China, snow-white single flowers, with a fringed margin of crimson-scarlet. Per pkt., 6d.
Poppy, Shirley, Barr's extra selected strain of this beautiful annual Poppy. Per packet, 1/-.
Rose, Miniature Fairy, dainty little semi-double flowers of various shades, blooms first season. Per pkt., 6d. & 1/-.
BARR'S SEED GUIDE contains a Select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

BARR & SONS, 12 & 13, KING STREET, COVENT GARDEN, LONDON.

WARE'S SEEDS

NEW AND RELIABLE

Finest FLOWER SEEDS.

Hardy and Half-hardy Annuals.
 Biennials and Perennials.
 Florists' Flowers.
 Greenhouse and Conservatory.
 Everlastings and Ornamental Grasses.

Choice VEGETABLE SEEDS.

COLLECTIONS FOR SMALL OR LARGE GARDENS,
 To give an ample supply of well selected Vegetables during the year, 10/6, 15/6, 21/6, 42/6, and 63/6.
 Full particulars of any of the above Collections on application.

DESCRIPTIVE CATALOGUE, BEAUTIFULLY ILLUSTRATED, has been posted to all Customers, and may be had free upon application.

In addition to SEEDS, the Catalogue contains also particulars of:—

NEW BEGONIAS FOR 1900

CHRYSANTHEMUMS,

LILIES, GLADIOLI, DAHLIAS, &c., &c.

N.B.—We pay Carriage, and send packing free on all orders for Bulbs and Plants of 20/- and upwards when accompanied by cash. All Seed Carriage Free.

 Hale Farm Nurseries,
TOTTENHAM, LONDON.

No. 1031.—VOL. XL., THIRD SERIES.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM
 AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is **ECKFORD'S GIANT SWEET PEAS**. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40! Collections from 1/6 upwards.
 (See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CRISPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that **ECKFORD'S SEED**, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/6, 42/6, 63/6, 105/6, all carriage paid. Other Collections, 2/9, 5/6, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelty and Grand Collection of named varieties
PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLAKED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! **ILLUSTRATED Catalogue & Cultural Notes POST FREE!** If you love Gardening send for one!

HENRY ECKFORD,
 SEED GROWER, WEM, SHROPSHIRE.

BEGONIAS, TUBERS & SEED.

THE BEST COLLECTION. Catalogues Free.

Seed, Double and Single, choice, each 1/6 and 2/6 per pkt. Extra Superb Hybrid, from newest and best flowers only, each 5/6.

B. R. DAVIS & SONS, NURSERIES, YEOVIL, SOM.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirit to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE" is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

"WEST'S INSECTICIDE" can be proved to be the best and cheapest by sending for a free sample box.

For particulars of West's Patent "Ivorine" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Crocks, West's Fertiliser, West's Weed Killer, West's Lawn Sand, &c., &c., see ILLUSTRATED CATALOGUE of WEST'S PATENT GARDEN SPECIALITIES, post free.

Samples free; postage for samples and goods extra. All goods made on the premises by C. E. West.

Gratis, "Orchid Culture," 3rd Edition, postage 2d., Gives full particulars of the cultivation of Orchids.

The Journal of Horticulture can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

The New Chiswick.

HOUGH I have not seen any remarks on the subject, I have heard of a literary agitation relative to the procedure of the Council of the Royal Horticultural Society in securing a site for a new national garden. Possibly the notification of Mr. Wilks on page 244 may not be entirely unconnected with such agitation, while some of the allusions of a correspondent on the following page may have reference to the same important matter.

If, as "A. D." appears to suggest, there has been any sort of clamour for the disclosure of propositions and negotiations on the subject of land purchase, or of taking a plebiscite of the Fellows as to diverse lines of action—for diverse they must inevitably be in such a contingency—it is not easy to imagine anything more calculated, if not to defeat, at least to prejudice, the efforts that are being made to do the best that can be done in providing what is needed for meeting the object in view, and at the same time safeguarding the resources of the society.

The Council of the Royal Horticultural Society is elected by the Fellows to initiate the policy and transact the business of the society generally; and in respect to the great change now in progress—a change rendered inevitable in the nature of things—the governing body has been specially authorised to take the necessary steps in accordance with the desire of the Fellows assembled at the general meeting. That the council as an administrative body is acting within its legitimate powers is certain, and great as these powers may be, and serious and far-reaching the action taken or in progress, it can scarcely be less certain that the several members recognise to the full the corresponding magnitude of their responsibility. This being so, they may be trusted to act warily and to consider very seriously every step taken in the execution of the extremely important mission entrusted to their judgment.

To be shackled in the formulation of plans and

No. 2657—VOL. CII., OLD SERIES.

the preparation of a definite proposition would obviously be most disadvantageous, and, in fact, such a great hindrance as to be almost certain to lead to a breakdown; indeed, it is not conceivable that any official body of competent men would consent to act in a case of this nature if they were to be hampered by irresponsible criticism and the inevitable "confusion of tongues."

The present council is composed of distinctly representative men—business men, scientific men, and practical men—of proved administrative ability, with the result that the society is in a more flourishing state than it has been for many years, and enjoys a markedly larger share of public confidence. If such men do not know what is required, and of the means necessary for meeting the requirements, it would be difficult to find any outside body who could be more safely trusted. Yielding to clamour a council once did humiliate itself by the formation of an advisory committee, or something of that kind, to guide it to right decisions, and a few estimable gentlemen enjoyed for a short period the luxury of possessing power without responsibility. It was a lofty exaltation, no doubt, and a distinct novelty. Happily the advisers were not vain, but honestly, if not obscurely, strove to be useful. Still, it is extremely doubtful if the present council will make a similar confession of incapacity. No, it must have the courage of its convictions, disclose its plans when completed, and issue its recommendations; then, if these are rejected, be content with a vote of thanks for its endeavours, and recede into dignified retirement.

The particular site for the new Chiswick must naturally be a question for wonderment. To get beyond the smoke radius, not at the present time only, but for generations to come, the site cannot be within fifteen miles of London. It would not be easy to find a safe from smoke neighbourhood of suitable altitude, good soil, and direct railway connection within that area, so rapidly are building estates being mapped out and covered with dwellings. Besides, just for that reason, the nearer to "town" the more costly the land. The chosen site may therefore be even much farther afield.

We are told by Mr. Wilks that several positions have been inspected, but that one remains to be investigated. As I do not happen to live very far from one particular site I cannot be either blind or deaf to what passes around me. It may not be the one to be eventually selected, but if it should be it will, I am inclined to think, meet "A. D.'s" ideal of a "lovely country, excellent soil, pure air, sunshine, and shelter." To reach this particular rendezvous he would have a quick and pleasant run down, and find it a place in which to spend a "happy day."

Allusion is made to a possible co-operation of county councils in the great undertaking in question. Though the suggestion may not receive unanimous approval, still, on reflection, it is not unlikely to recommend itself to a majority of practical minds. Several county councils are in full sympathy with the work of the society, and some of them give a goodly share of support to horticultural teaching in some of its aspects. The London County Council gives an annual grant for the teaching of vegetable and fruit culture in the pleasure grounds of a London park. It is a curious idea, no doubt, but it shows the desire of the council to be helpful in the direction indicated. It is entirely appropriate that it should be, seeing that London is the greatest consuming centre of garden produce in the world. Nor would it, obviously, be less appropriate for the corresponding authorities in the several counties of supply to share in similar educational work. An arrangement on an equitable basis might be of an enormous advantage to the country, as the greater the means at disposal the greater would be the power for good of a competent administrative body, and this above all others is indisputably the Royal Horticultural Society.

The site referred to would afford scope for establishing the finest horticultural station in Europe. It is hoped "the new Chiswick" will be based on the broadest possible lines, and the procedure in it capable of doing the greatest possible good in various ways to various classes of the community. In a word it should be the recognised seat of national horticulture, and a worthy centenary memorial of the Royal Horticultural Society.—A FELLOW.

Cinerarias.

IN continuation of my subject, of which the opening notes appeared on page 250, I may say that if there be any difficulty in obtaining cuttings, cut down the selected plant after flowering, remove the old soil, place the stool in some shady spot, and cover it with leaf mould; in a few weeks one may expect to find cuttings in abundance. The stool should be saved, all shoots except three or four being taken from it, and straggling roots cut back. Then place the plant in a 5-inch pot, and it will make a fine specimen.

After midsummer, whether the plants are from seeds or cuttings, they should be growing vigorously. Water them cautiously, and when a supply is requisite give a thorough soaking. In my opinion many failures occur through injudicious watering, for though Cinerarias are at this period moisture loving, they are most impatient of an overdose; if the plant is once allowed to become waterlogged, it is a difficult matter to again get it into a healthy state. As Cinerarias are quick growing and free rooting plants they must not be allowed to remain in the pots they now occupy until the roots become matted, or in anything approaching a root-bound state, or they cannot afterwards be induced to progress freely; consequently, when the soil is filled with roots transfer the plants to their flowering pots.

At this final potting some decayed stable manure should be added to the soil, and the pots must be well drained; this is unquestionably a point about which growers cannot be too careful. If it is necessary to use the lights after this potting they should be tilted both back and front, so as to allow the admission of plenty of air, and may be removed at night, as the dews will greatly benefit the plants. Always keep the material damp on which the pots are standing during the summer, and syringe the plants in the afternoon. When the roots have taken properly to the soil, give weak liquid manure at alternate waterings.

In the cultivation of Cinerarias it is necessary all through the several stages of their growth to allow the plants sufficient room to prevent legginess, for should this occur, the large bottom leaves, which add so much to their appearance, and are usually essential to a strong vigorous condition, are sure to die before the time of flowering. Immediately there is any danger of frost the plants must be removed to where it cannot reach them, but they should not, if avoidable, be stood on dry shelves or stages, as they dislike an arid atmosphere. In the event of such being the only position at command it will be found good practice to spread a layer of clean moss on the shelves, as this would do much towards keeping them free from insects, and preserve the lower leaves; or failing this it will be necessary to sprinkle the shelves every morning. If this be carefully attended to there will be little trouble from green fly. In a temperature of about 45° or 50° the most advanced plants will come into flower early in the new year, and those showing a disposition to be later will do with a temperature 5° lower. Growers who have what I should call a retarding house, can do much to lengthen the display from the one sowing.

With regard to insect pests, green fly is undoubtedly very troublesome, but it can easily be exterminated by timely fumigation or vaporisation. The greatest trouble in connection with this pest is when the plants are associated with others in a collection, but like other difficulties it can be overcome. The worst trouble is, in my opinion, the grub of the Marguerite Daisy or Cineraria fly, because it is an unseen enemy and cannot be detected until they have commenced their ravages. The grubs bore their way between the upper and under skins of the leaves, eating the fleshy portion, and thus creating a maplike formation. The best and practically the only way of destroying these grubs is by squeezing them between the thumb and finger. A little practice will soon enable anyone to discover the position occupied by the grub. There seem to be several broods of this pest, and it is therefore particularly desirable to kill the first, or the vitality of the plants will be seriously affected as well as the appearance spoiled. Thrips and red spider are sometimes troublesome, but this should rarely occur if the Cineraria receives the treatment advised.—W. H. DAMERELL.

Odontoglossum elegans Eastwood Park Variety.

AMONGST the most attractive Orchids in the Drill Hall on March 13th was *Odontoglossum elegans* Eastwood Park variety (fig. 70), which was exhibited by Mr. H. Ballantine, gardener to Baron Schröder, The Dell, Egham, who also contributed the typical *O. elegans* for comparison. The Orchid Committee showed its appreciation by recommending a first-class certificate. The flower was better in every respect than the typical form, which, as is well known, came from a cross between *O. Halli* and *O. cirrhosum*, and evidences of both parents were perceptible. The prevailing colour was delicate rose suffused with yellow, and there were numerous large and small chocolate brown spots. This flower was much admired by the visitors on the date named.

Clare Lawn.

DURING the past few years the popularity of Orchids has made very material strides as well in the actual number of collections as in the immense improvements that have been made in existing ones. Throughout the country there appears to have arisen amongst enthusiasts a desire, not perhaps to numerically increase their stocks, but to secure a higher average of quality. They have tried plant after plant, and every one that has been found wanting has had to go, possibly to the home of some younger and less aspiring cultivator. That this fashion—if such it may be termed—will be maintained is more than probable; indeed, the chances are decidedly in favour of its doing so, for Orchids are essentially flowers that grow upon one. The more Orchids anyone sees, the more eager that person becomes to see others, and in this at any rate familiarity does not breed contempt, but rather increased respect. Then, how seldom does one hear of a gentleman giving up Orchid cultivation entirely. Many collections have, it is true, been distributed; but it has almost invariably been by reason of the owner's death.

The love for Orchids has on occasions been termed a "craze," and if the term be accepted then it is a craze to be fostered, for it worships at the shrine of some of the loveliest flowers in the floral kingdom. One may find in the Orchid family every type of beauty, from the most brilliant to the most exquisitely delicate; every form of flower, some quaint, some formal; every habit of plant, including those that luxuriate on pieces of tree stem with others whose wants demand soil of some particular sort. Who would not glory in a "craze" which every year brings fresh beauties and fresh interests? Hybridists, professional and amateur, are ever at their labour of love, and the products of their patient skill are always being sought for. Many never see the outside of the establishment in which they are raised; but when one does come forth that is of superlative excellence what a furore it creates, and how eagerly it is sought by the enthusiasts to enrich their collections. But this is somewhat of a digression.

In the forefront of those whose Orchids have advanced by leaps and bounds stands Sir Frederick Wigan, Bart., Clare Lawn, East Sheen. Here quality has ever been placed before quantity; at the

same time a considerable number of houses are required to find accommodation for the whole collection. Additions are made with steady persistence, but they are largely of something "out of the common." The consequence of this spirit of maintenance is seen in the excellence of the majority of the flowers, and, failing the flowers, the names on the labels tell many a tale. Numerous are the hybrids that have gravitated to Clare Lawn, and have stayed there not to degenerate in health, but to grow and delight their owner and the grower, Mr. W. H. Young.

For some considerable time the writer had looked forward to this second visit to Clare Lawn, and a few days ago an opportunity was promptly seized. It is practically five years since the first journey was made, and much pleasure was derived from it, but more came from that of last week. The general stock shows very evident improvement in condition, this being evidenced in the magnificent leafage of almost every plant, and in the flowers of many of them. The *Phalænopsis*, which have been so remarkably well exhibited at the Drill Hall this season by Sir F. Wigan, were practically over, but their condition spoke volumes for the suitability

of the structure containing them and the treatment to which they are subjected. They are not plants that thrive in every place, but at Clare Lawn they are perfectly at home. The leaves are of wonderful substance, and visitors who saw the flowers at the meetings need no assurance of their excellence. There still remained flowers of *amabilis*, *Boxalli*, *Sanderiana*, and *Luddemania* with one or two others.

One of the most attractive houses is unquestionably the rock fernery, where on bold projections are accommodated huge *Cymbidiums* in pots. These plants amidst the green of the Ferns form a most delightful picture, and one which would elicit admiration from everyone. There are several varieties of *C. Lowianum*, including concolor, and all the plants are in immense pots. The majority of them are producing considerable numbers of spikes, two that were closely observed having fourteen and twelve respectively. The flowers are not yet expanded, but one may easily paint a mind picture of their appearance when at their best. In another house the handsome, though not frequently seen, *Cymbidium*

Hookerianum was flowering, with *C. eburneo-Lowianum*; while in a third structure the chaste *C. eburneum* was producing its fragrant flowers.

As in most Orchid establishments *Odontoglossums* are fairly numerous, but they do not form a feature as is frequently the case. Needless to say there are many species, hybrids and varieties represented from which are obtained spikes of variously coloured and formed flowers. The peculiarly habited *Dendrobium Kingianum* is flowering profusely, as are several *Masdevallias*. Growing in cool quarters are several plants of *Cypripedium bellatulum*. This handsome Orchid is usually found in a much warmer structure, but evidently appreciates its present place. The growth is of course slower than under the customary method of culture, but the leaves are clean and of great stoutness. Needless to say the plants do not get a great amount of water during the winter. The white form, *C. b. album*, is not in the same house, but is given a position in one of decidedly higher temperature.

A singularly beautiful Orchid that one finds under at least two names is *Angraecum modestum*, or, as it is frequently designated, *Sanderianum*. At Clare Lawn both names are represented, and under the former it is at present flowering. The pure white flowers borne on the long spike, as shown in the illustration (fig. 71) on page 263, are most attractive, especially when mentally compared to some

FIG. 70.—ODONTOGLOSSUM ELEGANS EASTWOOD PARK VARIETY.

of the larger flowered *Angræcums*. In the same structure too, was observed *Angræcum* (*Aëranthus*) *Leonis*, whose flowers also are white, but of different form from *A. modestum*, as well as being produced in an entirely dissimilar manner. These are two Orchids that might advantageously be far more frequently seen in good condition. The once comparatively scarce but now extremely plentiful *Dendrobium atro-violaceum* is seen producing numbers of its quaintly formed and coloured flowers. *Vanda gigantea* is not commonly met with in flower, and neither in the habit of the plant nor the beauty of its flowers can anything be found that is probable to bring it into the forefront of popularity.

Dendrobiums barbatulum, *superbum giganteum*, and *Wardianum* play a prominent part in adorning the houses, the last named especially looking particularly handsome. *D. Wiganæ* is not at this moment in flower, but the magnificent growths the several plants are making promise an abundant display of flowers in due season. Like the foregoing, *D. Victoria Regina* is not flowering, but its blue blooms will doubtless come at the proper time. *D. spectabile*, which created quite a mild sensation at the Drill Hall when shown some few months back, is in evidence so far as growth is concerned, as, needless to say, are many others of this charming family. An attractive variety is *D. Sibyl superbum*, whose rose coloured flowers show themselves conspicuously amongst the other occupants of the structure. A plant of Wigan's variety of *Spathoglottis aureo-Veillardii* has been in flower continuously since October, which says much for the attention that is given to the plants. The flowers of *Lælia cinnabarina* are always appreciated in an Orchid house simply because of the distinctness of their colour.

Clare Lawn has been justly famed for its splendid *Cœlogyne pandurata*, which with some growers is decidedly "miffy." Mr. Young has, however, been singularly successful in its culture, and has been able to exhibit to the interested visitor some grand spikes. This year, unfortunately, the plants show signs of failing, and the grower's efforts will have to be concentrated upon them to endeavour to bring them back to the health and strength that have hitherto characterised them. *Tricopilia suavis alba* demands a moment's notice by reason of its boldly handsome flowers: as also does *Epidendrum Stamfordianum*, on account of the peculiar colour of the blooms, and of the habit of producing them. *E. xanthinum* deserves a word in passing, as also *E. Wallisi* and *E. Endresio-Wallisi*, the latter having three distinct sets of growths, each of which is flowering. Numerous bigeners, in the form of *Zygocloax*, find a place, and are apparently in the best of health—indeed, the latter attribute is a feature of nearly the whole of the collection. The hybrid *Phaius Norman* in variety and *Cooksoniæ* are handsome, and find many admirers.

Of the excellence of the collection of *Lælias*, *Cattleyas*, and *Lælicattleyas* it would be impossible to speak too highly. Every effort is made to maintain its standard, and many are the superb forms that it includes. There were not great numbers in flower, but scores of sheaths were readily observable, and will perform their share in beautifying the houses at a later period. One plant of *Cattleya Schröderæ* had fifteen flowering growths, while *C. Trianae* was much in evidence. But it is impossible now to name more of these, or of the many other Orchids that were seen; they must form the theme for a further tale that it is hoped will not take another five years in the telling.—ORACHE.

Freemasonry of Gardening.

(Concluded from page 225.)

SOME delicate matters there are, probably this is one, requiring more subtlety than a gardener's pen is invested with to place them properly on paper, "for many a shaft at random sent finds aim the archer little meant," but the feeling obtains that an opportunity is now offered to do so, as well as some reasons for it. Young travellers, like young gardeners, have something to learn, and possibly a hint may be taken in the spirit in which it is offered and bring them in closer relationship to the great and happy family. In the first place we may take it as an accepted fact that the traveller shows his interest in the welfare of gardeners and gardening by subscribing to the Gardener's Royal Benevolent Institution. That his firm may do so is another matter. It is personal interest which will afford him the opportunity of showing he is desirous of companionship with The Order which means so much to him. Why should he not, also, carry this gospel of benevolence among the heathen—viz., those of little faith, selfish instinct, or whatever deters them from linking themselves to this noble institution? To think of what it is doing for gardeners, and to think of what it might do if every gardener, from the pound-a-week

one upwards, loyally supported, must be the writer's justification for firing another shot into the trenches of prejudice or phlegmatic indifference. Travellers, pray; carry this gospel with you in your wanderings and preach it with all the force of that great eloquence you are especially gifted with.

Most travellers will admit that if they are not always fervently welcomed they are seldom denied common courtesy, though perforce of circumstances the gardener may be placed in he is not only told that gardening is "going to the dogs," but that it has already arrived there. From this canine point of view things are bad, could not, in fact, be worse, but fairly and honestly how do matters really stand? Within a local radius of five miles it is easy to select a dozen gardens which are annually visited by half a dozen representatives of as many firms seeking orders it is utterly out of the gardener's power to give; and still they come; or if occasionally one drops off in disgust a stranger steps into his tracks. Now and again the proprietors of these gardens may give small orders for trees, shrubs, or plants, which the recipients will, perhaps, tell you are comparatively worthless, and which you can well believe, for what are they among so many. Apart from this each place draws its regular supplies from its own particular source, the business being done by post or personally in the shop. All this should account for something in the decadence of gardening from a trade point of view. What a pleasant and goodly thing it is to meet a traveller who values men for what they are and not for what they have! It brings them as once within the charmed circle of the gardener's free-masonry. "I know you cannot now give me an order, but I could not refrain from calling on an old friend for a chat." This is grateful and comforting. Yet, again, there are some in which the commercial spirit enshrouds all else.

Does a gardener ever realise how much he owes to his "Missus?" Possibly not; such things are taken as a matter of course. There is no phase of life in a world of work in which the wholesome influence of man's helpmate permeates with greater force than in gardening, if there are any in which it does so much. Go where you will, or when you will, at the eleventh hour or any other hour, a gardener's friends will find themselves friends of his "Missus;" his work her work, but her work her own. She is a striking though unobtrusive personality in the freemasonry of gardening. Genially sympathetic, eminently hospitable, loyally helpful. Gardeners' visits are not, indeed, like angels' visits; they have a knack of "dropping in" at unpropitious times, or what might be regarded as such elsewhere. "Oh! never mind your boots." The easiest of easy chairs is pulled out, and "What do you think of the Wardianums?" Whilst ever and anon "the Missus" provides a missing word, which neither can think of, and the cheerful chink of china has mingled with words of welcome.

The gregarious instinct of gardeners is a feature with its faults. The "cuckoo gardener," a peculiar variety of the species, appears to be the chief, but not the only culprit in this direction. Until coming within the environs of what for present purposes may be called Suburbia-super-Mare deponent had never heard the appellation, so possibly it is merely local. The "cuckoo gardener," though of the smaller kind, being chiefly single-handed, is one of the best of good fellows, as well as an excellent workman, often producing specimens of culture which would be highly creditable to men and places of higher pretensions. Certainly he is prone to much talking, and thinks no little of himself. Sunday is his great opportunity for visiting, and he makes the most of it. No harm in that. But when represented in flocks, the visit is embarrassing even to "the Missus." So much is this the case that the edict had to go forth, "not at home on Sunday."

A man of mystery may go into the pillory of print without compunction. When first seen he was taken for a gardener, having all the appearance and much of the impedimenta pertaining to the craft, including a goodly houseful of olive branches. He then managed a fairly large garden, and seemed to manage it fairly well. The next time, when seen, he was "out," walking the streets of a big city as an inspector of buildings, he said, when asked what he was doing; a facetious attempt to make the best of a failure. Nothing coming in; all going out; wife and bairns lodged in a back street. Oh, the pity of it! One cannot add much beyond saying, "The quality of mercy is not strained," nor was it then or upon a subsequent application by post, after which he disappeared. Several years after, the wheel of fortune had spun round, and the writer was—well, a bit down, the man of mystery up, when he called in all the glory of five clothes, massive gold chain, and sundry gewgaws disposed about his person. "You don't know me?" "No, sir, you have the

advantage of me." "You recollect so-and-so?" It all came back like a flash. "And where are you gardener now?" "Oh! I've left gardening for good, I'm —, a splendid position. The gentleman who put me on my feet wants some plants, and hearing you were here I thought you would give me some." He was wrong, the superb air of supercilious arrogance accompanying the beggar's petition would have frozen any channel of mercy, and the man of mystery passed out of our garden and our life into another world, between which and the gardeners' freemasonry there is a great gulf fixed.

The gardeners' stock exchange is a prominent feature in the freemasonry of the order. The biggest beggars on earth, they have been called. It seems to be a rule of the fraternity never to visit any

the gardener's pocket in the shape of carriage by post or train. Little amendments are wanted here—in both these phases. "Your gardener has wonderfully improved the place; quite a nice little collection of hardy plants." "Yes; those are G——'s forte." A growl from G—— after the above few words from his master revealed the fact that not a thing had been bought. Love, not money, was forming the collection; and if ever "The Master" gave the matter a thought, it probably went no farther than Topsy's hypothesis of spontaneous generation, "Specs" they "grewed."

In the glamour of the long ago lies some of the happiest recollections of visits paid and received in the little kingdom of bothydom. It was the writer's initiation into the freemasonry of gardening—that

FIG. 71.—ANGRÆCUM MODESTUM. (See page 261.).

place without bringing some bit of the vegetable kingdom back. Bits, scraps, cuttings, eyes, roots; the business done is enormous, the profit to the garden incalculable, although the giving side and the taking side of our ledgers remain evenly balanced. Many lovers of their gardens know this, and enter fully into the spirit of the thing; but others there are, in not understanding may misunderstand, and, consequently, question the sterling honesty of purpose which rules the gardeners' stock exchange. Simply exchange; that "it is more blessed to give than to receive" enters not into the bargain, for, as a matter of fact, pure selfishness prompts the transaction; but it is selfishness in which self is lost sight of in the love which each bears for his own little domain. Services thus mutually rendered are for some inexplicable reason often secret services, whilst most have little sacrifices attached drawn direct from

good camaraderie, which one is never too young to join or too old to enjoy. Well do we recollect that particularly Good Friday, when the lads of — Gardens trooped over to our at home. After a look round, during which our visitors' criticism seemed to amount to everything being just a little better or a little earlier with them, although we beat them by points in exhibits that year, we all adjourned at a given signal for tea—high tea, of course, in spite of the fast day. "Two cups short (a common trick with bothy china) here, a saucer 'll do for you, and I'll put a cork in this flower pot for myself; and, crowning triumph, though unheard of extravagance, a special pot of marmalade, which, to our disgust as hosts, absolutely refused to go round ere the spoon scraped on its thick deceptive bottom. More discussion upon the merits of our respective places and masters, the minstrel following after with such tunes as the punctured bellows of W——'s concertina

would allow. Far, far back; but still the same drama of life, the same scenes, the same loyal sentiments, only young fresh-cheeked actors stepping on and off the boards. God bless them all, and keep them safe within and true to the great brotherhood of love, and work, and duty.—E. K., *Dublin*.

Jottings about Melon Culture.

WELL grown Melons are invariably appreciated by the owners of gardens however small, and in establishments of pretension a regular supply is looked for from May to October, and should any breaks occur their place on the dessert table cannot well be filled with any fruit so showy, or when of high quality so luscious. The majority of gardeners who have the requisite conveniences at command do not often let a break in the supply occur, as they are too much interested in Melon culture, doubtless because the plants give such a bountiful return for the labour bestowed upon them, and during the spring and summer months each day shows considerable progress in luxuriant growth or swelling fruits.

From the end of March onward Melon growing may be termed simple and easy compared with the skilful attention required to produce early crops. When well heated houses—fitted with hot-water pipes for supplying bottom heat—are at command, no fermenting materials will be needed in the beds. The pipes can be covered with a few rough stieks, such as faggot wood, and surfaced with a layer of straw shaken from stable manure. Through these materials the heat passes freely, and thus keeps the soil uniformly warm, there is no sinking of the beds, and the growth from the start is sturdy, though not so rapid as when fermenting materials are employed. The beds in nearly all the Melon houses I have had to deal with have been constructed with the object of leaving plenty of room for fermenting materials, and consequently the pipes were invariably from 2½ to 3 feet below the top of the bed. In such cases when fermenting materials are not employed, the plants must either be planted too far from the glass, or a great depth of rough material used to bring the soil up to the required height, and in the latter instance the plants do not get the full benefit of the bottom heat pipes. In building Melon houses for all crops except the early one, my experience has taught me that the bottom heat pipes should never be more than 18 inches below the surface of the bed; ample room is then left for soil and drainage, the plants get the full benefit of the bottom heat, and are also well up to the light, a combination of advantages which does much toward securing good results.

The compost I find most suitable for Melons is one formed of three parts good loam—rather inclined to be heavy than light—one part fresh horse manure, with a little lime rubble and soot added. These ingredients should be mixed a few days before the Melons are planted. Place a layer of the compost over the drainage (prepared as previously advised), then form mounds for the plants, half a bushel for each is quite enough; I prefer plants in 4-inch pots to larger ones, as they seem to take to the permanent soil so quickly and grow without a check.

Firm planting is of the utmost importance, as it induces sturdy growth and early productiveness; loose planting causes the plants to become very rampant, and the early flowers often fail to set. The old ball ought to be only slightly covered with fresh soil, or decay at the collar will sometimes result. Some cultivators advise that the old ball should under no consideration be covered; but if this is not done, repeated waterings soon bare the roots, and then fresh soil has to be added, and although I have grown Melons on a large scale for years I have never found the plants decay at the collar through giving a slight covering of soil; indeed, it is not usually in the early stages of growth that decay takes place, but rather when the trellis is covered with growth, which prevents direct sunshine from reaching the base of the stems.

When the practice of planting on mounds is adopted I never hesitate to water through a rose quite up to the stems in the early stages of growth; but when the fruits are swelling, especially if dull weather prevails, I am careful to avoid giving water within 2 inches of the stems. Should decay at any time be noticed a mixture of freshly slaked lime and powdered charcoal rubbed on the affected parts will generally arrest its progress. Plants that are short-jointed and hard in the stem do not often decay; it is the soft sappy growth resulting from loose planting and too rich a compost which gives so much trouble in that respect. When the roots reach the sides of the mound a little fresh compost should be added, but I consider it a great mistake to add a large quantity of soil at one time; it is far more satisfactory to perform the work in three stages, and to press the soil firmly at each addition.

In regard to the method of training to adopt I prefer allowing the leader to go unstopped till it is within 2 feet of the top of the trellis, rather than to stop at an earlier stage to secure a few fruits near the base. The plants, under the system I advocate, are thoroughly established in the soil before the strain of rapidly swelling fruit affects them—a matter of great importance in the production of juicy, well-flavoured fruits. Fruits which are allowed to swell before the plants are well established usually have a hard thick rind, and do not develop to a standard size.

The extension system of growing Melons is a good one when well carried out, as the fruits are usually of better flavour than those grown under the ordinary system, as root action is kept vigorous throughout in consequence of continuous growth. The system also allows the cultivator to produce a long succession of Melons from one house. In all stages the growths should be kept regularly thinned and stopped, so that there is no overcrowding of foliage. Those who have not practised this system might think there would be a difficulty in getting successional fruits to swell after the first fruits had taken the lead, but a little observation will soon show anyone how to arrange matters in that respect. When the first fruits are about half-grown they cease to swell for a time while the seed is being formed; that is just the stage at which to set an additional number of flowers. After the whole of the trellis is covered the difficulty seems to disappear altogether, and flowers should be fertilised whenever they show at a convenient point.

Three or four distinct sizes of swelling fruits may often be obtained on a single plant. Some part of such plants needs syringing daily whenever the weather is bright, avoiding portions where the fruit is changing colour, and leaving a chink of air on at the top of the house. When a good number are ripening simultaneously the air should be kept comparatively dry. The fruits do not often crack, as the constant growth generally prevents it, but whenever cracking does take place, if the shoot is cut half through with a knife below the fruit no further trouble is given.

When the crop has been cleared on the lower part of the plants the old leaves should be cut away and young growths tied in. Under both systems of training I like to stop the shoots at one joint beyond the fruit, and then allow the sub-lateral to grow freely for a time.—POMONA.

(To be continued.)

Sweet Pea Bicentenary Celebration.

SUBSTANTIAL progress is being made towards the celebration of the introduction of the Sweet Pea into Great Britain 200 years ago. This celebration, as already announced, is to be held on July 20th and 21st at the Crystal Palace, Sydenham, and will take the form of a grand exhibition of Sweet Peas, shown in bunches, in vases, in pots, in pans, in baskets, in bouquets, in wreaths, in table decorations, and in other ways that may suggest themselves to the gardener and florist; at the same time a conference will be held, at which papers will be read and discussed.

The work of arranging for this conference occupied the attention of the executive committee, which met at the Horticultural Club, Hotel Windsor, on Friday, the 23rd inst., when it was decided that the conference proceedings be held during the afternoon on each of the show days. Broadly speaking, the subjects for consideration upon the first day will be the history of the Sweet Pea, the evolution of the Sweet Pea, also an American's views of this popular annual. On the second day it is proposed to deal with the decorative uses of Sweet Peas, Sweet Pea cultivation, and classification. It is probable, however, that other matters relative to Sweet Peas will be discussed; but a further meeting of the committee will be necessary ere titles and authors can be announced, and the final arrangements made. The desire of the executive body is that the largest possible amount of information regarding Sweet Peas shall be brought into reasonable limits of time and space, for it is hoped that the funds will admit of the publication of the papers read and discussion elicited, together with the classification, in the form of an authoritative report.

The executive committee reports that the actual income up to the date of meeting is, in round figures, £250, including subscriptions and special prizes. The hon. sec., Mr. R. Dean, Ranelagh Road, Ealing, stated that, owing to the increased demand, he had distributed practically the whole of the two editions of schedule and circular, consequently it was decided to have a further 550 of each printed. Letters from several continental and American gentlemen were read, and in each case the writer expressed his sympathy with and interest in the movement, and his intention of being present at the celebration. Mr. N. N. Sherwood's generous offer to place at the service of the committee, for the purposes of classification, the immense trials of Sweet Peas his firm—Messrs. Hurst & Sons—are this season conducting at Kelvedon, was unanimously accepted, and Mr. Sherwood's thoughtful generosity in this matter was heartily applauded.

NOTES & NOTICES

Recent Weather in London.—The weather in the metropolis during the past few days has been characterised by intensely cold winds. On Sunday, Monday, and Tuesday there were occasional snow showers. On Wednesday, at the moment of going to press, it was dull and rather cold.

Weather in the North.—From the 20th to the 22nd cold, dull, drizzly weather prevailed, since which the days have been brighter and dry, with cold easterly and latterly northerly wind. On Monday morning 6° frost were recorded, the third occurrence of frost during the week.—B. D., *S. Perthshire*.

Presentation to Mr. C. E. Wilkins.—Owing to the continued ill-health of his wife Mr. Wilkins has been compelled to leave Swanley, of whose local society he has long been the honorary secretary. At the meeting held a short time back Mr. J. Lonsdale, chairman of the society, presented Mr. Wilkins, on behalf of the members, with a handsome barometer in oak case, bearing a suitable inscription. Mr. Lonsdale, in making the presentation, testified to the ability with which Mr. Wilkins had performed the secretarial duties. Mr. Wilkins acknowledged the presentation in fitting terms.

National Carnation and Picotee Society.—Mr. T. E. Henwood, the honorary secretary of the southern section of this excellent society, favours us with a copy of the schedule of the show to be held at the Crystal Palace on Wednesday, July 25th. As evidence of the flourishing state of the society it may be mentioned that upwards of £300, and silver cups are offered in the fifty classes embodied in the schedule. The exhibition is usually a most interesting one, and the coming event should not prove any exception to this rule. Classes are provided for dressed and undressed blooms; while growers of a comparatively small number of plants will find that their convenience has been studied. Entries must reach Mr. G. Caselton, garden superintendent, Crystal Palace, Sydenham, at least four clear days prior to the date of the show.

Birmingham Gardeners' Association.—An essay on the Carnation was delivered at the last fortnightly meeting by Mr. A. W. Jones, of Handsworth, Birmingham, the well-known and successful exhibitor of the Carnation and Picotee. After prefacing his subject with a few references to the history, popularity, and general usefulness of the Carnation, the essayist gave a thoroughly practical exposition of his own mode of culture, and particularly emphasised the importance of very firmly potting the plants as a means of inducing a substantial growth, and insuring a more uniform state of moisture about the roots. Prior to the delivery of the lecture an interesting discussion took place as to the identity of the real Shamrock, the consensus of opinion being that while the Trefoils (*Trifolium minus* and *repens*) are the more popular emblem, the Wood Sorrel (*Oxalis acetosella*) is the original one.

Meath Agricultural Society.—The first annual meeting of the Co. Meath Agricultural Society was held in the Court House at Navan last week. The chair was occupied by Lieutenant-Colonel Everard; after, the minutes were read by Mr. H. J. Cullen, hon. sec., and signed. The financial report, which was submitted by Messrs. Kean & Co., showed the satisfactory condition the finances were, considering the extra heavy expenditure they had incurred. The chairman, in presenting the statement of accounts, pointed out that their scheme not only included farm produce in its widest application, but also flower displays, and, in order to insure the success of their venture, the committee have decided to add some counter attractions, which would consist of athletic functions. Sir John Dillon, Bart., moved the re-election of the present committee for the ensuing year, and was seconded by Colonel Persteman, and was adopted unanimously. The trustees for the current year will be Simon Morgan, Esq., H.M.L.; Lord Longford, and the Hon. H. Bourke. On the motion of Mr. Dove, seconded by Mr. E. Sclater, that J. L. Naper, Esq., be re-elected president, and was carried without demur. Mr. J. Davis, was appointed assistant secretary, whilst Mr. H. J. Cullen was returned unopposed as secretary.

Hessle Gardeners' Society.—At the above Society's meeting on March 20th, Mr. Lambert of Burton Constable, delivered an able paper on the "Rose, its Cultivation and Progress during the Past Half Century." Some excellent blooms of Fortune's Yellow Rose were contributed by Mr. Lawton of Welton House, who with others vigorously discussed the subject. A hearty vote of thanks to the essayist terminated a highly instructive evening.—J. S. K., *Yorks*

National Auricula and Primula Society.—The annual report of the southern section of this society has now been published, together with the schedule of prizes for the show, to be held in conjunction with the Royal Horticultural Society at the Drill Hall on April 24th. From the committee's report and the balance sheet it may be gathered that the society's affairs are quite satisfactory. The schedule embodies thirty classes, and every endeavour has apparently been made to meet the requirements of all classes of cultivators. The hon. secretary is Mr. T. E. Henwood, Auricula Villa, Hamilton Road, Reading, from whom schedules and all necessary particulars may be had.

Chester Paxton Society.—The annual exhibition of this excellent society, which by its periodical meetings is doing such thoroughly good work in increasing the interest in horticulture, is announced for Tuesday and Wednesday, November 13th and 14th, in the Town Hall. The schedule includes about six dozen classes, of which upwards of fifty are devoted to fruits and the remainder to Chrysanthemums. There are sections divided by certain rules, which, with the instructions to exhibitors, are given in clear, concise language that practically precludes the possibility of errors. The honorary secretary is Mr. G. P. Miln, Grosvenor Museum, Chester, who will furnish all requisite information.

The Horticultural Society of Ireland.—At a recent meeting of the members of the above society, held in their offices at 61, Dawson Street, there was a large attendance of members present. After the usual preliminary business was transacted, Mr. F. W. Moore proposed the following motion:—"That a list of meetings attended by each member during the coming year should be printed," a motion which gave rise to a warm discussion; ultimately, however, Mr. Moore, by his wonted energy, carried his motion safely through. There was also a discussion relative to presenting an address to her Most Gracious Majesty the Queen; also the allocation of funds for especial decoration of their first floral display for 1900 if needed. Both these motions were agreed to without any voice of dissent. After the final preparations for the spring show, to be held on the 11th of April in the spacious buildings at Earlsfort Terrace—namely, the Royal University Buildings—were arranged, the business of the council was brought to a conclusion. Mr. W. H. Hillyard, secretary, was in attendance.

Isle of Wight Horticultural Society.—The programme of this excellent association includes:—April 4th, Town Hall, Cowes, "Bees and Bee-keeping," by Mr. F. Midlane; 7th, The Institute, Shanklin, "Notes on Grape-growing," by Mr. J. G. Walker; and the Guildhall, Newport, "The Value of Gardening as a Means of Education," by Mr. T. G. Roper, M.A., H.M.I.S.; 19th, Town Hall, Ryde, Daffodil and Spring Show, in conjunction with the Ryde Horticultural Society. May 5th, St. George's Hall, Sandown, "Flowering and Ornamental Foliage Creepers for the Embellishment of House and Garden," by Mr. Cor. Orchard, F.R.H.S.; 19th, The Mission Room, Brading, "Bees and Bee-keeping," by Mr. J. Newnham; 24th and 25th, Inner Temple Gardens, London, Excursion to the Great Temple Show. June 2nd, Warburton's Hotel, Newport, "Tomatoes, Inside and Out," by Mr. H. Sickelmore; 16th, Schoolroom, Wroxall, "Bees and Bee-keeping," by Mr. T. Collister. July 7th, Warburton's Hotel, Newport, "Plant Foods," with chemical experiments, by Mr. A. Key, M.A., H.M.I.S.; 20th and 21st, Crystal Palace, London, excursion to the Great Sweet Pea Show—the bi-centenary of the Sweet Pea; 14th, Literary Institute, Ventnor, "Bees and Bee-keeping," by Mr. F. Midlane. August 4th, Warburton's Hotel, Newport, "Cultivation of Bulbs," by Mr. J. Hygate; 18th, Schoolroom, Yarmouth, "Bees and Bee-keeping," by Mr. F. D. Hills. September 1st, Town Hall, Ryde, "Australian Fruit Culture," by Mr. G. J. Grapes; 15th, Mission Room, Freshwater, "Bees and Bee-keeping," by Rev. R. L. Morris, M.A. October 4th, Medina Hall, Newport, Fruit and Honey Exhibition. November 3rd, The Literary Institute, Ventnor, "Chemical Manures," by Mr. F. W. Shrivell. December 1st, Warburton's Hotel, Newport, "Bedding Arrangements," by Mr. W. Tribbick.

Gardening Appointments.—Mr. M. Costello, late gardener to Sir James Talbot Power, Bart., Edermine, Enniscorthy, has been appointed head gardener to Lady Ffrench, Elm Park, Merrion, Dublin. Mr. D. Anderson, formerly head gardener at Monkstown Park, has been appointed to a similar position in the gardens of Mrs. Pease at Willow Park, Booterstown, Dublin.

The Shamrock.—At a meeting of the Royal Botanic Society of London on Saturday, the secretary, Mr. J. B. Sowerby, made some remarks upon the species of plants known as the Irish Shamrock. He believed no particular plant had been generally accepted, but the Clover most common in each district was so regarded by the inhabitants. It was usual to think that the white Clover (*Trifolium repens*) was the true plant, but many well known botanists believed that the Wood Sorrel (*Oxalis acetosella*) possesses the best claim to the title. This view was also held by several deceased scientists.

Reading Gardeners' Society.—A large attendance of members assembled on Monday last in the Club Room of the Old Abbey Restaurant to spend an evening in "A Surrey Garden," by the aid of limelight views, and under the guidance of Mr. Alex. Wright of Bucklebury Place Gardens. The garden was that of Falkland Park, which was entirely planned and managed for several years by Mr. Wright, who in a very interesting manner explained the different alterations that were made and the reasons for planting particular varieties of trees, shrubs, and flowers. Messrs. Baskett and Neve spoke to the very interesting evening that had been spent, and congratulated Mr. Wright on the splendid way in which he had laid out the grounds and gardens under his charge. On the proposition of the chairman, Mr. E. Fry, a hearty vote of thanks was accorded to the lecturer, and to Mr. G. Smith of Cintra Lodge Gardens for staging some beautiful specimens of the white Grape Hyacinth, and to Mr. Cretchley, The Gardens, The Honeys, Twyford, for a splendid plant of *Cineraria stellata*.

Royal Meteorological Society.—The monthly meeting of this society was held on Wednesday evening, the 21st inst., at the Institution of Civil Engineers, Great George Street, Westminster; Dr. C. Theodore Williams, president, in the chair. Reference was made to the loss which the society had sustained by the death of Mr. G. J. Symons, F.R.S., who had held the office of secretary from 1873 to 1899, except for the two years 1880-81, when he was president. At the annual meeting, on January 17th last, he was elected president for the second time, in order to preside over the jubilee celebrations of the society next month. Owing to being seized with paralysis on February 14th he had to resign the presidency, and as he never rallied he died on the 10th inst. A vote of condolence with his relatives was passed by the meeting. Twenty-seven new Fellows were elected, as well as two honorary members—viz., Mons. Albert Lancaster, director of the Belgian Meteorological Service, Brussels; and Gen. M. A. Rykatcheff, director of the Central Physical Observatory, St. Petersburg. The following papers were read:—"The Ether Sunshine Recorder," by Mr. W. H. Dines, B.A.; "Remarks on the Weather Conditions of the Steamship Track Between Fiji and Hawaii," by Capt. M. W. C. Hepworth; and "Comparison by Means of Dots," by Mr. A. B. MacDowall, M.A.

Bulb Exporters' Association.—We learn that an association under the above style has been formed by the bulb exporters of Holland in order to protect their mutual trade interests. A status inquiries department, and another for the collection of debts, are special features. The managing director of both these departments is Dr. J. Spoor, solicitor, by the Haarlem court of justice, who acts also as a secretary to the association. The association is divided into six sections according to the principal countries where bulbs are being exported to—viz.: 1, United States of America with Canada; 2, Great Britain and Ireland; 3, Germany and Austria; 4, France and other French-speaking countries; 5, Russia; 6, Scandinavia and Denmark. Each section has its own committee of management: the United States section being a continuation of the late exporters' bond at Lisse. The sectional presidents represent their sections in the general committee. Mr. T. van Waveren is elected president, Mr. Ernst H. Krelage vice-president, and Mr. J. H. Wentholt treasurer. The association, which was started in February, now already consists of 115 sectional members. The headquarters of the association are at Haarlem, and all correspondence should be addressed to Mr. J. Spoor, Wilhelmina Straat 24, Haarlem.

The Foreign Apple Trade.—This continues large in volume, but the season's business to date has averaged only fairly satisfactory. This is true of shipping interests in the U.S. and Canada, and of receivers at London, Liverpool, and on the continent. Much of the trouble may be summed up in the old story of undesirable fruit and unsatisfactory packing. The goods too often arrive at the auction rooms in disappointing condition. Prices received are low, and there is loss for the American shipper. Some of the trade papers are this winter advocating a change in the "machinery," and believe the time will come when foreign dealers will buy direct on this side the ocean from local agents. This will insure proper selection of fruit and proper packing. During the present season, especially throughout the autumn months, too much fruit of soft varieties was sent abroad, tending to demoralise the trade.—("American Agriculturist.")

Flowers Grown by London Children.—An effort to encourage London children to cultivate flower growing has met with gratifying results in the parish of All Saints, South Lambeth. By the kindness of Mr. A. Cameron Corbett, M.P., 2000 poor children were presented each with a Hyacinth bulb and a glass in December last, with simple instructions for growing. A Hyacinth show was recently held at All Saints' Institute, and a beautiful display of flowers was the result of the children's efforts. When it is remembered that they were grown in some of the poorest houses in the vicinity of Nine Elms, Wandsworth Road, and in rooms where a large number of persons have to reside and sleep, it was astonishing that such good results were produced. The vicar, Canon Allen Edwards, presided, and Mr. Corbett gave away prizes which he had provided for the best productions.

Agitation Against Poisonous Compounds Act.—A society has been formed under the title of the Traders in Poisonous Compounds for Technical or Trade Purposes Protection Society to secure the amendment of the Pharmacy Act of 1868, whereby it may be made legal for traders other than pharmacists to sell poisons and poisonous compounds for technical or trade purposes. The initial meeting was held on December 6th, 1899, at Euston Hotel, London, where a number of influential firms were represented, and it was resolved that the existing unsatisfactory conditions of the Pharmacy Act of 1868, whereby poisonous compounds can only be sold legally by chemists, should be ventilated in the agricultural and horticultural and seed trade papers. A second meeting was held on the 6th inst., at Euston Hotel, when it was resolved to extend the sphere of this society to all those trades who are in any way affected by the existing Pharmacy Act, and who would be benefited by an amendment of the said Act to enable them to retail poisons or poisonous compounds for any technical or trade purpose, in original sealed packages, as received from the wholesale dealer or manufacturer. A committee has been nominated, with power to add to their number, who have appointed Mr. G. H. Richards, of 128, Southwark Street, London, S.E., as treasurer; and Messrs. Dobbs & Hill, of Worcester, as legal advisers. Offices and a permanent secretary will be appointed, and to meet expenses it will be necessary to obtain subscriptions. Among the gentlemen present at the last meeting there were guarantees given amounting to £150. The minimum subscription for membership has been fixed at 5s. per annum, or a donation of 10s. 6d.

A dull week with cold winds and scarcely any sun. Rain fell on three days.

Pelargoniums and Geraniums.

COINCIDENT with the floricultural attributes of the late Mr. E. J. Lowe of Highfield, Nottingham, I am reminded of an article by Mr. J. R. Pearson, Chilwell, upon this subject, published in the *Journal of Horticulture*, November 12th, 1874, to the effect that Mr. Lowe had succeeded in crossing Madame Vaucher zonal Pelargonium and Geranium sanguineum. Many of the seedlings produced red, rose, and white flowers, some with curious foliage. Mr. Lowe sent him two plants in flower, much alike in every respect, and they strongly evidenced their parentage. The colour of the flowers was lilac pink (some see blue in them), and the shape of the flowers was the exact opposite of what a florist would consider perfection, the petals being long and narrow. Mr. Lowe thought it a mule, but Mr. Pearson opined that he would be able to seed it. Mr. Pearson intimated that at the first opportunity he would take one of the plants to the Pelargonium Society's first show, so that the opinions of the savants might be gleaned. I do not, however, recollect having learnt more about the plants since then, and it would be interesting if Mr. Chas. Pearson or other authority could furnish further information anent those botanical curiosities.—W. G.

Sizes of Leeks.

IF, as I gather from the paragraph on page 197 in relation to this subject, it is held that we here in the south do not grow Leeks equal to those produced in Scotland, I cannot but recall the fact that when Messrs. Dobbie & Sons held their great vegetable competition at the Royal Aquarium a few years since, the show of Leeks being the most extensive and remarkable ever seen in the south, and included many samples from Scotland, that the first prize for the finest half dozen was awarded to samples from Hackwood Park, Hants. If, as I gather, the largest of Scotch-grown Leeks measured 8 inches in circumference, then they must have been coarse and huge indeed. A really fine stem is only 4 inches in circumference, and many that take prizes are less in circumference than that, but have from 12 to 14 inches of stem clean blanched.

It is, however, assumed that Leeks are grown for consumption as well as for show, and I am certain that stems only 3 inches round would, when cooked, be found far more pleasant eating than those 6 or 8 inches round. In the Onion we find that size seems, when the bulbs are well grown, to induce nothing coarse in the flesh; but with the Leek, the larger and thicker the many layers of flesh formed in the stem the harder and coarser they are. It is very easy to understand that there are districts where size seems to be the chief consideration. We have quite enough of that form of estimation in the south not to be able to throw stones at the north. Universally it is desirable that table excellence should have full consideration in all vegetable judging.—A. D.

Sparrows and Crocuses.

YOUR correspondent "A. D." is evidently a sweetly reasonable sort of man, also modest, though, perhaps, not overwhelmingly so. He seems to like thinking and setting down his thoughts, and I am one of the last of those who would wish him to do otherwise. There is a certain freshness about his jottings, and no one can say he has a dull pen. But to the Crocuses. "A. D." (page 249) prefers to think "that sparrows mutilate the flowers of yellow Crocuses because they find something sweet in them, and that their act is not 'wanton.'" He is quite entitled to think so; but why should he object to others thinking differently if they are so impelled? He says whoever may give a reason for the practice "must give a practical one," mere assumption (of the nature of his own) "will not do." This is a little curious, but there it is.

I have a mixture of variously coloured Crocuses. The rascally sparrows touch none but the yellows, and these they appear to delight in mutilating. As birds and flowers are convenient for examination, and as I must not say the sparrows are "wanton" and their motive destructive, I "prefer to think" they act in a spirit of sport or spite, for so far as I can see they eat not a particle of the flowers they spoil. It may be there is something in them of which a small amount goes a long way, hence "little nips" suffice. This is suggestive of a bad habit, and I certainly regard the habits of the birds as very bad, for they ruin my yellow Crocuses without benefiting themselves. I have sometimes wondered if they caught a passing reflection of their perky little selves in the glistening flowers, and thinking it a stranger, gave it one of their nasty little pecks. This is the only approach to a "reason" that I can give. True, it is not very "practical," being only on a par in that respect with the theory of "A. D."—B. K., Croydon.

Primula kewensis.

Two years ago this new Primula, which was awarded a first-class certificate by the Floral Committee of the R.H.S. on February 27th, originated among a number of seedlings of *P. floribunda* at Kew. It is of hybrid origin, *P. verticillata* and *P. floribunda* being the parents. These two species are generally associated with each other in the greenhouse, and by this means became crossed. When in a young state the hybrid was seen to be much more vigorous than the young plants of *floribunda*, and eventually took a considerable degree of the habit of the other parent, the leaves, however, being free, or almost so, of the white colouring of *verticillata*. The plant exhibited was a foot through, and rather more than that in height, and was a perfect mass of flower stems, on which the whorls of bright yellow blossoms are abundantly produced. The habit is all that is good, the flower stems being strong enough to support the mass of bloom without being at all stiff. It has yet to be seen whether it can be reproduced from seed; if this can be done it will make a thoroughly good greenhouse plant, as the same plant can be had in flower for several months. Despite "Scrutator's" assertion on page 199, I think this is undoubtedly a true hybrid, though it was not secured artificially.—R. G. K.

Judges and Judging.

By way of showing that there is room for differences of opinion to exist, and to illustrate how conscientious our best judges are, and how much trouble they take to arrive at the best decisions, I will, if you will permit me, recall an incident which occurred at one of our great provincial shows a few years ago—an incident honourable to all who took part in it. A valuable prize was offered for a large group of Sweet Peas. The two judges who were appointed to judge the class were a well-known florist and a representative of the horticultural Press—two men whose ability for the work could not be called in question. Well, they differed in opinion, and called in other two judges, one being one of the first gardeners in the kingdom, and the other a well-known commercial horticulturist, recently deceased. These two gentlemen again divided, so that there were two for one stand and two for another. To bring matters to a climax a fifth judge was called, and he happened to be perhaps the foremost authority on florists' flowers in Britain. His vote, of course, settled the matter. It is perhaps worth while pointing out that the society at whose show this incident happened adopt the course advocated by "An Old Provincial," as the same judges are appointed to do the same work year after year.—OBSERVER.

Bud-dropping in Peaches.

THE interesting note by "W. S.," on page 172, respecting this troublesome habit of Peach and Nectarine trees will repay perusal by anyone who grows these delicious fruits. Evidently "W. S." has had far too much experience to start a direct theory as to the cause of bud-dropping, and he is careful to show that one at least of the accepted causes has not in his case been followed with such disastrous results as he expected. But he wisely refrains from concluding that dry roots and red spider do not form a combination likely to result in bud-dropping.

Circumstances so alter cases that the more experience one gets in this, as in other branches of gardening, the less one is likely to commit themselves. But after all the thing has to be looked at squarely, and those who have to provide fruit for dessert must strain a point to do so, let bud-dropping be never so mysterious, and mysterious it certainly is. In my own case I have to provide fruit at a season that necessitates forcing that very early variety Waterloo, but the demand is not great, and one tree of it suffices. This, of course, has to be grown in a house with later varieties.

In the summer of 1898 I was convinced that this individual tree had its wood over-ripened, and I found to my cost that it was so, for though carefully looked after as regards watering at the roots, bud-dropping was so badly in evidence the following winter that a partial crop was all I got from it. Last summer the tree was shaded as soon after the crop was gathered as seemed desirable, and this season it is carrying a crop that will have to be thinned to at least a third of the number now swelling.

Other trees in the house are Early Grosse Mignonne and Alexandra Noblesse. The latter was carrying its fruit last season, and wanting a dish in July I had perforce to shade it to keep it back. This has suffered from bud-dropping a little this year, so it would appear that shading in one season and in trees next to each other led to entirely different results. Here of course the man with a theory—if he was sufficiently acquainted with varieties—would say that Waterloo naturally made up its growth earlier than Alexandra Noblesse, and therefore required shading, while the latter would need all the light available.

This is just what I thought at first, but the other tree, Early Grosse Mignonne, is in the lightest part of the house, was totally unshaded all through the season, and is now the most satisfactory of the three, and as all acquainted with it are aware, it is a variety that brings its growth

early to maturity. When we start out with the idea that over-ripening is the cause of the trouble, we are met with the significant fact that the highest and best ripened portion of the trees are least affected. "W. S." has shown that in his case at any rate his trees have been comparatively immune through the dry season, and want of water should by all reasonable deduction have produced one of the worst seasons on record.

Yet with all this seemingly contradictory evidence there can, I think, be little doubt that the more carefully the trees are cultivated and the closer the attention paid to the likes and dislikes of individual sorts the less likely is bud-dropping to be a serious trouble. Therefore avoid overcropping and starvation as much as overfeeding with its attendant grossness of growth. Avoid, too, the slopping about of pailfuls of water early in the season and the drenching two or three times daily with the syringe whether the weather is fine or wet. Lay in only sufficient wood to form a well furnished tree, so that the light plays as equally as possible in all parts of it, and keep the foliage clean.

This advice has been given many times in the Journal, but unfortunately it is not often followed in its entirety. Again I would like to see those practical men whom one often meets at shows and in their gardens, coming out of their shell and letting readers have the benefit of their own experience.—H. R., *Coldham Hall, Bury St. Edmunds.*

Market Gardening in South Africa.

THE market gardener is to a considerable extent a yet unknown quantity in South Africa. In the Transvaal this is especially the case. There has always been a good market for all kinds of garden produce in Johannesburg, but the demand has invariably been greater than the supply. The same remark applies to most of the towns and villages in South Africa, with the exception of Cape Town, and here vegetables such as Cabbage, Peas, Beans, and Tomatoes can be obtained at reasonable prices. In Natal the "market gardens" are almost entirely in the hands of the coolies. These people were originally brought over from India under indentures to work on the railways for a certain number of years.

After their period of service expired they took up plots on the land between Durban and Pietermaritzburg. They have turned their attention principally to fruit and keep the market well supplied with Bananas and Pine Apples, which can generally be bought at the rate of 2s. per 100 for the former, and six for a shilling of the latter. They are not market gardeners in reality, though they are called so. Chinamen are popularly supposed to be excellent market gardeners, at least this is the opinion held in Australia and the Pacific coast. Some of these people have at times settled down in the Colonies and started gardens, but Europeans in Africa will have no dealings with them, and they have had to turn their attention to trading with the natives.

The Boers as a rule live on Pumpkins. This is their one vegetable food. Pumpkins are no trouble to grow, they are also no trouble to prepare for the table, and it is hard to enter a Boer homestead at the dinner hour without finding this vegetable on the table. Pumpkin is very well in its way, but Englishmen soon tire of it and look for others, which as a rule they cannot get. On the mines along the Witwatersrand reef the great difficulty the men had to contend with was the absence of all green food. Many of these mines employed as many as five or six hundred Europeans, and it is not going beyond the mark to say that the white men on the reef would have disposed of enough garden produce to have kept dozens of gardeners busy, but no attempt was ever made to supply them. The writer lived on one occasion for about a year on a mine situated about ten miles from Johannesburg, and during that period the only vegetable he partook of, leaving the inevitable Pumpkin on one side, were of the potted variety.

After the present "difficulty" is satisfactorily settled, there will be great openings for qualified market gardeners in Africa. The climate is all that could be desired. Labour is cheap, natives can be engaged to work for 15s. a month, and their food; the latter consisting of maize with an occasional supply of meat, costs very little. With a growing population, ever increasing markets will be opening up in all the large towns and villages of the colonies and the Transvaal. A few years ago an expert travelled through the country districts of the Cape and Natal giving lectures on dairy farming. This gentleman was despatched on this errand by the Government, and the farmers came in in numbers to listen to him and to ask his advice, since which a great improvement in the supply of dairy produce has been noticeable. The market gardener, however, has been altogether neglected.—D. G. R.

[It is certain that the opinion expressed above will be justified by the development of a market gardening industry in the neighbourhood intervening between Johannesburg and Pretoria, which lie some fifty miles apart. There the marvels witnessed at Melbourne and San

Francisco during the second decade of their existence—1860-1870—are sure of being reproduced, so that ten years hence a population of some two hundred thousand or more will be crying for fresh vegetable food during the summer months. The demand for Peas, Cauliflowers, Cabbages, Tomatoes, Melons, Potatoes and Brussels Sprouts will be enormous. But intending emigrants should recollect that, compared with England, it is an arid land, and the soil can only be kept moist and friable during the winter and spring months by continual watering or even irrigation, if good results in market garden produce are to be obtained. Then with the summer come swamping thunderstorms and often astounding hailstorms, which destroy unprotected vegetables and fruits.

Hence the newcomer must have a little capital if he wishes to secure the first fruits of the new condition of things. So wonderful, however, are the productive properties of the soil when plentifully irrigated, that a skilful cultivator will rapidly reap the reward of his labours in the matter of produce, while for the first half a dozen years prices will undoubtedly rule high. It may be said that in mining communities market gardening is the one industry which is not overdone. Moreover, the Rand is not in the nature of a precarious alluvial mining camp, but a centre of solid wealth, which will attract the class of luxurious persons who consume fresh food in large quantities. Pastoral farmers like the Boers and isolated miners gradually learn to dispense with fresh butter, cream, milk, and vegetables. In countries such as Australia and South Africa there is no verdant landscape or dairy farming scenery, and "a farm" is the last place at which to procure the aforesaid necessities of European life. These things are only developed within easy distance of the most populous districts—one of which the Rand is certain to become.]

Spring Flowers.

To many persons the spring of the year is the most pleasing of all the seasons, and one can scarcely be surprised that this is the case. The lover of Nature, the lover of flowers, the lover of trees has then the opportunity of seeing all these things clothed in their tenderest garb, which appeals to them more than the profusion of summer or the rich full tones of the autumn colours. There are few gardens indeed where the spring does not bring in addition to its bountiful promises a certain number of flowers, and there are none at any period of the year or in any position in the garden that are more beautiful than these. They are not as a rule of pretentious charms, but tend rather to a purity and modesty that appeal with irresistible force to the tastes of the refined.

Where is the gardener, be he amateur or professional, who does not delight in wandering round his garden, peering into nooks and corners for the anticipated flowers? The garden may be simply a narrow straight border in a confined back yard, or the gardens and grounds of some princely domain; in both are the same keen desire, the same eagerness, to find first the harbingers of spring and then the blossoms, telling us in floral language that spring has come. Hundreds of thousands of flowers are thus sought for by those interested in horticulture throughout the length and breadth of the British Isles.

Our pleasure in this pursuit is added to immensely by the vagaries of the climate, with its many rapid changes, that carry us from sunshine to gloom, from calm to storm in the space of a few short hours. Every gardener knows that we scarcely have two seasons alike, whereas in many other lands the seasons come and go with the regularity of the tides, and each succeeding one is largely a counterpart of its corresponding predecessor. Though these extreme variations cause us many an hour of trouble, they nevertheless add a meed to our enjoyment in bringing us constant surprises, for to a great extent we never know what the next day may bring forth. We find the swelling bud, and speculate as to its complete expansion, but our estimate is not always correct. We have all seen the bud that wants the sun's genial influence for only a few hours' rest in the same condition for day after day, and almost week after week. By this very uncertainty, then, I say again, is added a zest to our appreciation, and a greater power to enjoy our treasures when they come. We Englishmen can yield to none in our power to appreciate the beauties of Nature as found in the field, the hedgerow, the garden, and the wood.

If the enthusiastic hardy plant lover could in a few days during spring visit different places in the British Isles, with their varied conditions, what a plethora of beauty he would find. Plants that in

northern and cold exposed places have scarcely started to grow would be found in their glory in some genial southern spots, and those which had gone past in the latter would be at perfection in the former. Even in very limited areas the difference of the precise moment of flowering varies considerably, so that neighbours within easy distance can admire the plants in each other's garden over a much more protracted period than could possibly be done in their own.

course to think of summer and autumn glories, and must not completely fill the whole of the available space in the garden with early flowers, and thus preclude the possibility of finding places for plants that bloom later in the year.

The simple flowers of the spring, such as the Snowdrop, the Violet, and the Crocus, wake an enthusiasm which the Rose in her season is scarcely capable of excelling, and cultivators are watching each morning

FIG. 72.—SPRING FLOWERS.

What a wonderful list the expert hardy plantsman could compile if he were to set himself to the task of enumerating only the choicest spring flowers! The range of shape of flower, habits of plants, dates of blooming, and colour would be enormous, and the fortunate possessor of such a stock would constantly revel in the prodigality of beauty in his garden. But such is scarcely possible, though there are many amateur specialists who have marvellous collections. They have of

these chaste and simple flowers developing in the growing sunshine. Look at those represented in the illustration (fig. 72), which include the Snowdrop, the Crocus, and the Oriental Hellebore; or, as the latter is often popularly termed, the Easter Lily. In form it can scarcely be regarded as resembling the Lily, with which it has not the slightest relationship, and inasmuch as the variety represented is atropurpureus, the resemblance is still further decreased. The particular Snowdrop

depicted is *Galanthus Imperati*; while the striped *Crocus* is Sir Walter Scott and the self David Rizzio.

There are portrayed three of the flowers of the day; more might have been added, but the individual beauty would have been much reduced if not entirely marred by doing so. There is one great point in favour of these and kindred vernal flowers—namely, that they will grow practically anywhere, and it is almost certain that a selection might be made which would thrive in any reasonable position. They do not call for large outlays of time or of money, and consequently are amongst those plants that come into the small as well as the large garden, and flourish and give pleasure equally in both.—H. ROSE.

The late Mr. G. J. Symons, F.R.S.

FEW readers of the *Journal of Horticulture* can, I think, have failed to consult at some time or another the excellent little weather table which until recently appeared weekly in its pages, signed G. J. Symons. The first of these weather reports made its appearance as far back as July, 1870, and the series only came to an end in July last year. Is there a single writer for the *Journal*, I wonder, who has ever equalled this record as a contributor week by week without a break for nearly thirty years. But, then, a very brief glance at his lifework will, I feel sure, be sufficient to show that the late Mr. Symons was no ordinary man.

His career as a meteorologist may be said to have begun when at the age of nineteen he started an organisation for observing and recording thunderstorms. Three years later he entered upon the great work of his life, when he published the first volume of "British Rainfall," containing the returns from 168 stations in the British Isles. During the present year will appear the fortieth volume of that valuable annual, under the editorship of his appointed successor, Mr. H. Sowerby Wallis, who has for nearly thirty years assisted him in this unrivalled piece of rainfall work. To show how this rainfall organisation has increased and expanded, I may state that in the new volume when it comes out will be found classified, discussed, and arranged in the most exhaustive manner, the records from over 3000 observers. In 1866, or six years later, Mr. Symons started his "Monthly Meteorological Magazine," the last number of which, and the only one which has not contained a contribution from his pen, reached me about a week ago. Consequently this, the only magazine in this country devoted exclusively to the science of meteorology, has been in existence for over thirty years.

In 1856 he joined the British (now the Royal) Meteorological Society, which the late Mr. E. J. Lowe, F.R.S., whose death we have also to deplore, had assisted in founding only six years previously. For forty-four years Mr. Symons was a Fellow of that society, and for twenty-five years one of its secretaries. For forty-two years, Mr. Wallis informs us, he supplied monthly records of meteorological observations to the Registrar-General; for forty years he was a member of the general committee of the British Association, and served on many of its committees, and for nearly forty years he was a member of the Scottish Meteorological Society. For twenty-seven years he was a member of the Société Météorologique de France, and served three times on the Council. Added to all this, throughout the forty years in question he kept continuous records of atmospheric pressure, temperature, and rainfall in Camden Square, and it was from these observations that the weekly weather tables in the *Journal of Horticulture*, before referred to, were compiled.

Then as regards honours, it will suffice to mention that he was elected a Fellow of the Royal Society in 1878, that he was created a Chevalier de la Légion d'Honneur in 1891, and was selected by the Prince of Wales to receive the Albert medal of the Society of Arts for 1897. He was president of the Royal Meteorological Society in 1880 and 1881, and in view of the approaching commemoration of the society early next month of its fiftieth year, he was re-elected president only two months ago for that year. This is the first instance in the annals of the society of the re-election of any president after having once held that office for the usual term of two years. From the foregoing slight sketch it will be gathered that the subject of this brief memorial notice was not only an eminent meteorologist, but also a most indefatigable and earnest worker.

But how can I hope to convey to those of your readers who did not know him as intimately as I had the honour and pleasure of doing for over twenty-five years the wonderful charm of his individuality? Although always busy, his usual hours of work being from 9 A.M. until 11 P.M., he was ever ready to lend a helping hand to any fellow meteorologist requiring it. It has often been said of some great man who has passed away—

'He was a man, take him for all in all,
I shall not look upon his like again.'

Never I think were these words more appropriate than in the case of Mr. Symons—the best known and best beloved British meteorologist of his day. Nor can we wonder that our loss should be thus irreparable

when we consider that for over forty years he had been carefully training himself for one special line of work, a line of work for which, owing to his genius for statistics, his powers of organisation, and his genial temperament, he was peculiarly fitted.

Whether in his study, in his matchless library of meteorological works, at a council table, at a public meeting, in the house of a friend, or wherever he went, there was always a certain indescribable charm of manner and of speech which rendered him a general favourite. Although such a book lover he was not the least a pedant. Indeed, his conversation and writings were invariably characterised by their unpretentiousness, ready wit, and clearness and conciseness of expression.

Although for some years on the council of the Royal Botanic Society, he was no horticulturist; and yet in hundreds, if not in thousands, of gardens throughout the length and breadth of the land the name of Symons has become a household word, owing to the numerous rain gauges he has from time to time been the means of establishing all over the country.—E. M., *Berkhamsted*.

Notes on Figs.

THE fruits of Early Violet and St. John's ripen on trees started in November or early in December during April, or under hard forcing in March, and though small are desirable for early dishes. Angelique, Brown Ischia, Pingo de Mel, and White Ischia are also excellent for early forcing in pots, the fruits being wholesome, and much appreciated at table. All points considered, Brown Turkey is the best Fig for general cultivation, forcing well and bearing abundantly. A good companion for it is White Marseilles.

When ripening commences the atmospheric moisture should be gradually reduced, admitting a little air constantly by the top ventilators, as a circulation of rather warmer and drier air is necessary for securing flavour and thorough ripening, and also for avoiding "spot." The fruits of the later varieties are particularly liable to this defect due to a parasitic fungus, *Gloeosporium læticolor*, which is best guarded against by a little sulphur on the hot-water pipes, withholding water from the fruit and ventilating freely. It is also advisable to gradually reduce the supply of water to the roots when the fruit commences ripening, yet affording sufficient to keep the foliage healthy. The combined conditions appear to baffle the fungus, and favour high quality and good finish in the fruits.

Early forced planted out trees appear to swell and retain their first and most valuable crop when the growths are kept somewhat closely pinched in the early stages, the principle being that the energies are concentrated on the fruit, instead of being drawn away by allowing the growths to extend considerably. In some cases pinching to three leaves has the effect of causing the first crop Figs to swell and pass the flowering satisfactorily, whilst other trees allowed to make five or six leaves before pinching off the points of the shoots cast the fruit wholesale.

These are matters deserving of consideration, and in some cases it may be desirable to even still further restrict the first growths so as to insure the first crop fruits swelling and being retained, for the casting of the first crop is a great drawback. Of course the varieties differ greatly in this respect, those named in a foregoing paragraph being, perhaps, the most reliable varieties, other conditions being favourable. These are restricted at the roots, surface fibres encouraged and kept active by judicious top-dressings of rich material. Good turfy loam, horse droppings, and old mortar rubbish in equal parts, favour an abundant formation of fibres, and these obtained feeding is an easy matter. To insure uniform moisture a light mulching of decayed manure serves that end and is a source of nourishment, this being added to from time to time so as to keep about an inch thickness. Then liberal supplies of water or liquid manure will be necessary to assist the fruit in swelling.

It is well to continue to pinch out the points of the shoots to form spurs, and prevent overcrowding by timely disbudding, for Fig trees cannot have too much light, the growths being fully exposed to the sun. Extensions and successional shoots will require attention betimes for tying, allowing space for their thickening. The temperature for trees started at the new year or at the beginning of February may now be increased to 60° to 65° at night, 70° to 75° by day with a gleam of sun, and 80° to 85° or 90° under a cloudless sky.

If it is desired to increase the stock cuttings may be inserted, selecting well ripened shoots of about 6 inches length, and taking them off with a heel or portion of last year's wood attached. They root readily in a gentle bottom heat, all eyes being removed from the part inserted in the soil. They are best potted in 3-inch pots, and when rooted should be shifted without much delay into 5-inch pots. From the 5-inch the trees may be transferred to 7-inch pots, but avoid overpotting. Good drainage is necessary, firm potting essential, and turfy loam, with a fifth of thoroughly decayed manure and a sixth of old mortar rubbish, forms a suitable compost. The trees should be trained with a single stem to a height of about a foot, then the point should be pinched to cause side growths to push, about three being retained to form the head, pinching the shoots at from five to six leaves.—GROWER.

Apple Sturmer Pippin.—I think this is a much over-rated Apple. In growth and freedom of cropping it is all that is claimed for it, but in point of flavour in February and March it is sadly deficient. In my own case it does not keep plump, but shrivels, although my store room is a good one, in which fruit of Cox's Orange Pippin will keep quite fresh until the end of February.—E.

Apple Norfolk Beefing.—"W. S.," in his useful notes on page 242, refers to this old English Apple as Norfolk "Beaufin." The name is so given in several catalogues, so the mistake alluded to is excusable. If he turns to Dr. Hogg's "Fruit Manual" he will find this note:—"The name of this Apple is sometimes written Beaufin, as if of French origin; but it is more correctly Beefing, with a good English ring, from the similarity the baked fruit presents to beef." It is a very dark coloured, firm, long-keeping Apple. Dried fruits of it are colloquially known in Norfolk as "Biffius." I have had fruits of it hard, sound, and fresh throughout the month of May.—POMOLOGIST.

Senecio killmandscharica.—This new Senecio (or giving it its more popular garden name, "Cineraria") has recently been introduced from British Central Africa, seeds being sent to Kew in 1893 by Mr. Mahon. It is too early to prophesy as to its ultimate worth as a garden plant, though there is reason to believe that when its requirements become better known it will find a place among greenhouse winter flowering plants. The plants at Kew were allowed to make a few slender branches, which were trained round stakes, and from every node on the upper half of the branches large trusses of flowers are produced. The leaves are somewhat fleshy, varying from 2 to 3 inches across, and are curiously shaped, being almost reniform, with a deep indentation at the top. The flowers are yellow and star-shaped, about the same size and borne in similar sized heads to those of *S. Heritieri*. If, when it becomes better known, its habit can be improved on, it will be a good plant to grow with the ordinary garden Cineraria.—W. D.

Mitraria coccinea.—In the early fifties no greenhouse plant was more interesting to the writer than the Chilean Mitre Flower, with its small opposite or sometimes trifoliate leaves, and solitary flowers of a bright scarlet colour, about $1\frac{1}{2}$ inch long. The habit of the plant is of a trailing sub-shrubby nature, and if trained over a trellis, an upright cylindrical one by preference, a good specimen may be secured, and in which form the writer once grew it for exhibition purposes in a cool greenhouse. In mild districts it has proved hardy out of doors. For growing large specimens from a 12 to 16-inch pot is sufficient, and the plants may be cultivated in the same pots for several years if liquid manure is applied during the season of growth. A compost of sandy peat and turfy loam suits the plant admirably. After flowering the current year's growth should be shortened back to within a few inches of the base. *Mitraria coccinea* (fig. 74, page 273) is one of those much too neglected greenhouse plants which would assuredly receive extended recognition were its merits better known.—W. G.

Impressions of Ferns.—*Apropos* of this subject—your answer to "Journeyman," on page 257—allow me to supplement, for his benefit, the excellent process you describe by another I have successfully employed on various occasions. This is to oil a sheet of foolscap by sprinkling it lightly with salad oil, or any clear oil, distributing the oil evenly over the paper, and allowing the paper to absorb it. When it has gone off the surface smoke the paper by holding it over the flame of a lamp or tallow candle until it is uniformly black. This supplies the medium for printing from. To operate lay the Fern frond face down on the blackened paper, place a sheet of clean paper over it, and rub gently. The frond may then be lifted and placed on a sheet of clean white paper, the blank flyleaf of a book, or whatever it is desired to have the impression upon. By again placing a sheet of paper over the frond without disturbing it another gentle rubbing gives the transference. Any leaves, as well as Fern fronds, particularly those of hard texture, such as the leaves of Roses, give admirable impressions by this method, not only in outline, but the delicate tracery of the veins comes out very distinctly.—K., Dublin.

Apple Lady Henniker.—This Apple, according to the late Dr. Hogg, was raised at Thornham Hall in Suffolk fully fifty years ago. It is a variety not cultivated as much as its merits deserve. Its quality for cooking is excellent, and for dessert it is quite passable; the only fault in this respect is the size. It is a good keeper, lasting well into March. In growth it is vigorous, and in consequence it does not fruit freely in a young state; by allowing it to run rather freely the first few years it gradually gets into a bearing condition. For strong soil it is excellent.—E. M.

A Gigantic Seaweed.—"The largest plant in the world," said an eminent naturalist to a writer in a transatlantic contemporary "is probably a gigantic seaweed, known as the 'Nereocytis,' which frequently grows to a height of more than 300 feet. The stem of the plant is as strong as an ordinary rope, and large quantities of it are dried and used as rope by the inhabitants of the South Sea Islands, where the curious vegetable ropes are found. This seaweed usually grows to a depth of from 200 to 300 feet. As soon as the plant takes root a spear-shaped balloon is formed, which grows with the stem towards the surface of the centre. This balloon frequently has a diameter of 6 feet or more. It has, of course, an upward tendency, and therefore keeps the stem growing until it floats on the top of the water. This enormous weed grows in such quantities that large meadows like islands are formed, which are often so big as to impede navigation. The ropes made from the stems of the plant are used for building purposes, and the balloons when dried make very serviceable vessels."

A New extile Plant.—Some years ago, an explorer in Asia discovered a plant of silken fibre, used by the Turkomans for the manufacture of withes and cord, and by the Canagues for woven goods. This plant, known as *Apocynum venetum*, is a sort of bush with slender cylindrical branches, sometimes 6 feet high. It grows in Europe, Siberia, Asia Minor, the north of India, Manchuria and Japan, but is not cultivated, and, up to the present has been used only in the natural state. The branches die yearly, and in the spring new shoots start horizontally from the roots. It flourishes best where the land is under water during a part of the year, notably in the neighbourhood of rivers that overflow at stated periods. Under favourable conditions the *Apocynum* develops quickly, and in a short time the branches form a thick growth, almost like a miniature wood. The best fibre is obtained, says a colonial exchange, by cutting the branches in midsummer, when the plant has obtained its full growth. The attention of the Russian Government was called to this plant in 1891, and in 1895 they began to use it in the manufacture of bank notes, and since then the plant has been cultivated at Poltava. The results obtained thus far are considered excellent, and the time is doubtless near when the *Apocynum venetum* will take an important place in the textile market.

Large Onions.—A recent note on large Onions and their keeping qualities, as evidenced by the fine sample sent me by Mr. Beckett, inspired another able Onion grower of Hants, Mr. Kneller of Malshanger Park, Basingstoke, to send me a sample, that I might see how his had kept also. Mr. Kneller attributes some of the special keeping properties of these big bulbs this winter to the thorough maturing they got last autumn, and that no doubt has much to do with it. But something is due to the material improvement effected in the character of Ailsa Craig, the variety in question, and still by far the best, by annual selection, the very firmest bulbs and best keepers being specially retained for seed stocks. The Hampshire bulbs were a little larger than the Elstree samples, but otherwise not superior. But all the samples served to show how well the very large ones are keeping this winter. I have planted for securing some seed several of the very best, and others have been, or will be, cooked. Those that have been gently stewed, then served with a little butter and milk, were most delicious and mild in flavour. Onions ordinarily grown have too much of that quality called flavour, which is found in offensive hotness and perfume. It is, therefore, so much to the credit of these big bulbs that those characteristics are lacking, and thus they become, when properly cooked and served, delectable food. Those who would have such this season find they are much too late for seed sowing. But if they have strong plants of Tripolis or Roccos growing in drills outdoors, and having trenched and heavily manured a small area of ground, will in the course of a week or two carefully lift some of these plants, and will dibble them out thinly, they will secure fine bulbs in the summer.—A. D.

Stenogastra concinna.

THIS is a small but attractive stove plant that is by no means so showy as some of its relatives in the Gesnera family. The interest of plant houses, however, does not depend on occupants with large or brilliant flowers, and sometimes a neat little plant like this *Stenogastra* (fig. 73) is quite as much admired as those of more striking character. The leaves are small and oval, the growths short, and the flowers rise in slender stalks only an inch or two above the soil. They have a narrow funnel-like tube, with an expanded limb of five lobes—the two upper very dark purple, the lower a lighter shade of purplish lilac and white, a dark stripe running down the upper part of the tube outside, and inside are numerous dark spots. Flowers are produced freely, and clustered over the plant have a pleasing appearance.

The Royal Horticultural Society.

Drill Hall, March 27th.

THE exhibition on Tuesday was an excellent one, considering the weather that has prevailed of late. Orchids were not generally very numerous, but floral exhibits were plentiful and varied. Apples were not particularly meritorious.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with the Rev. W. Wilks, and Messrs. J. H. Veitch, J. Cheal, G. Kelf, A. Dean, S. Mortimer, J. W. Bates, W. Farr, G. Wythes, W. Balderson, F. Q. Lane, Jas. Smith, G. Reynolds, E. Beckett, J. Willard, G. Bunyard, and H. S. Rivers.

Mr. R. Parker, gardener to the Duke of Richmond and Gordon, Goodwood, staged nine dishes of Apples in good condition, which embraced Lane's Prince Albert, Sturmer Pippin, Norfolk Beefing, Beauty of Hants, and Wellington. Mr. W. Poupart, Marsh Farm, Twickenham, staged five varieties of Rhubarb, to show their respective merits as grown outside at this season. Daw's Champion was far and away superior to the others, and the committee awarded it a first-class certificate, which was richly deserved. Hawke's Champagne came next in point of earliness, but was decidedly behind in both size and colour. Albert followed with less than a third of the growth, while Linnaeus was smaller still under the same conditions. Victoria was only just starting.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and Messrs. C. T. Druery, H. B. May, R. Dean, G. Reuthe, Wm. Howe, J. Hudson, J. Jennings, J. F. McLeod, R. Fife, C. H. Pearson, J. D. Pawle, R. Wilson Ker, Chas. E. Shea, E. H. Jenkins, E. T. Cook, Harry Turner, G. Paul, G. Nicholson, and J. H. Laing.

A splendid collection of hardy flowering plants and shrubs were staged by Messrs. W. Paul & Son, Waltham Cross. The old Double French Cherry, Carnation-flowered Peach, *Staphylea colchica*, Double White Peach, *Forsythia suspensa*, and *Pyrus Malus floribunda* were all deserving of special attention, while their arrangement with a variety of foliage plants left little to be desired (silver-gilt Flora medal). Messrs. R. & G. Cuthbert, Southgate Nurseries, staged a group of *Azalea indica*, Fielder's White, arranged with Palms and Ferns. The plants were all giants, and carried hundreds of flowers, probably thousands; it was certainly a noteworthy exhibit (bronze Banksian medal). Messrs. J. Peed & Sons, Norwood, arranged a group of foliage and flowering plants, such as *Clivias*, *Azalea mollis*, *Ericas*, *Azalea indica*, *Cyclamen*, *Hyacinths*, and *Mignonette*, with Palms, Ferns, *Pandanus Veitchi*, and *Aralias*. The group was spread out to such an extent that most of the pots and other machinery was all too visible.

Messrs. Barr & Sons, Covent Garden, had a large exhibit of *Narcissi*, grown in pots, also in a cut state. The chief forms were *Cynosure*, *Victoria*, *Henry Irving*, *Duke of Bedford*, *Cernuus*, *Emperor*, *Horsefieldi*, *Sir Watkin*, *Mrs. Langtry*, *Catherine Spurrell*, *Cyclamineus*, *Wm. Goldring*, *Emperor*, and *Golden Spur*, amongst many others. A few *Anemone fulgens*, *Scillas*, and *Irises* gave a little brightness to such a large group of yellow and white (silver Flora medal). Messrs. H. Cannell & Sons, Swanley, staged a box of semi-double *Zonal Pelargoniums*, pure white in colour, and a fine improvement on the old *Hermione*, should make a good market variety; it was labelled *All Flower* (Miss G. Ashworth), from which it does not transpire whether Miss G. Ashworth is the actual name or that of the raiser.

Messrs. Isaac House & Son, Westbury-on-Trym, Bristol, staged a table of *Violets* in pots, all well grown and flowered. The following varieties were included—*La France*, *Luxonne*, *Princess of Wales*, *California*, *Admiral Avellan*, *Coolcroonin*, *Mrs. J. J. Astor*, and *R. Augustine*, certainly an interesting exhibit. Messrs. Jas. Veitch and Sons, Ltd., Chelsea, staged some specimen plants of *Viburnum Tinus lucidum* in baskets. The plants were all in splendid health, and well

furnished throughout with attractive white flowers (silver Banksian medal). The same firm also arranged a pretty group of *Clivia miniata* seedlings, which displayed a wide range of colouring, while the plants were carrying large and well developed trusses (silver Banksian medal).

Cyclamens were staged in great variety by the St. George's Nursery Company, Hanwell. The plants were in 5 and 6-inch pots, and all laden with flowers. Some of the plants must have been carrying fifty to sixty fully developed flowers. The same firm also staged a table of *Cyclamen fimbriata*. This is truly a novelty, the foliage being as much fringed as the flowers, but it is decidedly inferior to the old strain as a decorative plant (silver-gilt Banksian medal). Messrs. T. S. Ware, Ltd., Tottenham, arranged a table of hardy plants in flower, including *Irises*, *Primulas* in variety, *Cyclamens*, *Grape Hyacinths*, *Anemones*, *Saxifragas*, *Narcissi*, and others. The exhibit was spread out too much to permit of a good display. A pleasing feature was the group of *Hippeastrums* staged by Mr. A. Cryer, gardener to J. A. Kendrick, Esq., Barron Court, Edgbaston. The flowers were well formed and of good type.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, arranged a collection of *Tulips* and a few *Narcissi*. The *Tulips* were chiefly *Joost Van Vondel*, *Belle Alliance*, *Bacchus*, *Wouwermans*, *Lord Derby*, *Queen of the Netherlands*, *Proserpine*, and *Artus*, while the *Narcissi* comprised the well known sorts, all arranged with little *Ferns* and *Palms*, and a variety of other spring flowering shrubs. A group of *Laburnums*, *Magnolias*, *Stapelias*, *Laurustinus hirta*, and double flowering *Thorns* were arranged effectively by Messrs. Wm. Cutbush & Son, Highgate, but the light from the windows behind somewhat detracted from the display. Mr. J. Russell, Richmond, had a collection of standard and other flowering shrubs, which included *Lilacs* in variety, double *Prunus* and *Guedres Roses*, also *Clematises*, *Azalea mollis*, and *Staphyleas* (silver Flora medal).

Mr. J. May, Twickenham, staged a splendid table of *Cyclamens*, in a variety of colours, the standard reds, whites, and shaded flowers were all included and beautifully developed. The strain is well known, and under Mr. May's care appears to improve, not only in the flowers but in the foliage also (silver Banksian medal). Messrs. F. Cant & Co., Colchester, staged three boxes of cut *Roses*, all being fresh and bright. The following varieties were well represented—*Medea*, *Madame Lambard*, *Perle des Jardins*, *Cleopatra*, *Rubens*, *Bridesmaid*, *The Bride*, and *Niphetos*, also a box of *W. A. Richardson* in superb form (bronze

FIG. 73.—STENOASTRA CONCINNA.

Banksian medal). Messrs. Wallace & Co., Colchester, staged a few choice hardy *Irises*, *Hepaticas*, and *Tulips*, *Hepatica coerulea Warley Blue* being very attractive, as was also *Iris sindjarensis*.

ORCHID COMMITTEE.—Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. H. J. Chapman, J. Coleman, H. T. Pitt, W. H. Young, A. Hislop, E. Hill, J. Jaques, W. H. White, H. A. Tracy, J. W. Potter, H. Little, T. W. Bond, and de B. Crawshaw.

A small group of *Orchids* was arranged by Messrs. F. Sander & Co., St. Albans. Varieties of *Odontoglossum crispum* were conspicuous, with *Cirrhopetalum picturatum*, *Bulbophyllum saurocephalum*, *Cypripedium Svend Bruin*, *Oncidium Wiltoni*, and a hybrid *Cypripedium* from *barbatum* and *bellatulum* (silver Banksian medal). Mr. J. Black, gardener to N. G. Thwaites, Esq., Christchurch Road, Streatham, exhibited *Dendrobiums nobile Cooksonianum*, *n. Ballianum*, *Wiganæ*, *Wardianum*, and others.

A bright and attractive group of *Orchids* came from Mr. T. Thurgood, gardener to H. T. Pitt, Esq., Rosslyn, Stamford Hill. It com-

prised Phaius, Dendrobiums, Lælias, Odontoglossums, Miltonias, Cypripediums, Cymbidium, Angræcums, and others (silver Flora medal). Messrs. H. Low & Co., Bush Hill Park, contributed a small collection of Orchids. The plants proved by the splendid flowers they were carrying the excellence of the methods of culture. There were *Cattleya Schröderæ*, *Dendrobium atro-violaceum*, *D. Findleyanum*, *D. barbatulum*, *D. Brymeriana*, *Odontoglossum Adrianae*, *O. Andersonianum*, and *Oncidium varicosum Rogersi* (silver Banksian medal).

The number of small exhibitors of Orchids was not so large as usual, owing probably to the weather. Mr. J. T. Bennett-Poë showed *Ada aurantiaca*; Mr. J. Davis, *Dendrobium nobile album*; Mr. H. White, *Lælia Cowani* and *Dendrobiums*; Mr. A. J. Keeling, *Lælia Jongheana*; Mr. de Barri Crawshay, *Odontoglossums*; and Sir F. Wigan, Bart., various Orchids.

Certificates and Awards of Merit.

Ada aurantiaca (J. Downes).—This Orchid is far too popular and well known to call for any description (award of merit).

Apple King of Tompkins County (R. Parker).—This Apple is too well known as to need description (award of merit).

Cattleya Trianae Clara Wigan (W. H. Young).—A delicately beautiful variety. The sepals and petals are very soft blush, while the lip is deep rose with a yellow throat (award of merit).

Cyclamen fimbriata (St. George's Nursery Co.).—The papilio-flowered Cyclamen is now followed by a fimbriated-foliaged variety (award of merit).

Dendrobium aggregatum (H. T. Pitt).—A splendidly grown example of a well-known Orchid (award of merit).

Dendrobium Clio superbum (W. H. White).—This is a magnificent variety of the now well-known type (award of merit).

Dendrobium Melpomene (W. H. White).—This is a hybrid from a cross between *D. signatum* and *D. splendidissimum grandiflorum*. The prevailing colour is cream, deepening to canary yellow in the lip. The throat is deep crimson (first-class certificate).

Dendrobium nobile album (J. Davis).—This is a chastely beautiful pure white variety (first-class certificate).

Narcissus Comet (R. O. Backhouse).—A charming form, after the character of *Johnstoni Queen of Spain*, but of deeper yellow (award of merit).

Odontoglossum triumphans Raymond Crawshay (de B. Crawshay).—A superb variety; the yellow is almost wholly obscured by the varnished brown (award of merit).

Pelargonium All Flower (H. Cannell and Sons).—This is a free flowering, semi-double white, that is a decided advance on the old *Hermione* (award of merit).

Rhododendron Dr. Stocker (G. Abbey).—A beautiful white variety, with dull brown splashes on the upper portion (award of merit).

Rhubarb Daw's Champion (W. Poupart).—This variety received an award of merit a short time back, and now receives a first-class certificate.

Violet La France (I. House & Son).—A magnificent variety, with flowers of large size and excellent colour (award of merit).

Pernettya mucronata.

THIS is one of the prettiest of outdoor plants during the winter, when it is covered with its brilliant fruits, which are sometimes produced so freely as to weigh the branches down. It is a native of the extreme south of South America, and is thoroughly hardy in this country, growing freely in almost any situation. It should be planted in a soil that contains a good proportion of peat, and which is otherwise of a rather light nature. Although single plants show well when they have attained their full size, it is better to put six or eight plants together, when they can be seen to the best advantage. When fully developed it forms a plant about 2 or 3 feet high, and as much, or more, in diameter.

The leaves are evergreen, leathery in texture, about half an inch long, smooth and shining on both surfaces, sharply pointed, and rather broadly toothed on both margins. The flowers are small and white, and are freely produced singly in the axils of the leaves, being followed by the globular fleshy fruits, which are the chief beauty of this plant. Normally the fruits are of a bright red, but now many varieties can be obtained with fruits varying in colour from almost pure white to lilac, rose, purple, deep crimson, and almost black. Such names as *fructu lilacina*, *fructu rubra*, and *fructu purpurea* are sufficiently suggestive of the colours of the fruits.

Some of these varieties are extremely pretty, more especially when they are planted to contrast with each other, but others differ little, if any, from the type, and it is difficult to understand why they have received a distinctive name. The fruits are very rarely, if ever, attacked by birds; an important point when dealing with plants which carry their fruits, as the *Pernettya* does, throughout the winter. It is easily propagated by seeds or by division of the old plants, but these divisions require careful nursing for a time.—C.

The Young Gardeners' Domain.

Forcing Peaches and Nectarines.

PEACHES and Nectarines are so closely allied that they are almost invariably classed together, both succeeding in the same house under identical treatment. They are deservedly held in high esteem, and a house of healthy trees laden with fruit is a most pleasing sight, which repays all the care and attention that may have been bestowed.

Before forcing operations are commenced the houses should be well cleaned, washing the glass and woodwork, and lime-washing the walls.

Not much pruning will be required at this season, but the trees should be examined, shortening any shoots that require it, or removing them altogether if too crowded. Dress the trees with some insecticide for the destruction or prevention of the attacks of scale and other insect pests, then tie the shoots to the trellis as evenly and straight as possible. This having been done the border will require attention. If the surface soil is not in good condition remove as much of it as possible without injuring or unduly exposing the roots, replacing it with fresh loam, to which may have been added a good proportion of wood ashes, some lime rubbish, and bone-meal or other artificial manure, making it firm. If

FIG. 74.—MITRARIA COCCINEA. (See page 271.)

the border is at all dry it should receive a thorough watering. It may also be necessary to fumigate the house to keep green fly in check until after the trees have finished flowering, when the syringe will effectually stay the progress of that pest.

In starting the houses it will be necessary to have in view some definite date on which it is desired to have ripe fruit, and from the day of starting to the time when the fruits are required five or six months, according to the variety, should be allowed. A minimum night temperature of 45° ought to be maintained, with a rise of 5° by day from fire heat, with a further advance from sun heat of 10° to 15°, or even more, with full ventilation. Admit a little air at 60°, and increase or decrease the amount as the temperature rises or falls. Damp the borders and paths as often as necessary to supply atmospheric moisture. The trees may also be syringed on bright afternoons, closing early to obtain the benefit of the sun's rays.

Trees that are not subject to bud-dropping are often allowed to expand a large quantity of bloom that is not required. This is an unnecessary effort, and an expenditure of strength on the part of the tree. Before the blossom buds expand it would be well to thin them where they are too crowded, removing those which on account of their position are not available for setting. When the trees are in bloom the night temperature may be raised to 50°, with a corresponding rise by day, allowing a moderate amount of air on fine bright days. Keep the atmosphere a little dryer, but an arid condition is injurious to the floral organs; the house should therefore be damped down occasionally on bright days.

With early forced trees it will be necessary to aid the distribution of pollen by artificial means, that the flowers may be properly fertilised and a good set of fruit secured. For this purpose a camel's-hair brush is the most suitable, passing it gently over the flowers when the pollen is ripe, the operation being performed about midday. Some varieties do not produce pollen so freely as others, but by having in the early house especially one tree of some variety that produces pollen plentifully it may be conveyed from that to other trees, and the perfect pollination of the flowers be thus insured.

When it is seen that the fruits have commenced to swell raise the temperature to 55° by night and to 60° by day. Syringe the trees vigorously on fine days, in the early morning and again at closing time, damping the paths and borders to maintain a humid and genial atmosphere, which is so essential to the progress and well-being of the trees.—S. P.

(To be continued.)

Strawberries in Pots.

STRAWBERRIES for forcing should be layered into 4-inch pots in July. The runners ought to be selected from plants that have flowered the same season, as if from those that have been barren they will not fruit when forced the next spring. In August the plants should be repotted into 6-inch pots, the compost consisting of one-half good fibrous loam, pulled to pieces with the hand, and leaf mould, wood ashes, and dried cow manure in equal parts, the whole passed through a sieve, adding a sprinkling of soot and bonemeal when mixing.

The pots should be clean and well crocked, the plants being potted firmly, and the pots stood on a bed of coal ashes in the open, where they can be frequently syringed. Strawberries at all times should be watered carefully, and never be allowed to become very dry. In October they must be removed to a cold frame or pit, where they will be near the glass; they must be freely ventilated on all favourable occasions throughout the winter.

In most establishments it is usual to commence forcing Strawberries about the 1st of January. The best plants should be selected, the pots washed, and the surface soil removed and be replaced with some good compost. The plants ought to be placed on a mild hotbed in a pit or forcing house for a few weeks to encourage root action, but the temperature must not exceed 50°. When the trusses appear the plants should be removed to an early vinery shelf, and when the flowers are fully expanded they may be fertilised about midday with a rabbit's tail tied to a stick.

When the fruit has set the plants should be syringed twice a day until the fruit shows signs of ripening, when syringing must be discontinued. Strawberries should be fed with liquid manure about twice a week; night soil, carefully diluted, is most valuable if applied when the fruit is swelling. Some of the best Strawberries for forcing are Royal Sovereign, President, Sir Charles Napier, and Vicomtesse Hericart de Thury.—F. W. P.

Poinsettias.

THE Poinsettia ought to have a place in every collection of stove plants. By the present moment the old plants will have had a good season of rest, and may be brought forward and gradually started into growth, once more keeping them as close as possible to the glass to insure sturdy growth, which, to my opinion, is one of the most important points. I would recommend two sets of cuttings to be rooted, one during the latter end of April or beginning of May, and the other at the beginning of July. From the July stock we had the honour of being awarded a certificate of merit for six well grown Poinsettias at the Bristol Mutual Improvement Association on November 30th, the plants standing 18 inches from the tables, and the largest bracts being 17½ inches, and the smallest 15 inches across.

Poinsettias should be rooted singly in thumb pots, plunging them into a frame stood on a hotbed. When they have emitted roots they must be promptly removed to suitable shelves, and they should on no account be allowed to get root-bound, or they will soon lose the foliage, which, when the plants are well grown, extends upwards from the rim of the pots. From thumbs I generally shift them into 4-inch, and from the latter to 6-inch pots, using for the cuttings a very light mixture, but for other pottings equal parts of peat, loam, and leaf mould, with the addition of a little artificial manure and coarse sand. After they have been potted for a day or so they should be syringed, and as soon as they begin to root into the new soil they may be removed to a frame, keeping them well up to the glass, and avoiding cold draughts.

As soon as the weather becomes cold at night the plants should be placed in one of the warmer houses, keeping them well up to the light, and feeding them occasionally with weak liquid manure made from soot and cow excreta, which will assist them very much in pushing their bracts. These will last some time if cut and put in water, or even if the plants are required for indoor decoration; their colour looks very brilliant during the Christmas festivities. After the bracts are over the old plants should be gradually dried off and stored in some warm corner.—W. L., King's Weston.

Hardy Fruit Garden.

Protecting Fruit Blossom.—The cold weather experienced during the past month has been the means of checking the rapid development of the bloom of Apricots, Peaches, and Nectarines. This is an advantage, as the later the trees bloom in spring the better chance there is of securing a good crop. The weather, however, is always uncertain at this time, and there may occur a warm and sunny period during which the flowers will expand rapidly. Following immediately upon this keen east winds and stormy weather may prevail just as the blooms have fully opened. It is at this juncture that protection is needed the most. This must be anticipated, and protecting material arranged in time. The best protection is afforded by glass or wooden copings, from which should be hung lengths of tiffany, scrim canvas, or woollen netting. The material ought to have brass rings attached at the upper ends, and these should run on a slender iron rod, by which means the material may be drawn on one side when not required to cover the trees.

Another efficient means of protection, when a coping is not available, is to lay smooth poles against the walls, firmly fixing them at the base, and arranged 8 or 10 feet apart. Across these stretch the protecting material, which should not be a permanent fixture, unless the material used is fish netting. This can be employed as a permanent protection—that is, from the time the blossoms expand until the foliage has well developed, when artificial protection is unnecessary. To be thoroughly effective fish netting should be used double or treble thickness. In the absence of poles on which to hang the netting it may be depended from the stone coping of the wall, but ought not to touch the trees, as in the event of wind damage might result to the blooms or young fruit. The temporary expedients which are sometimes employed, such as evergreen sprays placed among the branches, are not to be depended upon to afford efficient protection.

Feeding Old Fruit Trees.—Sewage water, the contents of cesspools, is admirable nutriment for pouring on the soil over the roots of large old fruit trees. By giving a good application now, it will sink into the moist soil and convey rich and valuable plant food ready for the roots to imbibe when they put forth new fibres incited into activity by the warmth of spring. Old trees on grass, which cannot so readily be supplied with manure, will be largely benefited. The best means of conveying it down to the roots is to make holes at intervals with a crowbar, and pour the liquid into them, filling up several times. The strength of the liquid is immaterial. It will not damage the roots, especially as the soil is moist.

Feeding Bush Fruit.—Gooseberries and Currants that are in free bearing condition appropriate considerable quantities of food from the soil during the developing of the fruit, hence it is desirable that suitable nutriment should be within reach of the roots when their demands are greatest. It is advisable, therefore, if liquid manure is available, as sewage water or drainings from stables, cow sheds or manure yards, to apply it now, well moistening and enriching the soil as far as the roots extend.

Fertilising Strawberries.—Fresh pungent soot scattered thinly round the crowns and more liberally on the soil over the roots at the rate of a peck per rod is exceedingly stimulating food for Strawberries. A dressing of guano 1 oz. to the square yard forms rich and stimulating diet. Liquid manure may be given occasionally, and a good dressing of manure laid down between the rows.

Outdoor Figs.—Trees on walls may now be regulated and trained after pruning, which should consist of cutting out the old exhausted shoots or weakly branches, retaining the young current year's growths in sufficient quantity to occupy the available space, leaving them at full length.

Planting Strawberries.—Young plants have time to become fairly well established before the advent of hot, dry weather. They should, however, be inserted on good rich ground. If the roots are devoid of adhering soil spread them out carefully in planting, covering with fine material. If plants can be lifted from nursery beds with good balls of roots they will suffer little or no check in removal. The ground should be made firm previous to planting, and if burnt refuse is mixed with old potting soil the compost forms a good bed into which the first new roots can readily push. Some such material is necessary in stiff ground in order to give them a fair chance. Water well should the weather be dry.

Thinning Fruit Blossom.—Where practicable on small trees or cordons of choice varieties it is an excellent plan to remove superfluous blossoms. All fruit trees produce blossoms in positions where it is quite inconvenient for fruit to set, swell and develop. These superfluous blossoms which lay behind the branches and shoots ought first to be removed. Follow with a general thinning out of the remainder. This removal will considerably benefit Peaches and Nectarines, Apples and

Pears, which invariably produce more bloom than desirable, rendering the chance of securing a good set rather improbable.

Forking and Hoeing Fruit Borders.—The practice of digging between fruit trees and bushes is not to be recommended, as it is liable to mutilate the fibrous roots if they are present near the surface. Pointing the soil over among bushes and between large trees may be adopted, but it must not be carried out deeply. Ground that has been previously treated will now require nothing further than breaking the surface with a hoe in order to cut down seedling weeds, and make a pulverised surface.

Fruit Forcing.

Cucumbers.—On bright days, especially after a period of dull weather, shade from powerful sun will be necessary to prevent flagging, but it should only be used for a few hours at the hottest part of the day. Plants in full bearing will need assistance with top-dressings of fertilisers or applications of liquid manure, adding fresh warmed soil to the beds as the roots protrude. Thin out the exhausted growths of plants that have been in bearing some time, and encourage new bearing shoots. If worms are troublesome expel them with lime or soot water, a peck to 30 gallons of water, stirring well, letting it stand forty-eight hours, then watering with the clear liquid. Subdue canker at the collar and in the old growths by rubbing quicklime into the affected parts. Damp the floor in the morning between seven and eight o'clock, and again in the afternoon about three o'clock, syringing the foliage gently on warm afternoons, and keep liquid manure in the evaporation troughs. Attend to stopping, thinning and training, at least once a week. Maintain a night and dull-day temperature of 70° to 75°, 80° to 90° by day with sun, and close sufficiently early to rise between the latter degree and 100°, with an abundance of atmospheric moisture. Ventilate moderately and early, avoiding sudden changes of temperature, also currents of cold air, which cripple the foliage and cause the young fruit to become deformed and to swell irregularly.

Pits and Frames.—Cucumbers in these require the growths trained rather thinly, pegging them down as required, stopping one joint beyond the show for fruit, or the leading growths about 1 foot from the sides of the frame. Maintain the requisite heat by renewing the linings. Add fresh warmed soil to the hillocks as the roots extend. Be moderate in the application of water, as the nights are as yet cold, and employ thick night coverings. Admit a little air early so as to have the foliage dry before the sun acts powerfully upon it. The heat through the day may range from 75° to 90° with sun. Close early in the afternoon, no harm accruing if the temperature rise to 90°, or even 100°, provided there is no rank vapour. If there is danger from it admit a little air constantly, a small opening being sufficient to allow it to escape, as it is very light.

Melons.—The earliest plants will have fruit set or setting on the first laterals. A rather drier atmosphere, and no more water than to prevent flagging, with an increase of temperature of 5°, and a circulation of warm air, are desirable during the setting period. The flowers should be fertilised every day when fully expanded, pinching out the points of the shoots one or two joints beyond the fruit. When the fruits are set, and the size of Walnuts, give the bed a thorough watering, and in a day or two add soil to the sides of the ridges or hillocks, pressing it firmly, and again supplying water or liquid manure. The soil, water, or liquid should be warmed to the temperature of the bed. Stop the subsequent growths to one or two joints, and prevent overcrowding by rubbing off shoots for which there is not room for the foliage to have full exposure to light. Do not overcrop the plants, but leave the fruit proportionate to the vigour, say two on weakly, three or four on vigorous, and very strong plants may carry six fruits.

A night temperature of 65° to 70°, 75° by day, ventilating from that point, increasing with sun to 85° or 90°, closing early to secure the latter degree, or even rising to 95° or 100°; bottom heat 80° to 85°. Damp the house in the morning, syringe moderately by or before three o'clock on bright warm afternoons, damping the paths and walls in the evening. Keep the evaporation troughs filled with liquid manure. Plants in narrow beds will require plenty of liquid nourishment, always in advance of the mean temperature of the house, and top-dressings of rich material.

Successional Plants.—Train the growths regularly, remove every alternate lateral, rubbing them off directly they are perceived, the remainder being trained to the right and left of the stem. Pinch out the points of the primary shoots after they have extended two-thirds of the required distance. Increase the supply of moisture both at the roots and in the atmosphere as the days lengthen. Pot seedlings, shift into large pots, and plant out as required. Sow more seeds to afford plants in proportion to the wants of individual establishments. In pits and frames a bottom heat of 80° should be secured to plants that are growing freely, renewing the linings as required. In newly made beds the bottom heat should be about 80°.

Peaches and Nectarines.—*Earliest Forced Houses.*—When the very early varieties, such as Alexander, Waterloo, Early Beatrice, and Early Louise Peaches; Advance, Cardinal, and Early Rivers Nectarines give indications of ripening syringing must cease, and the leaves that shade the fruit be drawn aside, raising the fruit, if necessary, on laths placed across the wires of the trellis, so that its apex will be directly to the

light. Such varieties as Hale's Early, Stirling Castle, Royal George, and Dymond Peaches; Lord Napier, Stanwick Elruge, and Goldoni or Humboldt Nectarines, on the other hand, must not be hurried until the stoning is completed, continuing the temperature at 60° to 65° at night and on dull days, 70° to 75° by day with sun heat, and free ventilation, avoiding sudden fluctuations and depressions.

Regulate the growths, not having those for future bearing too close, but give them ample room alike to benefit the fruit and the wood. Shoots disposed to grow more than 14 inches may have the points pinched off, but extensions should be trained in their full length. When the stoning is completed regulate the crop for the final swelling. Vigorous trees may be allowed to carry more than one fruit to each square foot of trellis, while weakly trees should not be permitted to bear so many. Supply liquid manure to weakly trees, the inside border in any case being kept properly watered, mulching the surface with a little well-decayed manure, in order to secure uniform moisture and favour the surface roots.

Trees Started at the New Year.—Thin the fruit to a few more than is required for the crop. Avoid sudden checks by judicious ventilation, cold air in the daytime and a high temperature at night proving fatal to the fruit stoning. A night temperature of 60° to 65°, 5° less on cold nights, and 65° by day in dull weather, with 70° to 75° from sun heat, is quite sufficient, ventilating from 65°.

THE BEE-KEEPER.

Work in the Apiary.

As a guide to other bee-keepers it may be of interest to state what is now being done in our apiary. It is a recognised fact that to be successful in any business preparations must be made in advance of requirements. We are therefore doing all that is possible towards the desired end. At present we are overhauling spare hives. Those that require it are repaired and made thoroughly sound, as an unsound hive often means the loss of a strong colony of bees. This must be guarded against. After the hives are repaired they should receive at least two coats of paint made from the best white lead. This must be well worked into all the crevices, and should there be any small cracks in the wood they ought to be filled with putty after the first coat of paint. If this work is well done the hive will withstand the various changes in the weather for at least two years.

The inside of hives that have been in use for a long time should also receive attention. We do not recommend the interior to be painted, as the moisture will condense on the sides if this is done. Our usual plan is to use a new hive for a few years without any dressing whatever inside. But at this season when from various causes we have several old hives on hand after being treated as above, the propolis is scraped off the sides and the whole of the interior receives a dressing of Stockholm tar and carbolic acid. This mixture must be put on hot, and the plan we adopt is to place the tar in an old saucepan over a clear fire, and is made of the consistency of paint by adding carbolic. An ordinary paint brush is used for applying the mixture, which should be well worked into all the crevices. This will have the effect of destroying any germs there may be, and will also preserve the wood and sweeten the hive. One application will be sufficient. If the fire is not clear and bright there is a danger of the mixture bursting into flame. If this takes place the saucepan should be immediately placed on the floor and if the back of a shovel is put on the top the flames will be overpowered at once.

The hives should be placed in the open air for a few days, and the smell will soon pass off; and the hives will be ready for use when required. The advantage of doing them at this season is—they will be ready for the early swarms, or for whatever purpose they may be required. Some hives in our apiary that were recently treated in this manner have been in constant use for nearly twenty years.

Preparing for Another Season.

Preparations should now be made for the coming season. Whether it will prove good or bad from a bee-keeper's point of view remains to be seen, but we must prepare. A general stocktaking should take place, so that when the necessary things are required they will be ready to hand. If an increase of stocks is contemplated the requisite hives should be obtained, either by making them on the lines of the approved hive at present in use in the apiary, or by ordering them from some well-known maker. These should be obtained unpainted. It will then be possible to see if the wood is of good quality. The painting may afterwards be done at home. There is often a difficulty in obtaining goods during the height of the season, when manufacturers are working at high pressure. Sections may be obtained in their original cases; these are usually imported in boxes holding 500,

and are much cheaper when obtained in this manner. If kept free from dust they will remain in good condition for an indefinite period.

It is a great saving of labour to the bees to use comb foundation; sufficient should therefore be obtained to last throughout the season. It will also keep in good condition for several years. All that is required if it becomes dry and brittle is to place it in the sun for a few minutes. Holding it before the fire will have the same effect. It is not necessary to use the thick foundation often recommended for the brood combs, and which only averages six to eight sheets standard size to the pound. It thus becomes expensive when numerous colonies have to be supplied. We always use the thin for all purposes, which averages sixteen sheets to the pound.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Matricaria eximia Golden Ball (*Somerset*).—It will be best to treat this as a half-hardy annual, sowing as soon as possible in heat; prick off into boxes or pans to strengthen, and plant out at the end of May. It will flower well in autumn. Seeds may also be sown outdoors at the end of April. With good treatment these plants will also flower the same summer or autumn.

Schizophragma hydrangeoides (*Climbing Hydrangea*) (*Idem*).—This evergreen greenhouse shrub, of climbing habit, which was introduced from Japan in 1879, requires to be grown in good well drained soil on a sunny wall. As it is hardy it may also be grown outdoors on a sunny sheltered south wall. Plant in April. It is self-clinging, and will reach a height of 12 to 18 feet. The flowers, which are produced in autumn, are pink.

Pressing Wild Flowers (*Tyro*).—The principal point needing attention is in the drying, as this process must be performed gradually, or the characters of the plants will not be preserved. Thick porous paper is used, and the specimens must be carefully spread out in as natural a manner as possible, preserving the form of flowers and leaves, and in the case of small plants the natural habit. The sheets of paper and specimens should then be placed in small piles, with a stout board below, and one on the top; upon the latter weights can be placed to provide the necessary pressure. The specimens must be frequently examined in the early stages, and if there is much moisture on the paper fresh sheets should be supplied and the others dried before being used again. Do not be in too great a hurry to complete the process, some plants require a long time, and if any attempt is made to "mount" them before drying is completed it will cause much after trouble. When, however, it is seen that the substance of the plants is thoroughly dried the specimens can be secured to stout sheets of white paper, by means of thin glue or strong gum applied to the principal parts of the leaves or stem, or what is preferable, by means of narrow strips of paper placed across the stem, leaf and flower stalks, and fixed to the paper by their ends with the glue. Always employ large sheets of paper, so that ample room can be allowed to the specimen, and do not fix them all in the centre of paper, but let some be near the sides, as it will be more

convenient for arrangement in the herbarium, as it equalises the pressure. At the base of the sheet the botanical and common name of the plant should be given, its natural order, and the place where it was found, with the date.

Rose Seven Sisters (*H. S. J.*).—Yes, there is a Rose bearing the common name of Seven Sisters. It is a variety of *Rosa multiflora*, a very beautiful, free-growing and flowering class of Rose, introduced into this country from China over three-quarters of a century ago, under the name of *Rosa multiflora Grevillia*. The name of Seven Sisters was no doubt applied to this Rose in consequence of the great diversity of colours displayed in the blooms, which, as you correctly state, grow in clusters of seven or more. As the blooms expand, one will assume a crimson, one a purple, and another a rose colour, and when matured and beginning to fade, the three colours may be seen blended beautifully together in a single bloom. Unfortunately these Roses are not sufficiently hardy for general planting out of doors on account of their disposition to start into growth early in spring, and thus getting their shoots killed by the frost. On a well-sheltered south wall the Seven Sisters would do well if the precaution is taken to cover it up with mats during winter and early spring. Planted out in a cool greenhouse or conservatory and allowed to ramble along the roof it would succeed better still.

Fairy Rings on Lawns (*G. S. C.*).—The so-called fairy rings are caused by fungi, the most common being the Fairy-ring Mushroom or Champignon, *Marasmius oreades* (fig. 75). It grows on lawns, grassy hills, wind swept pastures, and amongst the short grass of roadsides. Many other fungi are capable of making fairy rings, that is, they grow

FIG. 75.—FAIRY RINGS.

in circles, that of the species named being usually narrow and regular in outline. The ring probably starts from a single fungus (A), which has grown from wind-carried spores, and the growth of the spawn from it (B) in the ground renders the spot unfit to produce another fungus of the same class. When the ring of fungi dies it acts as a rich nitrogenous manure for the grass. This circle contrasts strongly with the adjoining grass infested at the root by the spawn of the fungus, which is very sickly and yellow. The rings are not always regular, being broken here and there, according as circumstances favour the development of the spawn. The large fungi giving rise to fairy rings do not often occur on lawns. The St. George's Mushroom, *Tricholoma gambosum*, which appears in spring, produces very bold fairy rings, the spawn eating up the roots of the grass, and the fungus itself manuring the circle in a very decisive manner. The common Mushroom does not give rise to fairy rings, but the Horse Mushroom, *Agaricus arvensis* often produces rings, and other instances of ring formation by fungi are well known. These rings do not occur in rich pastures to any marked extent, hence manuring may be said to be the best means of getting rid of them, the soil being made equally rich all over as that of the fairy ring. This is sound in practice, for on a lawn the fairy rings were a great eyesore, and a good dressing of thoroughly decayed manure in February, the rough being raked off at the end of March and the lawn rolled, obliterated them, the ground being top-dressed with a mixture of soot, air-slaked lime, and wood ashes in equal parts by measure, a peck of the mixture being used per square rod, after clearing off the rough parts of the manure. In another case excellent results followed the use of lawn manure at the rate of 3 to 4 ozs. per square yard. As to taking out the soil where the fairy rings are it is probable they would appear again, for it is hardly likely the whole of the mycelium would be removed. Besides, there will be plenty of spores about, and it is only a question of their being wind-carried on the lawn to start fresh rings. We therefore advise the manuring of the lawn, and as a special means of destroying the mycelium of the fungus make holes with an iron rod or crowbar about 6 inches apart and deep, extending 6 inches outside the ring as well as in it, and fill these with a solution of Jeyes' fluid, a wineglassful or 2 fluid ozs. to about 4 gallons of water, applying also to the surface by means of a rose. When soaked in the holes may be filled with good soil made firm. Then manure the lawn all over or supply a lawn manure according to the instructions supplied.

Spots on Tomato Leaves (Cross).—The spots on the leaves are caused by the spot fungus, *Cladosporium fulvum*, syn. *Lycopersici*, but the spores so far have not developed, which is not uncommon early in the season and in a rather low temperature. By maintaining a rather high temperature from sun heat, but with a circulation of air, and keeping a gentle warmth in the hot-water pipes, so as to keep the air in motion, and even admitting a little ventilation to promote it, there is not much to fear from the spread of fungus. We should, however, maintain a night temperature of 55°, and 60° to 65° in the daytime from fire heat, ventilating a little, and allowing a good advance from sun heat, with proportionately increased ventilation. As a further safeguard a little sulphur may be used on the hot-water pipes, as the fumes given off, even scarcely perceptible ones, are inimical to fungoid germs.

Tomato Leaves Turning Purple (Idem).—The purple hue is peculiar to some varieties, and a characteristic of good health rather than otherwise. It has been attributed in its bluish form to an excess of iron in the soil, but this, in your case, can hardly have resulted from the ground last year having a sprinkling of sulphate of iron. The tendency of sulphate of iron is to promote the chlorophyll or green colouring matter of leaves and young growths, but it also aids the peculiar characteristic purplish hue of some plants. Some growers consider the purple due to potash. Possibly a deficiency of manure or available nitrogen in the soil may tend to increase the purple colour. The foliage, however, is not deficient in substance, and the growth appears free so that we do not advise the application of manure at present, unless it be a very light sprinkling of dissolved bones. The water employed ought to be of the mean temperature of the house, as cold water or that of minimum heat tends to check the growth.

Clanthus puniceus (M. B.).—This plant requires an ordinary greenhouse temperature such as you appear to have provided, and its bright red flowers are usually produced freely. Possibly the plant is in too rich a soil. A rather sandy loam is the best, and it is only when the root space is restricted that manurial assistance is needed. When grown in pots, for instance, and strong, well-rooted flowers have been obtained, a little well-decomposed manure incorporated in the soil is beneficial, or occasional supplies of weak liquid manure will be equally helpful. An important point is to syringe the plant freely while it is growing, as it is liable to be infested by red spider if that be neglected. It is also desirable to harden and mature the growths by moderate exposure to sun and liberal ventilation. During winter much less water is needed.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (T. S.).—1, *Odontoglossum gloriosum*; 2, *O. Edwardi*; 3, *O. grande*. (J. L.).—1, *Libonia floribunda*; 2, *Cytisus racemosus*; 3, *Iris fimbriata*; 4, *Primula verticillata*; 5, *Anthericum variegatum*. (Young Orchid Grower).—1, *Cymbidium eburneum*; 2, a good form of *Cattleya Trianae*; 3, *Cypripedium barbatum*; 4, *Cymbidium Lowianum*; 5, *Angraecum sesquipedale*.

Names of Fruits (H. H.).—1, Winter Hawthornden; 2, Grange's Winter Pearmain; 3, Bess Pool.

Pigs.

A SHORT word, but full of meaning. We are called a nation of beef eaters, but really we are also quite, if not more, indebted to "Mr. Pig" for our main meat supply. Of course, useful as he is, he is not of such absolute importance to the upper and middle classes as he is to the working man, but our breakfast tables would present a poor appearance without some adjuncts from pigdom. He is far more the poor man's animal than the cow. He can be housed at so little expense, can be bought at less, will eat what the cow despises, and every ounce of him can be consumed with relish by the man and his family. In a country like England, where cold weather is more in evidence than hot, fatty substances are required to keep the system warm, and next to butter there is no fat so pure and good as that of pig. He is easily cured and easily cooked, and is so "relishable." Of course, he is "mortal," like all live stock, but at the same time he might be called, in insurance parlance, a "healthy life." He is essentially an animal for the country cottage, where his sty need not be quite at the very door. Town pigs are odious and expensive. All food has to be purchased, and then the areas are so limited. Pig and garden should go together. All he takes from the garden he amply repays by the value of his excellent manure. His diet is much

improved by the addition of any rough coarse grass that the children may obtain from hedge bottoms or roadsides.

There are several erroneous ideas respecting a pig's habit and bill of fare. He has the character of thriving in dirt. Well, the dirt is not his fault; it is to his credit that he does so well among it, but clean him and make him comfortable and he repays you at once. Too little attention is often paid him. He has to put up with bad accommodation, and with little or no bedding. His abode should at least be weatherproof, and good bedding is essential to his comfort. He has no thick coat of wool or hair to keep off sun or cold, and he needs protection from the hot glare as he does from the biting frost.

We require a variety in our food. Let it be ever so good the same dish soon palls; the system requires a change; the blood must be purified, and it is one of the greatest of mistakes to keep the pig on hard corn or concentrated meal all the year round. Potatoes are a great stand-by, and they make a most excellent food steamed and mixed with meal. We should say there is no bacon in the world that beats that produced from barleymeal and Potatoes. But steaming should not be confined to Potatoes. If there be plenty of Turnips and Mangolds to spare, they make excellent cooked food. By the way, if there be any Mangolds over in summer—that is, spared from the ewes and lambs—it will well pay to give them to the pigs. Pigs must have change of food, and it is the greatest mistake to feed them so much on hard dry corn. Pigs have a nasty habit of rooting about too much, therefore it is almost necessary that their green food be brought to them; and as soon as there is any green food astir on the farm the pig should have his share. Rye will come in first; Clover and Tarcs if they can be spared, and as soon as a harvest field is cleared let the pigs have a run, with a day lad as tenter.

It is a great mistake to keep young pigs too long about. Small weights of good quality are always in demand, and to be of good quality they must never be allowed to go back. If the sow be well fed they leave her in prime condition, and it then depends on the farmer whether or no they keep that condition. "Small profits and quick returns" should be the motto. Of course some have to be kept to supply the household with bacon, and a farm household is rather a wide term, as in many places the master, by agreement, supplies his labourers with so many stones of bacon per annum; also the foreman requires 25 stone or thereabouts per annum for each waggoner he boards. It would not pay, of course, to kill for them prime young porkers; strong big pigs are wanted, say from 25 to 30 stone weight. But the money to be easiest made will come from those porkers which are sold fat and young.

When the little pigs are about three weeks old they will begin to eat, and should be encouraged so to do, but the food must be such as they can manage easily without detriment to their teeth. Grains of soaked maize ought to be scattered about, and a few Oats. The piglings should be able to get at their food without interference from the sow, and ought to be provided with plenty of slop in the way of skimmed milk, or failing that thin barleymeal water. Plenty of sunshine, and a run on grass if possible, and plenty of muscle and bone-forming food. Oats, barleymeal, and Peas come first in order of value. Maizemeal tends too much towards fat, and fat must not be encouraged at the expense of growth. Bran should not be given till the pigs are at least three months old. We put much stress on the value of old milk. In no other way can milk be made to pay so well as in the insides of little pigs. In Denmark this has been proved by a series of elaborate experiments. It stands to reason that in feeding sucking pigs well two ends are gained. The pigs are always on the upward move, developing quickly, and getting out of the way, and there is not such a strain on the system of the sow—the better her condition the sooner she will be fit for other duties. It may be breeding again, or it may be the salting tub, at any rate she has lost no time. At one time or another we have heard a good deal of pig ailments, and our only surprise is that we have not heard more. The matter in a great measure is in our own hands; the remedy lies with ourselves.

We go back to the first point, sanitation. Unhealthy dwellings

make unhealthy inmates; impure water, bad food always work out to the same result, and we are beginning now to see that it is little use to lock the door when the horse is stolen. Of course we know how difficult it is to keep free from horrible epidemics like swine fever or foot and mouth disease. Swine fever being difficult of identification in the early stages, may get a hold on a herd before the owner is really aware of the deadly enemy. We have a great objection to the purchase of pigs from unknown sources in the open market; the risks are so tremendous.

Happily of late years we have been free from "foot and mouth," although there has just been a local outbreak in Norfolk. It is a catching complaint, and is easily communicated from "bos" to "boar," so that in case of any outbreak among the horned cattle the pigs should be at once isolated. If only farmers would use a little more lime, either on the floors or as a wall wash, and a few simple disinfectants, they might save themselves many a funeral, and many a long farrier's bill.

Work on the Home Farm.

Except for a heavy snowstorm on one afternoon we have had a fine week. The snow soon melted and did no harm; in fact on land which was recently worked and drying quickly it did good.

Drilling is proceeding rapidly everywhere, and Barley is going in fairly, but we have seen no March dust this season, and the land is hardly so warm as it should be; in fact we want more sunshine. These cloudy skies and north-east winds are as bad for the land as they are for the live stock. If the old rule about the equinox holds good, we are to have a cold, dry spring, for the wind was in the north-east at that period. At present everything points to a late harvest.

Lambing will soon be over. We have heard of only one instance of ill fortune this season, and that was attributed to the ewes having had too many Turnips. There must have been great want of discretion. There has generally been an exceedingly small loss of ewes, lambs have been fairly plentiful, and though not big and strong they are healthy and doing well.

Keeping is very scarce, for there is little grass, and haystacks are dwindling rapidly. A town milkman tells us that he has never had so much milk, and his cows have never had a root. He has been using cut straw and hay with a plentiful supply of fresh grains and bran mash. He usually used 50 or 60 tons of Swedes; this winter he has used none, and has sold seven cows fat at £20 each. This shows what necessity can do. The land for the Thousand-headed Kale should be nearly ready, as the seed ought to be sown in mid-April. Manure and till as for Swedes, and drill 18 inches apart; 3 lbs. per acre, or a little less if it can be got on regularly, will do. The seed is scarce and dear, new seed being 2s. per lb., and new is always the cheaper in the end.

Draught mares are beginning to foal. Early foals may be desirable for people who exhibit, but April is quite early enough for a farmer to have the troubles of foaling and foals. Considering the great risk which mares incur in foaling it is wise policy to have both mare and foal insured. Even then there is great anxiety until mother and foal are safely out at grass. As foaling time draws near it is most necessary that the mare should not be left. Delivery often occurs very rapidly, and in five minutes the foal may be born and smothered for lack of a helping hand to free the nostrils. For this reason a man awake and on the alert should be within hearing distance of every movement. Assistance should also be within easy reach, so that it may not be necessary to leave for more than a minute or two.

THE HORSE TRADE IN AMERICA.—The number of horses sold at Chicago stock-yards last year was 111,611 as against 118,754 in 1898, which was the highest year's record since the commencement of the tabulated returns in 1865, when the total number received in the stock-yards was but 1563, a striking contrast to the numbers given for the past and previous years. A report from the large centre under the date of January 31st says that owing to the South African War having requisitioned so many ships for transport purposes that the Chicago dealers have been unable to secure sufficient accommodation for the horses purchased, and it is anticipated that until the release of the transports this difficulty will continue to exist, and must to some considerable extent affect the trade, whilst the high rates of freights will also become a factor in connection with this section of the trade. Looking at the prospects of the horse breeding industry in a general way throughout both the States and Canada, there are strong indications of a revival of the demand for imported stallions, more particularly of the heavy draught type, for it is becoming more and more evident that for this class of horses the demand is better and the prices higher than those realised for 'bus, cab, or light van horses. The Percheron is very popular in some districts, and there is a very good demand for this class of horse. At a recent sale of a stud of this breed thirty-six head averaged just under £80 all round.—("Farmer and Stock-breeder.")

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH.

NOVELTIES & SPECIALITIES FOR 1900.

Amaryllis, Barr's Choice New Hybrids, saved from a magnificent collection. Per packet, 2/6.
Aster sinensis, a lovely single Aster, with large handsome flowers of a delicate mauve with yellow disc, bushy, branching habit, ht. 15 in. Per packet, 1/- and 1/6.
Candytuft, Barr's Giant White, very large spikes of snowy white flowers. Per packet, 6d. and 1/-.
Celosia plumosa, Barr's Choice Mixture, handsome feathery plumes of bright colours. Per pkt., 6d. and 1/-.
Lantana, Barr's New Dwarf, a mixture of brilliant colours, charming as a pot plant. Per packet, 1/6.
Lupinus arboreus Snow Queen, a pure white Tree Lupin, fine novelty. Per packet, 1/- and 1/6.
Mignonette, Barr's Covent Garden Favourite the finest Mignonette for pots or borders, the handsome flower heads are deliciously fragrant. Per pkt., 6d. and 1/-.
Nicotiana sylvestris, a fine white-flowered Tobacco with handsome foliage. Per packet, 6d. and 1/-.
Petunia, Barr's Superb Giant, the largest and handsomest of all the Petunias, immense flowers of rich and varied colours. Per packet, 2/6 and 3/6.
Phacelia campanularia, one of the most lovely blue flowers in cultivation, height 8 in. Per pkt., 6d. and 1/-.
Poppy, Empress of China, snow-white single flowers, with a fringed margin of crimson-scarlet. Per pkt., 6d.
Poppy, Shirley, Barr's extra selected strain of this beautiful annual Poppy. Per packet, 1/-.
Rose, Miniature Fairy, dainty little semi-double flowers of various shades, blooms first season. Per pkt., 6d. & 1/-.
BARR'S SEED GUIDE contains a Select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM
 AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The **BIGGEST SUCCESS** of all is **ECKFORD'S GIANT SWEET PEAS**. The **PURITY** and **STAMINA** of these Home Grown Stocks are so conserved by **SPECIAL METHODS** of **CULTURE** that the seeds are **PHENOMENAL** for **UNRIVALLED STRENGTH** and **VITALITY**, and with proper cultivation, give the **HIGHEST POSSIBLE MAXIMA** of results! Prizes offered in 1900 alone exceed **£40!** Collections from 1/6 upwards.
 (See particulars in Catalogue.)

See beautiful plate of **SWEET PEA NOVELTIES** for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively **UNRIVALLED** by any on the Market for **FLAVOUR** and **CROPPING CAPACITY!** **ENORMOUS YIELDS** under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from **ALL QUARTERS** prove that **ECKFORD'S SEED**, for **PURITY**, **VIGOUR**, and **YIELD**, are the **CHEAPEST** and **BEST** ever offered to the Public! Collection for 12 months supply, **12/6**, **21/-**, **42/-**, **63/-**, **105/-**, all carriage paid. Other Collections, **2/9**, **5/-**, **7/6**, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelty and Grand Collection of named varieties
PANSY. World-famed strain of **FANCY, SHOW, PEACOCK**, and **FLAKED VARIETIES!**
VERBENA. RENOWNED RACE of **EXCEPTIONAL MERIT!**

Don't buy till you have seen it! **ILLUSTRATED Catalogue & Cultural Notes POST FREE!** If you love Gardening send for one!

HENRY ECKFORD,
 SEED CROWER, WEM, SHROPSHIRE.

BEGONIAS, TUBERS & SEED.

THE BEST COLLECTION. Catalogues Free.

Seed, Double and Single, choice, each 1/6 and 2/6 per pkt. Extra Superb Hybrid, from newest and best flowers only, each 5/-.

B. R. DAVIS & SONS, YEovil NURSERIES, YEovil, SOM.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirits to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"**WEST'S EXTRACT OF NICOTINE**," is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"**SUNPROOF**" **SHADING** in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

"**WEST'S INSECTICIDE**" can be proved to be the best and cheapest by sending for a free sample box.

For particulars of West's Patent "Ivorine" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Crocks, West's Fertiliser, West's Weed Killer, West's Lawn Sand, &c., &c., see **ILLUSTRATED CATALOGUE OF WEST'S PATENT GARDEN SPECIALITIES**, post free.

Samples free; postage for samples and goods extra. All goods made on the premises by C. E. West.

Gratis, "**Orchid Culture**," 3rd Edition, postage 2d., Gives full particulars of the cultivation of Orchids.

The Garden Campaign.

MAy not life be regarded as a series of combats, and the various incidents in it as items in a campaign? These may be so small as to be practically unnoticeable, except by those whom they intimately concern; or they may be of such a character, in magnitude and consequences, as to rivet the attention of the world.

A campaign of the latter nature does not need to be particularised. Though far away it is very near, and not long absent from the thoughts of most of us in our waking hours, while it must almost of necessity haunt not a few in their mid-night dreams. Though all the world admires the bravery of brave and fearless men, and we in this island home of ours glory in the prowess and success of our heroic fellow subjects, yet the world-commanding duty in which they are so devotedly engaged is one of war and waste—a process of purification we would fain hope, and, like prairie and forest fires, the precursor of smiling fields and a fruitful land.

Our share, as horticulturists, in life's duties and responsibilities is of a wholly different nature. We may be said to be engaged, and it is hoped worthily and effectually engaged, in the great commissariat department of the nation. As wide as the poles asunder are our objects and methods from those above indicated. But still there is, what may be termed, mild similarity. The carrying out of a military campaign involves destruction, devastation, death, mourning, and great tribulation. These have always been incidents, paradoxical as it may appear, in human progress.

As just suggested, analogy may be found in the vegetable kingdom of the wonderful world in which we live. We prune the subjects in our particular domain to make them fruitful, not always wisely, it may be conceded, but that is the object. We cut out the cankered arms and limbs without hesitation when the necessity is assumed to arise, but we dress the wounds as if in mercy and for a healing purpose. We do not even scruple to behead

old friends, though they have been serviceable in their day and generation, but we do so to invigorate, or renew by the surgical art of grafting.

We uproot and utterly destroy ancient colonies, and consume them with fire, in order that new life and vigour may arise from their ashes, and wholesome food-producing successors flourish. We combat the enemies of these ruthlessly, and drench, poison, smoke, or stifle them without compunction. We are, in fact, ever engaged in combat; yet ours is not a war of waste—the sacrifice of human life and all that may conduce to its happiness—but a campaign of peace and productiveness. There is the great fundamental difference. Do all who are engaged in our peaceful, beautiful life-cheering and health-giving art, always act prudently and—yes, the word must come—mercifully? We shall, perhaps, see its applicability before the season's activities, now commenced, are over.

What is the necessary personal equipment of those who shall take a creditable part in our campaign? It can only be regarded as in any sense complete by the combination of a variety of acquirements. In addition to a good general education and technical knowledge, professional gardeners need to possess active powers of observation, with keen reflective faculties for the clear appreciation of cause and effect. They must cultivate the habit of watchfulness and the invaluable attribute of foresight; then, when imbued with a spirit of devotion to duty and promptitude in action, as occasion demands, they will not often be taken by surprise by the various "happenings" that are incidental to their vocation, and which, when not provided for, often have such prejudicial effects.

Take the case of supply and demand; no matter in what department, the fully equipped intellect of man will formulate a plan of operations by which the object in view will be achieved, because he will anticipate obstacles and provide for them, so as to minimise, if not nullify, their effects. He will neither rush into action precipitately with one thing, nor lag behind with another, thus incurring failure with both, but take careful stock of the means at disposal, and of prospective contingencies, will shape his course on the only safe lines that can be relied on to attain the end desired. A man thus equipped obtains what is required in the best form producible under the circumstances, and at the time it is needed; and why? Because he is a good general.

The trained, thoughtful, watchful gardener, be he amateur or professional, is quick to perceive what may be termed the tendency of symptoms. When this tendency, though apparently small in itself, is seen to be in the direction of a prejudicial issue, he at once resorts to measures for checking developments that might otherwise culminate in misfortune. The prompt righting of small wrongs prevents great evils. If this principle were acted on in the management of fruit trees in their youthful state, how much of after surgery, or rather fruitless butchery, would be prevented. The same principle holds good in all gardening affairs, and not least in that important duty of combating the natural enemies of those plants and crops we are seeking to produce. "Blunders in the field" is a phrase that runs glibly from the pens of armchair critics, who rest in security far beyond the zone of danger to themselves. There are blunders in the garden—real blunders—known to most men who have long been engaged in it, and not unknown to the present writer, for, truth to tell, he has been both a culprit and a victim. One of the greatest of these, and most common, as well as the most senseless, ruinous, merciless, costly, and even cruel, is the deep rooted, stupid, not to say lazy, habit of apparently watching the steady aggregation of insect scouts. Few at first, they are not thought worth troubling about. In far too many instances they are regarded with impunity till they become a formidable army of many legions before any serious attempt is made in subjugation. Destructive work has then been done by the horde of invaders, which are themselves then most difficult to destroy. Think of it all, and then surely condemnation must follow such miserable tactics.

Think of the filthy stunted plants—of the crippled growths of fruit trees, Vines, and Roses injured beyond restoration. Look at them and shudder. Grieve over them and pity their sad state. Then see those "ropes of bug," those "swarms of spider," those "colonies of thrips," those "piles on piles of lice"—aphides. If you travel far or into many gardens you will not have long to wait and be disgusted. Think again of the anxiety, the disappointment, the loss incurred, and of the frantic efforts made at last to conquer and to cure, but made alas! too late.

Once more, think of the waste of time and materials—money—in

the great slaughter, of the life encouraged to be (who) can say painlessly) changed, through writhing and horrible contortions, into death. It is positively cruel, and the more so because needless, but not cruelly intended, for truth lurks in the old couplet—

"Evil is wrought by lack of thought,
More than by want of heart."

That such evils in all their enormity as above described are preventable by early rational action is known to very many readers of these lines besides—AN OLD CAMPAIGNER.

An Australian Arcadia.

ONE of the most beautiful portions of New South Wales, if not of Australia, is that watered by the Clarence, so called after the duke of that name, in the northern part of the colony. "The Lovely Clarence," as the settlers along the banks of the magnificent stream are proud to call it, is the noblest stream of a noble family. It is the highway of traffic for an immense tract of remarkably productive country, and the principal avenue of commerce in the most important sugar-growing district in the colony. Communication with Sydney is chiefly by coastal steamer, a tri-weekly service between Sydney and Grafton, and the towns which dot the river bank, being maintained all the year round.

From the heads, forming the entrance to the Clarence, to Grafton is a pleasant run of about forty miles through scenery of the most entertaining character. The broad expanse of the Clarence, here running out into an arm eight or nine miles wide, and a little further on narrowing down to a mile, fully justifies the pride the farmers take in their magnificent stream. The rich alluvial flats, with their waving fields of Sugar Cane running down to the water's edge, the homes of the farmers all along the banks, the sugar mills with their huge chimney stacks, the islands, clothed in the most luxuriant semi-tropical foliage, which dot the stream all along its course, forms one of the prettiest and most satisfying pictures that could be imagined, the scene being completed by the graceful undulating hills, with their virgin forests, which skirt the fruitful plains on the river banks. Here the cruel hand of the drought fiend never retards the work of the producer; and the rising of the flood waters over the smiling crops of Sugar Cane does little harm beyond causing some inconvenience to those who have to seek higher ground for the time being, while the inundation brings down a fresh supply of Nature's fertiliser from the hills, and restores to the land what has been taken from it by a series of bountiful harvests. The rainfall is plentiful, averaging about 100 inches in the course of a twelvemonth, while, save for about four months in the year—two at the height of summer and two at the depth of winter—the climate is spring-like, and vegetation of all kinds thrives the year round.

The farmers' homes are the embodiment of comfort. One never sees the bark humpy on the Clarence, and there are no tumble-down cowsheds or dilapidated barns. The houses themselves are rather pretentious and ambitious. Mostly of weatherboard, with iron roof, the farmer takes a pride in his house, just as he does in the river, which he considers his own; the plot of garden is well kept and paled off, the house is painted, for the double purpose of preserving it and adding to its air of comfort; and if there are any barns or cowsheds which may in course of time become eyesores, by reason of their state of disrepair, they are judiciously out of the range of vision from the front verandah.

Grafton is a city that one would expect to find in a picture book, and one that is seldom come across in real life. It lies right down on the northern bank of the river, and spreads across the river under the name of South Grafton. Its streets are all avenues, mostly two chains wide, with a grove of trees on either side, leaving a clear drive of about a chain in the middle of the street, and of 12 feet to 14 feet between each kerb and the trees. There is an air of prosperity in every business house in the town. Empty shops are the exception, while some imposing establishments grace the main thoroughfare.

For years the cultivation of Sugar and Maize formed the staple industries, but the richness of the natural grasses and other favourable circumstances led to the introduction of dairy farming, which has proved an immense success, some of the finest butter and other dairy produce in Australia being furnished by the Clarence River district. Numerous agricultural crops are raised, and in the back country large numbers of cattle and sheep are depastured. Tropical and semi-tropical vegetation luxuriates in the fertile river flats. Oranges, Lemons, Bananas, Pine Apples, and Passion fruit all grow in abundance, but no attempt has been made to turn these fruits to commercial ends on a large scale. The whole yield of the orchards is consumed locally. Sorghum, Imphee, and Lucerne are cultivated, and yield abundantly, and, in fact, the climate and soil are congenial for the production of almost anything. Yet, strangely enough, the Clarence River district, the Australian Arcadia, is the one least known, not only to visitors to the Antipodes, but also to the great majority of colonists themselves.—J. PLUMMER, Sydney, N.S.W.

Two New Dendrobiums.

For several weeks the meetings of the Royal Horticultural Society at the Drill Hall have brought forth collections of Dendrobiums, some of which have been especially interesting for their rarity, and others for excellence of culture. On Tuesday, March 27th, the plants were much less numerous, quality taking the place of quantity. Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, exhibited *Dendrobium Melpomene* (fig. 76). It is the result of a cross between *D. signatum* and *D. splendidissimum grandiflorum*. The prevailing colour is cream, deepening to canary yellow in the lip; the throat is deep crimson. It is an attractively beautiful flower, and was recommended for a first-class certificate by the Orchid Committee. A similar honour was given to *Dendrobium nobile album* (fig. 77), which was shown by Mr. J. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford. This is an exquisitely beautiful pure white variety, the form of which is shown in the illustration.

Albino Forms of *Dendrobium Wardianum*.

Those who imagine they have the true albino form of *D. Wardianum* should note that in it the lip as well as the other segments lose all traces of the crimson purple tint, and though it may not be more beautiful than the type it is certainly more rare. Those forms without the purple tips to the sepals and petals, but with a normal lip, are equally pretty, but according to my experience they are apt to revert to the normal type in a mild and rather washy form. At any rate it is well to let the plant flower twice at least before setting it down as a true albino.

Dendrobium Johnsoniæ.

There are few more beautiful Dendrobiums than this, and everyone who flowers it is charmed with the chaste and delicate blossoms. It has that graceful outline, too, that is wanting in those otherwise fine kinds, *D. formosum* and *D. infundibulum*. "I wish I had a houseful of it," writes a correspondent, who grows Orchids rather largely in the Midlands; and there are many others of a similar opinion who are increasing their stock of it. Like many others in the section to which it belongs, it is not everywhere a success; but where its wants are properly catered for, few who grow Dendrobiums at all will go far wrong with it.

The plant is only of moderate habit, so it is useless to expect it to thrive in large receptacles, such as suit the grosser-growing kinds,

FIG. 76.—*DENDROBIUM MELPOMENE*.

and as much of its growth is made during the dull season it is advisable to keep it well up to the light. The small pans for suspending are excellent for it. Sun heat and ample moisture are the conditions the Australian Dendrobes delight in, and this fine Orchid as much as any. The nomenclature is a little confused with regard to this plant, *D. Macfarlanei* being a synonym. It is a native of Torres Straits, and was discovered by Mr. Hartman.

Odontoglossum Ruckerianum.

The soft and delicate colouring on the segments of this charming Orchid will appeal to all lovers of this genus. In habit and all other characteristics it is very similar to *O. crispum*, and, like it, it delights in a cool moist temperature all the year round with ample light during our dull sunless winter, and close shading to keep down the heat of summer. Many forms distinct from the true *O. Ruckerianum* are labelled as such; indeed, it is not so common as many growers imagine. The sepals are prettily margined with rose purple, and the lip has a large blotch in front. There are several excellent varieties of *O. Ruckerianum*, and amongst them *O. R. splendens* (fig. 78, page 283) occupies a leading position.

Odontoglossum Rossi rubescens.

There is no more useful *Odontoglossum* than *O. Rossi*, and this variety in its best form is one of the best of the rather large number included in it. The true *rubescens*, although only a colour variety, has broader outer segments and a more massive lip than the type, with reddish brown spots on a rosy ground. Like all the other

FIG. 77.—*DENDROBIUM NOBILE ALBUM*.

varieties it is very free flowering, and of the easiest culture in a cool, moist house, such as suits *Odontoglossums* generally. It should be grown in equal parts of peat and moss, and preferably suspended near the roof.

Angræcum citratum.

Many of the *Angræcums* belonging to the small flowered section are very beautiful plants, and I question if there is a better than this if all its good points are taken into consideration. The flowers are produced on pendulous racemes, and though the specific name refers to its colour this is usually absent in cultivated plants, most of them being pure white, though it is said to be citron yellow in a state of Nature.

Though this plant was discovered by that intrepid Frenchman Albert du Petit Thouars more than a century ago, it was not introduced to this country until many years after, the first recorded instance of its flowering being half a century later at least. It is a native of Madagascar, and should be grown in a strong moist heat, being preferably hung up not far from the roof glass. The small wood baskets are best for it, and failing these small pans. Ample supplies of moisture are necessary, but the compost should be so arranged that it passes easily and rapidly away. Light syringings in bright weather are helpful, but must not be overdone. Keep the roots on the dry side a little during winter and until the flower spikes appear.—H. R. R.

Oncidium Phalænopsis.

I READ with much interest the Orchid notes in the *Journal of Horticulture*, and as I cannot remember having seen during the past year or two any reference to this plant, I am sending a short note, as I consider it extremely useful as well as beautiful. *Oncidium Phalænopsis* is not a plant of robust growth, but it succeeds admirably in a cool house, which, in my opinion, is one of its greatest recommendations, as it can be accommodated with the *Odontoglossums*, and any really good addition to the cool Orchid house is always welcome. The individual flowers are not very large, but as several are borne on a spike this should be no disadvantage. The ground colour is pure white, and the whole of the markings, in the form of dots, spots, and bars, are of a peculiarly bright bluish-purple or violet tint. It is an Orchid that deserves extended attention from those who admire chastely beautiful flowers.—S.

Hardy Flower Notes.

HEEDLESS, perhaps, of past experience, a little while ago we might have fancied that winter had gone for the garden year, and that we were fairly over the threshold of spring. Our hopes were vain, for frost and snow have again returned to mock our dreams and to retard our flowers. As this is written, when March has almost gone, the snow yet lies on the hills which bound the horizon, and nightly frosts are severe, bringing with them the strain on plant life which comes from the sharp contrasts between the bright sunny days and the keen air of the night. It is now that one trembles for the safety of some flowers, and longs for the smiles and tears of April. These will come in due time, and ere this is in type, and meanwhile we must be content with the beauty of the present time. After all, one has little reason to complain, for letters from some not so far away tell of tardy flowers, hindered from coming at their usual time by the obduracy of the winter's movements. When one hears, as to-day, of a garden in which *Crocus Imperati* has just opened, and where only one Daffodil has bloomed, one feels that, after all, one's lines are cast in pleasant places. If we look round we shall see no meagreness of bloom to make us grieve.

Though the number of Daffodils in flower is not large as yet, the beauty of those in bloom gives us some delightful moments as we look at them and strive to absorb into our minds their graces of form and colour. It is the Trumpet Daffodil which now calls forth our admiration because of its marvellous attractiveness. If we study it closely we are the better able to enjoy its graces of silver and gold. The tiny little *Narcissus minimus* has lasted long. Though the first blooms show signs of wear and tear, those which have succeeded them are yet fresh and fair. The little minor and lobularis have come as well, and droop from the stems with all their wonted beauty. In its appointed place in the rock garden we have besides the rich golden yellow of cyclamineus major, whose long trumpet looks so quaint because of having its perianth segments turned back like those of the Cyclamen or the Dodecatheon, instead of standing like a frill around its base, or half-enveloping it in hood-like form, as some do. The first blooms of *N. pallidus præcox* grow a little paler as age begins to tell upon them, but later varieties of the same species are only now open or are on their way to join in the pleasing contest for the palm of beauty among the rival Daffodils. The Saragossa Daffodil is again among the earliest, and gives one full pleasure by its opened blooms of pale yellow gradually deepening to the extremity of the trumpets. The first deeper yellow bloom of that fine *Narcissus*, Mrs. H. J. Elwes, is only open to-day, but the shades of yellow which show from other Trumpet Daffodils tell us that we shall not have long to wait for a full revelation of the charms of the flower of the spring. The glory of the present lies, however, with the *Crocus*, though one must say little about it now in view of what was said by the writer so short a time ago. The glorious golden-yellow *Crocus* yet makes a brave display, and it has a gallant band of Dutch *Crocus* to be its vanguard, or, better still, as more appropriate in point of time of bloom, its rearguard. Many of the *Crocus* species have lost their holiday attire, and in sober green prepare for their long rest beneath the ground.

There is much delight to be found among the other bulbous flowers. To the bulbs, we who love to have early flowers in the open air, owe a deep debt of gratitude. What should we do without them to make our gardens bright and cheerful? Their hardiness and their charms are both passports to our affections, and, as years go on, the increasing numbers show us even more of their beauties than the few bulbs with which the stock may have begun. Of what shall we tell first in the necessarily short survey of the hardy flowers of the time? The Snowdrop is not yet over, though fast hastening to its resting time. The Glory of the Snow is with us still in its several forms. *Chionodoxa Lucillæ* has as its companions now the deep blue *C. sardensis*; the fine *C. Alleni* (if this is distinct from *gigantea* or *grandiflora*, which I rather doubt); the deep coloured *C. Tmolusi*, whose flowers have a tinge of purple; with the various forms of white or rose, which selection and seedling raising have given us from different species. The little *C. nana* is the latest and does not yet show colour.

The affinity between the Scillas and the *Chionodoxas* is shown by the presence of some of their hybrids, the *Chionoscillas*, with flowers between the two, but in some ways even more useful for distant effect. The Scillas as represented by blue, white, flesh, and pink varieties of *Scilla bifolia* are of much interest too. *Scilla sibirica* also gives its offering at the shrine of spring in the shape of its pretty flowers, which spread their petals to the bright sun, though too modest to upturn its flowers to its ardent rays. On the rockery we have as well the pretty blooms of the *Puschkinias*, with their pale, almost white, clustered blooms lined with blue. The latest Snowflakes join in the floral offering. *Saxifraga apiculata*, once thought crippled for the year, has, after all, given us a good display of its pleasing

sulphur-yellow flowers, and near at hand the deeper yellow *Saxifraga sancta* is bright with the smaller blooms it gives upon their uplifted stems. A change of colour is given by the varieties of *Saxifraga oppositifolia*, with purple or white flowers. The freest flowerer on the dry soil of my garden is *S. rudolphina compacta*, a neat dwarf plant, as indeed are all the others of the same section.

The Winter Heath, *Erica carnea*, is yet a mass of bloom, and its attractions for the bees seem to try to their utmost the loyalty of their attentions to the *Crocus* and other early flowers. In *Androsace carnea* we have an enjoyable little early flower for the choice rockery. Its small bright flowers are exquisite in the eyes of those who love these fascinating blooms, which have their wants best attended to in the rock garden among others of similar size. It is not very difficult to grow on a rockery where it can receive full sun, and also a plentiful supply of water in dry weather.

Perched on a rockery is the delightful *Rhododendron præcox*, said to be a hybrid between *dahuricum* and *ciliatum*. Its peach-coloured blooms are always welcome as the precursors of the other dwarf *Rhododendrons*, as well as for the beauty they themselves display. Would that the frost would be less disposed to take the colour from the flowers, and would not cause us to screen them from its power by covering at night with a hand-light. Not far away the earlier flowers upon *Lonicera fragrantissima* look a little sad because they have not received similar protection. The Lenten Roses, too, have suffered somewhat, and many are useless for the year.

Our tale is thus spun of threads of pleasure and of disappointment. Truly the garden of all seasons is a picture of our lives and their pursuits. I have, perhaps, been too mindful of the disappointments, as another walk in the garden ere the closing line is penned shows flowers other than those of which I have ventured to speak. It is always thus—the pleasures of the garden are inexhaustible to those who can view them aright.—S. ARNOTT.

The Culture of Primulas.

AMONG plants that produce abundant bloom during the early part of the year Primulas must take an important place. They are cheerful and attractive in colour, producing not only imposing heads of bloom, but large individual flowers, especially the single varieties of *P. sinensis*. The plants of both single and double sorts are readily raised from seeds. The latter, however, are not so perfectly double as the florists' varieties, these being named sorts and annually increased by cuttings. In addition to the single and double forms of *P. sinensis* there are the Star Primulas, or *P. stellata*, and *P. obconica*, the latter having lilac coloured blooms, the former blooms of various colours.

As regards raising these varieties from seed, the method and treatment are the same, as is also the subsequent culture throughout the summer and autumn. April and May are the best months for sowing Primula seeds, and if the strain is obtained from one of the leading firms who make their culture a special feature, and give unremitting attention to the task of maintaining the strain at a high standard, the result will be satisfactory.

I find 5 or 6-inch pots quite as suitable as pans or boxes for seed sowing. The pots must be clean and well drained. Fill them a quarter full of drainage, employing crocks of various sizes, the larger at the base, the smaller at the top. On them spread a layer of damp moss, then fill up with soil. This must be carefully prepared. Pull some fibrous loam quite small, and add an equal quantity of sweet leaf soil passed through a riddle to free it of small stones and sticks. Then intermix a liberal quantity of silver sand and crushed charcoal, thoroughly incorporating the whole. It must be in a moist condition, though not wet. Fill the pots to the rim and jar the soil down to a level mass, half an inch below the rim. Water the soil with tepid water applied through a roset can, allow the pots to drain well, and then sow the seed evenly on the surface. Just cover with a thin layer of sand. Place the pots in a temperature of 65°, and plunge if possible over some bottom heat.

A propagating frame is, of course, the best, sinking the pots to the rim in cocoa-nut fibre refuse; but failing this, introduce similar material into a large pot and sink the seed pot in this, standing the larger pot on hot-water pipes for obtaining the requisite heat. Cover with a pane of glass, and over that a sheet of paper, removing the latter when the seed germinates. Plunging the pot in a moist medium, and preventing rapid evaporation by protecting the surface soil from the drying influences of abundant air, are the best means of maintaining the requisite moisture in the soil without having recourse to watering before the seed germinates. When germination does ensue afford plenty of light to prevent the seedlings becoming drawn,

placing the pots on a warm shelf, and admit air by tilting the glass. When the seedlings have gained strength dispense with the latter, but the pots may remain plunged in a larger one until the time arrives for pricking out. This can be done in pans or small pots. The latter seem to be the best for subsequently easily dividing. Use similar compost to that for sowing, and place not more than three seedlings round the edge of 3-inch pots. Sink the seedlings down to the base of the leaves, which will materially assist in strengthening them. In pans or boxes give a space of 2 inches asunder. To place them closer results in the leaves growing too closely and crowding the plants, preventing that sturdiness which more space insures. A little heat and moisture will give them a start, which, on being assured, permits of assigning the plants a light position on a cool airy shelf in the greenhouse.

The next process consists in placing the plants singly in 3-inch pots, which should be efficiently drained. Prepare the compost with rather less leaf soil, but add a little well pulverised manure to the materials recommended previously. In potting secure the full share of fibrous roots belonging to each plant, and place low down, so that the plant rests securely on the surface of the soil. Make the compost firm, but not hard. Frame culture may obtain now, standing the pots on a moist base and near the glass. Water carefully at first, increasing the

Reminiscences of An Old Florist.—No. 6.

ALTHOUGH the Rose was the main object of my visit to France with Mr. Standish, and although for many years I was in the habit of making an annual visit there, it was not the only flower which attracted me thither; I had been for many years an admirer of the *Gladiolus*, and it was on the occasion of one of my visits that a kind friend said to me, "As you are fond of the *Gladiolus* you ought to go and see M. Souchet at Fontainebleau."

M. Souchet at the time held the position of chief gardener at the château—a château inseparably connected with the beautiful and extravagant Diana of Poitiers, who had left her mark in well nigh every room in the building. Most of the French monarchs of later years have occasionally made it their residence, and in point of historical incidents there is perhaps none of the royal palaces of France more full of interest. The gardens were laid out in the formal style so beloved in France, and of which Versailles and St. Cloud form perhaps the most notable examples. I do not know exactly when Souchet took up the hybridising and culture of the *Gladiolus*, but I think it must be more than half a century ago; at that time there was little done with it in England, and in fact the whole culture in France was of a peculiar character, for although a very few other cultivators appeared for a while on the scene, they gradually retired, and anyone who wished to obtain any roots had to do so through other sources, especially that of Messrs. Vilmorin, and the roots are, I believe, all supplied from Fontainebleau.

This visit paved the way to a long and lasting friendship, which only ended with the death of my revered friend. He was one of the most genial and pleasant of men, and though suffering from a very sad complaint, his serenity and cheerfulness were always unruffled; and it used to be one of my great anticipations as summer came on that I should once more see him. What stories he used to tell about the difficulties he experienced in the cultivation of his favourite flower. His greatest trouble arose from the larva of the cockchafer, or *Ver blanc*. The perfect insect appears in May or early in June, when it deposits its eggs in the soil, and after the larvæ are hatched they burrow beneath the surface, where they continue in the pupa state for three years. During this time they work untold mischief on every kind of produce with which they can come in contact. Souchet used to employ an army of women and girls to collect the perfect insects before they had time to begin their work of depositing the eggs. He has told me that bushels upon bushels of these pests were collected and destroyed every year, their numbers being much increased by the nearness to the forest. I have seen at Versailles, at Truffaut's nurseries, whole quarters of *Wellingtonias* completely killed by these insects barking the young trees.

However, Roses were after all the chief object of my visit, and every year I was able to bring back some definite information concerning those that were likely to be brought forward. There are one or two noticeable incidents in connection with these visits. Intelligence had been brought to us that Lacharme, to whom we are indebted for some of our best Roses, had raised a yellow Hybrid Perpetual. Now, as this was one of the great desiderata of the Rose world, on mentioning it to a London nurseryman he authorised me to offer a good round sum for it. Alas! however, when I got to Lyons I found it was all a myth! It was true he had found in one of his seedlings a slight tinge of yellow at the base, but this vanished as the flower opened, and it was simply a white Rose. On leaving Lacharme's nursery I went to Guillot's (young Guillot, as we used to call him then, though he too has passed away, and the Guillot of the present day is his son). On going over his garden we came to one Rose tree, and he said, "I think this is the beginning of a new race, and I expect great things from it." It was indeed a great beauty, very sweet, and really one of those Roses which, like good wine, needs no bush. I was so struck by it that I ventured to offer him the sum which I had been authorised to offer for the yellow Rose, thinking it would have tempted any French nurseryman. Guillot, however, wished to have the honour of sending out this new Rose himself, and probably there has been no more popular Rose than *La France* (for it was that Rose), which he sent out as a Hybrid Perpetual, but which after some years was placed in the class for Hybrid Teas.

Another incident was my first introduction to Maréchal Niel. M. Eugène Verdier brought to me one morning at my hotel in Paris a box of Rose blooms. They were of various shades of red and crimson, but though pretty did not seem to me anything remarkable. Glancing at the box I remarked, "But what is that?" "Oh, that is a yellow Rose," he replied, "which came from the south." "Then," I said, "that is worth all the rest of the Roses you have brought put together." I advised him to keep it over for another year, bring over a box of blooms at one of our exhibitions or to the R.H.S., and added, "I venture to say you will reap a golden harvest." There were,

FIG. 78.—*ODONTOGLOSSUM RUCKERIANUM SPLENDENS*. (See page 281.)

supply as the plants become established. The frame should be stood, if possible, on the north side of a wall, which will obviate the necessity of shading from the sun, but if in other positions shade during the midday hours must be given. A free circulation of air is also of importance.

The final potting may take place from this size pot, 3-inch, employing 5 or 6-inch according to the strength of the plants. Loam, leaf soil, decayed manure and sand, with a proportion of crushed charcoal will form a suitable compost. See that the plants to be potted are thoroughly moist, as it will be a difficult matter to moisten the ball of roots afterwards without unduly saturating the new soil. Employ efficient drainage in the pots. Place the plants low down, and work the compost carefully round the ball, filling it up to within half an inch of rim of pot. It may be made firm, but not hard. Stand the plants back again in the frame on a moist base of ashes, and for a week or so keep the frame close. Afterwards give air in increasing quantity as the plants become established, drawing off the lights entirely on favourable occasions. If the sun reaches the frame at midday shade must be given.

In September the plants may receive full sun. At all times carefully water, keeping the heads as near the glass as possible. At the end of September remove to shelf in greenhouse, where they may remain until flowering commences. At that period weak supplies of liquid manure will be beneficial in strengthening the flower spikes and intensifying the colours of the blooms. During midwinter, however, liquid stimulants are not needed quite so often.—E. D. S.

however, some trade complications which prevented this. I was not wrong in the estimate I formed of *Maréchal Niel*, and although I think it must be mainly considered as a Rose for the house, yet it is perfectly hardy, and unquestionably one of the most popular Roses that we have.

I attended several Rose exhibitions in France, but have been utterly disappointed with them. One great mistake they make is to attempt to get together too large a number of flowers; prizes for 250 are frequently offered, and when these are brought to the exhibition they are so arranged as by no means to show forth their beauty. Again, let me say that one never sees at a French Rose show flowers that can at all compete with those that carry off the premier prizes at our national shows. I think that this is, in a great measure, due to the wish not to incur expense, and to the entire absence of amateurs, for amateurs, like some of our largest growers, are entirely wanting in France.

Another visit which is strongly marked in my memory is one that took place a good many years ago, how many may be gathered from the fact that it occurred when Mr. Bowles was manager at the Crystal Palace. There was to be an exhibition of bouquets, and he was anxious that it should be an international one. We heard a great deal of the artistic arrangements of hand bouquets which prevailed amongst the *bouquetières* of Paris, and he was anxious that the British public should have an opportunity of seeing what they could do. He therefore asked me if I would try and arrange it for him. I did so, and with a great deal of trouble carried it out. I went to Chévet in the Palais Royale, to another florist in the Boulevard des Italiens, and another in the Boulevard Poissonier. They were not limited as to price. I had a good deal of trouble to get them to my hotel in time, and starting by the night mail, we arrived at the Crystal Palace in time. The whole thing was unfortunately a disappointment, and forced upon us all the conclusion that our English florists were no way behind their French compeers; in fact a good many illusions of this kind have been dispelled by our better knowledge of France and its ways.

Many English people will have an opportunity this year of visiting the French capital; they will be able to learn much of French horticulture around Paris. Let them, however, avoid two errors: First of all not to think everything French must be good; and secondly, not to think that we have a superiority in everything. There can be nothing more offensive than the contemptuous manner with which many English tourists regard everything French. Of course my travelling days are now over, but I shall always look back upon my visits to France as times when I learned a great deal in horticulture and enjoyed myself much. I suppose that my French extraction had something to say to the pleasure I experienced, for whenever I told people about it the welcome I received was still more cordial.

But my visits abroad were not confined to France. I went several times to Belgium; I visited M. Linden at Brussels, and Verschaffelt, Van Geert, and others at Ghent. This is a wonderful city for horticulture, but I was never able to be there at any of their quinquennial shows, for, unfortunately they always began on Sunday. In many of these Azaleas, Camellias, and foliage plants were cultivated with great success, and it was wonderful how cheaply these plants were produced and how hundreds and thousands of them were turned out exactly like one another. We see the same now amongst our market gardeners in the neighbourhood of London; Fuchsias, "Geraniums," and other plants are turned out as if from a mould. There were, however, no such attractions for me in Belgium as were afforded by the Roses and *Gladiolus* in France, although in the case of the latter flower the large number of the beautiful varieties raised by Souchet and his successors owe their origin to Gandavensis, which, as I said, was (as its name implies) raised in Ghent.—D., Deal.

The Royal Horticultural Society.

Scientific Committee, March 27th.

Present: Dr. M. T. Masters (in the chair); Mr. E. F. Im Thurn, Mr. Michaels, Mr. Hudson, Dr. Russell, Mr. A. Sutton, and Rev. W. Wilks.

Fringed Cyclamen.—Dr. Masters exhibited from the collection of *Cyclamens* brought by the St. George's Nursery Co., Hanwell, to the Drill Hall, a leaf of their fringed *Cyclamen*, in which not only the flowers were fringed but the leaves were deeply lobed, and the lobes themselves were lobulate and bilobulate, the ultimate lobules being irregular in size, and, in some instances, shortly stalked, thus presenting an appearance similar to that of curled Parsley or of some of the varieties of *Scolopendriums*. It was stated by the raisers that the sub-

division of the leaves was observed originally on plants bearing flowers of the ordinary character, and subsequently on those which had fringed flowers. Continuous selection through some seven or eight years had, at length, resulted in the production of plants in which the foliage and the corolla were equally deeply fringed.

Rose leaves.—Some Rose leaves were sent for an opinion. They had been grown under glass, and presented no appearance of insect or fungus; but were thin in substance and partially destitute of chlorophyll, showing that the nutrition of the plants was impaired, but from what cause could not be ascertained.

Vine leaves, diseased.—With reference to the samples sent to the last meeting from Gunnersbury, it was stated that in the opinion of Mr. Massee the appearances were consistent with the attacks of red spider or punctures of aphides; but reference to Viala's *Maladies de la Vigne* and Mr. Massee's Text-Book of Plant Diseases showed that the spots were probably an early condition of Grape-rot (*Glaeosporium*). The leaf-buds were observed by Mr. Massee to be infested with mites.

Viburnum with hypertrophied branches.—A specimen was sent by Mr. Richard Dean, who stated that the whole tree was covered, at intervals of a few inches, with globose, nodulated, somewhat fleshy excrescences, the size of a large Cherry and upwards. It was referred to Dr. William G. Smith for examination.

Growing Cockscombs.

CELOSIA CRISTATA, the Cockscomb, is a very old favourite annual. In offering a few remarks on the culture of these plants, let it be understood that the production of really good specimens depends more on the care and enthusiasm of the cultivator than any instructions he may receive.

Sow the seeds at once in pots, pans, or shallow boxes; place at the bottom a layer of potsherds, and the rougher portion of the compost over the drainage, which should consist of equal parts of loam and leaf soil, with a little silver sand. The seeds should be sown as evenly as possible, but not too thickly, covering with about one-sixth of an inch depth of the same soil finely sifted, plunge them into a hotbed, and give a little tepid water; place a square of glass over the pans or pots, and it should not be removed until the young seedlings touch it, and at no time allow them to suffer by want of water. As soon as they are large enough to handle transfer them singly to small pots, employing well-enriched soil—namely, light turfy loam, leaf soil, and well-decayed manure in equal parts, with sufficient sand to make the whole porous—and plunge them in a hotbed close to the glass, and shade from bright sunshine for a few days, at all times choosing a gentle warm day for potting, taking care that they do not receive a check from cold.

The plants will grow freely, and before becoming root-bound transfer them to 5-inch pots, employing the same compost as before, but adding a few finely broken oyster shells. Return them again to the hotbed and plunge them near to the glass for a time. Shade during the hottest part of the day, and close the frame or structure early in the afternoon. Be careful never to allow the soil to become too dry, or failure will result. It is the chief cause of stunted plants and loss of foliage, and nothing shows defective cultivation so much as plants with long stems devoid of foliage.

Cockscombs must be encouraged to grow uninterruptedly. Immediately the 5-inch pots are filled with roots, shift the plants into pots 9 or 10 inches in diameter. Be very careful about the drainage, especially those for late blooming, as in the dull days of autumn they are apt to decay at the neck if not well drained. Place a thin layer of moss over the drainage, with a sprinkling of soot to prevent worms entering the pots. Again assign them to the hotbed; plunge them near the glass, shading in sunny weather for an hour or two during the heat of the day, for if exposed to a scorching sun immediately after potting, the plants will lose their lower leaves.

When the flower-heads are showing, liquid manure may be supplied. About a handful of guano to a can of 4 gallons of water is an excellent stimulant; but it is not advisable to supply it too freely, as the premature decay which is attributed to damp is more often the result of overfeeding with liquid manure. When fully grown the plants may be gradually hardened and placed in a light well-ventilated structure, as a dry atmosphere is necessary; syringe occasionally to prevent the attacks of red spider. At this stage of their culture the greatest care must be taken to guard against excessive watering. If that is kept in view they will continue to be attractive for two or three months, and there are few brighter plants than well-grown Cockscombs. I have seen superb specimens, measuring from 2 to 3 feet from tip to tip of the comb, and as dwarf and compact as could be desired.—M. W.

NOTES & NOTICES

Recent Weather in London.—Intensely cold winds with brilliant sunshine at rare intervals and occasional night frosts have characterised the weather in the metropolis of late. Tuesday morning brought a decided change to milder conditions. There was little wind, and a gentle rain fell for some time, increasing to quite a downpour in the evening. At the time of going to press on Wednesday it was mild and dull.

Weather in the North.—Throughout the whole of the week ending the 2nd inst. frosts of from 4° to 6° have occurred nightly, and the days have been bright with an occasional duller evening. Farm work is being pushed on under favourable conditions, but vegetation makes little progress.—B. D., *S. Perthshire*.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, April 10th, 1 to 5 P.M., in the Drill Hall, James Street, Westminster, when special prizes will be offered for Daffodils (see R.H.S. Book of Arrangements, p. 58). At three o'clock a lecture on "Some of the Plants Exhibited," will be given by the Rev. Prof. G. Henslow, M.A.

Newcastle Flower Show.—On July 25th, 26th, and 27th Leazes Park, Newcastle-on-Tyne, will be the venue for the flower show of the Durham, Northumberland, and Newcastle-upon-Tyne Incorporated Botanical and Horticultural Society. The secretary is Mr. I. B. Reid, Mosley Chambers, Mosley Street, Newcastle, who will send schedules and particulars to applicants. There are five and a half dozen classes, divided amongst various sections of growers and for different kinds of produce, and the prizes should prove sufficiently tempting to bring forward a large number of exhibitors of a very high average quality.

The Royal Horticultural Society of Southampton.—It is pleasant to learn that this important society, which has of late years had many difficulties to contend with, is now practically free, and will thus be better able to continue its work. The report for 1899 shows a most satisfactory advance. The dates of the summer show have been fixed for June 27th and 28th, on the Royal Pier, and the schedule comprises classes for Roses as well as general seasonable produce. There are about four dozen classes. The Chrysanthemum and fruit show will be held in the Skating Rink on November 6th and 7th, when a fine show may be looked for. There are five dozen classes, many with capital prizes, and it should not prove difficult for all sections of growers to find classes suited to their conveniences. The honorary secretary is Mr. C. S. Fudge, 17, New Alma Road, Southampton.

The Gardeners' Association of Ireland.—The members of the above society held their usual monthly meeting in D'Olier Street, Dublin, on Thursday, March 29th, when there was a large attendance of members, and the president, Mr. Collier, occupied the chair. After the usual routine was completed, Mr. McFadzean, The Gardens, Killakee, (Lord Massey's) contributed a paper on "Cottage Gardening." He desired to impress on architects and others, when designing their houses, to leave a much larger space than heretofore, in order that the cottagers may be able to live more comfortably; also, as an incentive to better work, their landlords should start a cottage show (a feature not common enough in this country), contributing prizes. The remaining portions of his essay dealt with the uses of fertilisers, cultural notes, and the crops most suitable for the cottager. Subsequently Mr. R. Weller, F.R.H.S., Crostanstown Farm, Newbridge, read a short paper on "Grafting." He started by explaining the various modes of grafting in general, and laid special stress on the styles time had sanctioned. He ventured the opinion that side grafts were the best for pot Roses; that when grafting fruit trees the factor of locality should be kept prominently in view, otherwise failure may be the result. The latter portion of his paper comprised a series of hints for the guidance of those who intend to master the art of grafting, so that their labours may not be futile. The two papers gave rise to a spirited discussion. After a vote of thanks was unanimously passed to the lecturers, the meeting was brought to a conclusion. Mr. Hall, secretary, was in attendance.

Light.—In resuming his lectures on Saturday at the Royal Institution on "Polarised Light," Lord Rayleigh specially dwelt on refraction with all its remarkable phenomenon of varied colour. As the physiologist deals with the minute details of nerve and tissue, or the chemist in resolving the most complex body into its constituent elements, so has this expositor on optical physics gone into the most subtle properties of crystalline colour, analysing everything in connection with it, demonstrating its strictly scientific aspect by a series of most exact and pertinent experiments. Special reference was made to the theories and discoveries of Sir George Stokes and Mr. Madden. After hearing these lectures from the Royal Institution professor of natural philosophy the student can only come to the conclusion that, while the laws of Nature abound with evidence of the most supreme wisdom of their Author, the scientist in revealing these marvellous facts is indeed an apostle of veritable truth.

New York Nursery Inspectors.—Certificates of inspection of nursery stock have been issued by the Department of Agriculture at Albany to nearly 500 nurseries in New York State during 1899. These certificates are good up to and including June 30th, 1900. The inspectors found, says an American contemporary, that the San Jose scale has not increased appreciably in 1899, and are under the impression that it is on the decrease. There have been about 43,000 nursery stock destroyed this year, about 70 per cent. of this number being confined to one locality. The western part of the State is comparatively free, there being only three or four instances where it existed to any extent, and the stock was entirely destroyed. There are in the State five inspectors, men who are taken from the civil service eligible list, after having passed an examination for the position of nursery inspector. There is now before the legislature a bill amending the law, so as to have fumigating applied to all stock raised within the State as well as to all stock brought from without the State.

Hull and East Riding Chrysanthemum Society.—It is regrettable to learn from the committee's statement that there continues to be a falling off in the receipts of this excellent society, and we trust that the year 1900 will prove the turning point to a period of renewed prosperity and usefulness. Few societies have done more than this during the past fifteen years to popularise the Chrysanthemum, and it is deserving of generous support. This year's exhibition will be held in the Artillery Barracks, on November 14th and 15th, and a schedule of half a hundred classes has been arranged. These include, in addition to the celebrated group section, excellent prizes for incurved and Japanese cut blooms, £40 being offered in two classes for these. Silver cups and pieces of plate are added to the premier awards in several classes, and there is practically sure to be splendid competition. What the society really requires is a very much increased list of annual subscribers. Messrs. E. Harland and J. Dixon continue to officiate as hon. secretaries.

Chester Paxton Society.—The last meeting for the winter, session was held in the Grosvenor Museum on Saturday, when Mr. R. G. Waterman of Woolton, Liverpool, delivered a lecture on "Exhibition Roses." The lecturer is well known throughout Lancashire and Cheshire as a successful exhibitor of the "regal flower," and his remarks on this occasion were characterised by a thoroughly practical knowledge of his subject, which he freely imparted to his hearers. Minute details of the best varieties to grow, soil and situation, mulching, pruning, staging for the exhibition, table, as well as the treatment of pests which Roses are subject to were given. Incidentally he said that the gratitude of all those who appreciated really good Roses was due to the Pauls, Dicksons of Newtonards, Bennett, Piper, Cranston, Lord Penzance, and others who have done so much in the way of hybridising and raising new varieties. To the Very Rev. Dean Hole, Rev. H. D'Ombrian, Wm. Paul, and other writers on Roses, he said our thanks were no less due. In his closing remarks Mr. Waterman said that much as his success had been with the Hybrid Perpetual varieties, he nevertheless pleaded for an extended cultivation of the old fashioned garden Roses as well as the new simple varieties now popular with so many, and said he hoped that Rose societies would in the future recognise these more fully in their prize schedules. An interesting and profitable discussion followed, in which the chairman of the meeting (Mr. Thomas Weaver), the president of the society (Mr. Robert Wakefield), Mr. Hawkins, and Mr. J. Weaver took part. In proposing a vote of thanks to the lecturer, Mr. G. P. Miln emphasised what had been said about the old fashioned and simple varieties of Roses, and said that the presence of these was an added adornment to any garden. This vote of thanks was carried with acclamation, and a similar compliment to the chairman brought the meeting to a close.

Gardening Appointment.—Mr. Chas. Ford, for two years foreman at Coombe House Gardens, has been appointed head gardener to Henry Goschen, Esq., Heathfield, Addington.

Philadelphia's First Willows.—It is stated that the first Willow trees in Philadelphia (which grew on the site of the custom house) resulted from an accidental discovery on the part of Benjamin Franklin, who found a wicker basket, which had been thrown into a damp place, sprouting. He felt much interested, and gave some of the cuttings to Charles Morris, who planted them on his place. The stalks took root readily and thrived, and a number of Willow trees resulted.

Royal Bouquets.—In a description of the Royal saloon decorated with Shamrock on the occasion of her Majesty's memorable visit to Ireland, we are told that charming bouquets of flowers from the Frogmore gardens were provided for the Queen and Princesses. Her Majesty's consisted of Tea Roses, Lilies of the Valley, and Maidenhair Ferns. Princess Christian's was made of Orchids and other blooms, and Princess Beatrice's of Ghent Azaleas, Lilies of the Valley, and foliage. All were bunched in lace-paper holders. A vase of Violets was also placed in the Royal saloon.

The Profits of Market Gardening.—Numbers of inquiries come to the editors of horticultural and agricultural newspapers of gardening profits that may be made out of growing fruits and vegetables for market. Much attention is paid to the character of the soil, the climate, and the adaptability of varieties to these conditions; but one essential is over all, and that is the marketing of fruits and vegetables after they have been raised. Even when there are markets convenient a person may be wholly ignorant of the methods of marketing. It takes, says Mr. Meehan, nearly as much art to know how to sell as it does to know how to raise the article in the first place. In brief, the success of any proposed market garden plan depends as much on the man himself as on the natural conditions of soil and climate.

Workmen's Compensation Act and Agricultural Labourers.—On Tuesday the House of Commons Grand Committee on Trade revised the Workmen's Compensation Act, 1897, Extension Bill, Mr. J. Ellis in the chair. Mr. Walter Long moved that Clause 1 should read as follows:—"The Workmen's Compensation Act, 1897, shall apply to the employment of workmen in agriculture by the occupier of any farm or premises used wholly or in part for the business of agriculture, who habitually employs for hire one or more workmen, and any such occupier shall be deemed an undertaker within the meaning of that Act. The expression 'agriculture' includes horticulture, forestry, and the use of land for any purpose of husbandry, inclusive of the keeping or breeding of live stock, poultry, or bees, and the growth of fruit and vegetables, and the like. The expression 'workman,' in the case of agriculture, means every labourer in agriculture." At present the clause said that the original Act "shall apply to all employment on or in or about agricultural work, and a labourer in such employment shall be deemed to be a workman within the meaning of the Act." These words would, of course, disappear if his amendment were adopted.

The Red Book of Honour.—In this small manual with a significant crimson binding, and bearing the title "Who's Who at the War," we have chronicled by Messrs. Charles and Adam Black the names of only a part, alas! of those who have died and suffered for us in South Africa. The record includes commissioned officers killed and wounded to about February 20th last, but takes no account of the others of lower rank, or of those since included in the casualty lists. There is a talk of erecting in London some more imperishable record than that upon paper to the memories of our latest gallant slain. If so, it should be a temple in honour of the Empire, or better, the British Commonwealth now visible, and having on its walls the names of all who died in cementing that glorious political structure. No doubt the counties and colonies will do their best to immortalise the exploits of their own regiments, but in the metropolis should rise a Pantheon where in pictures, tablets, and scrolls should be perpetuated the names and deeds of those who have died in order that their motherland might be great. Westminster Abbey and St. Paul's are antiquated and insufficient. The Victorian Era should be commemorated by a British Valhalla standing on the new Embankment by St. Thomas' Hospital, and facing the Houses of Parliament.

Tree Planting on Welsh Crown Lands.—We are informed that her Majesty's Commissioners for Woods and Forests have again placed their order for extending their plantation on Crown property, Wales, in the hands of Messrs. Wm. Clibran & Son, under the superintendence of Mr. Lewis of Arthog.

Hampstead Heath.—This popular resort of Londoners has had another charm added to it on the Golder's Hill estate. This beautiful area exceeds 30 acres in extent, and was secured to the public for some £36,000. The estate is now vested in the London County Council, and becomes the property of the metropolis in perpetuity.

Engines Injuring Flowers.—A firm of nursery gardeners and florists, Messrs. Cull & Rook, carrying on business near Tottenham, on 27th ult. successfully brought an action against the Great Eastern Railway Company, to recover damages for injury to their business caused by passing trains. The case was tried by Mr. Justice Grantham and a special jury. In 1898 the railway company constructed a large number of sidings near Tottenham, and on these, the plaintiffs alleged, engines were constantly waiting, and the drivers took the opportunity to clean their boiler tubes, a process known as blasting. Black and greasy smoke, steam and soot, Messrs. Cull declared, pervaded their greenhouses, quite blocking the light. With the smoke was emitted quantities of sulphur, which mingled with the atmosphere to make a kind of sulphurous acid. This got into the greenhouses and damaged the plants. Defendants submitted that they had acted solely within their statutory rights, but the jury found for the plaintiffs, damages £400. A stay of execution was granted by the judge, pending an appeal.

Weather in Ireland.—The weather in the metropolis and adjoining counties is far from being pleasant. Since the slight return of the snow about a fortnight ago a reaction has set in, the days being cold with several frosty mornings. The rain, however, was of the briefest, only slight drizzling showers, and a complete absence of sun—that is, practically speaking, until Saturday the 31st. This was a pleasant day.

Sussex Weather.—The total rainfall at Abbot's Leigh, Hayward's Heath, for the past month was 0.83 inch, being 1.14 inch below the average. The heaviest fall was 0.44 on the 18th. Rain fell on five days. The maximum temperature was 56° on the 10th, the minimum 19° on the 18th. Mean maximum, 45.16°; mean minimum, 32.19°. Mean temperature, 38.67°—2° below the average. A dry, cold, sunless month. Vegetation backward, showing signs of a late spring.—R. I.

March Weather at Dowlais.—Total fall rain and snow 1.44 inch, which fell on eight days. Greatest snowfall 0.42 inch on the 18th; most rain 0.25 inch on the 9th; for the same period last year 2.22 inches on ten days; total for the first quarter 17.32 inches. Temperature: mean maximum, 40.451°; highest reading 50° on the 29th; mean minimum 24.709°; lowest reading 10° on the 17th; below freezing point on twenty-six nights; mean in the sun, 50.387°; highest reading 86° on the 12th. Sunless days twelve. The wind was in the N.E. and E. for the greater part of the month. Bitter, cold, and piercing winds prevailed until the last week, when it was very mild in the daytime, but sharp at night.—WM. MABBOTT.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

The weather during the week has been cold, dull, and dry.

Fruit Prospects and the Weather.

IN the south of Ireland we have had during the past month very abnormal weather. I cannot remember another March in which the temperature was continuously so low—hardly a single day even with the sun shining above 50°, and generally below 40°. The result is that the season is about a month backward. I have had Ashleaves and Snowdrop Potatoes planted in friable soil for a month, and they are barely moving. It would have been worse than useless to sow small vegetable seeds. Of much importance is how this state of things will generally affect the fruit crop prospects, and, perhaps you would invite the opinion of English and Scotch correspondents on the point. Here we are certainly a month behindhand. There is not a fruit tree in flower in my garden at the end of March. I have often had even such late varieties of Pears as Beurré Diel and Josephine de Malines in full flower at the end of February. There is a fair prospect of bloom upon Marie Louise, Clapp's Favourite, Beurré Bachelier, Williams' Bon Chrétien, Jargonelle, Louise Bonne de Jersey, and Conference, but Beurré d'Amanlis and Doyenné du Comice are not sufficiently forward to form an opinion yet. The same thing applies to Apples. Needless to say there is not even an Irish Peach Apple yet in blossom or likely to be for a fortnight. The earliest garden blossoms are generally Apricots—fully a week must elapse before either an Apricot or Nectarine blossom expands in my garden, and then only those partially protected against a south wall. So of flowers, Crocus, Snowdrops, Anemones, and early Narcissi are gradually expanding equally late. Admitting the danger from late frosts is thus minimised, is not all this encouraging for fruit prospects?—W. J. MURPHY, *Clonmel*.

Sparrows and Yellow Crocuses.

I HAVE no wish to enter into the controversy as to what induces the sparrow to destroy the yellow Crocus blooms in so many gardens, although from his conduct in other respects I should, notwithstanding his many attractions, be inclined to lean to the side of those who say that they are pure mischief. I wish to note the circumstances of my own experience, of which I can give no explanation. For many years I suffered annually from their depredations; each year as the spring arrived I watched the development of the borders of bright flowers in my garden, and I hoped that I should be left unmolested; but, alas! it was not to be, and I vowed vengeance against the whole tribe, which all ended in smoke, for I have neither shot nor trapped one. However, some years ago when spring arrived and the blooms were very abundant, and I looked of course for the arrival of my friends, but none came. There is a farmyard next to my garden in which they hold their parliamentary discussions and arrange their plans, and strange to say, whether the conservatives outnumbered the radicals or whatever was the reason, my Crocuses were left severely alone. Since that time I have never suffered as I used formerly to do. I can only think that some conservative orator amongst them denounced their proceedings and obtained a vote in my favour, and not a single bloom suffers.—D., *Deal*.

It is so difficult for me to assume that birds, in pulling or eating flowers, do anything wantonly. One might as well assume that when birds eat Peas, or Cherries or Pears, or any other fruits they are acting wantonly, and not because they seek food. Certainly the little holes tits make close to the stems of Pears that are unprotected seem to be wantonly made, as often nothing more is eaten, but that food is the object there can be no doubt. The Pear looks tempting at the time the harm is done, but the fruit, after all, is not sufficiently luscious to gratify the bird's palate, hence it passes on to another one, and again the same thing happens. Were the harm done "wantonly," or from pure love of mischief, we should then have to put the birds on a reasoning equality with boys who love to indulge in wanton mischief, because they know that some one or other will experience annoyance.

Could the Croydon sparrows read and understand the recent note from "B. K.," how they would laugh and chatter over his vexation. But they are just as innocent of doing him or his Crocuses "wanton" harm as they are of understanding his feelings when he sees his plucked flowers, or perhaps in the late summer his pecked Pears and Apples. It is not evidence to say that not a particle of the flowers cast on the ground is eaten. Seeing that invariably the flowers are bitten off near the calyx, it seems far more likely that the object of the injury done is to obtain the nectar or honey which may lie in

the base of the flower, and be it remembered of the Saffron Crocus, also, which is sweetly perfumed. What birds search for in these flowers they apparently find also in Primroses and Polyanthuses, which in places sparrows destroy wholesale, especially in the neighbourhood of buildings, where probably other sweet food is very much lacking in April.—A. D.

Pelargoniums and Geraniums.

REPLYING to "W. G.'s" note in last issue, I well remember the seedlings referred to, but am under the impression that *G. pratense* and not sanguineum was the supposed male parent, Mr. Lowe's object being to introduce "blue blood" into the Zonals. The cross has been frequently attempted (by myself among others), but always in vain, and I believe there is no authentic record of any hybrid between Pelargonium and Geranium. Some of the seedlings certainly differed most wonderfully from the seed parent Madame Vaucher, but I could never myself detect any blue in them, and I believe that they were merely the result of self-fertilised flowers, and were reversions to an ancestral type, as we afterwards took one of the most remarkable, to Chiswick, and found it almost indistinguishable from *inquinans*, one of the original species from which our modern race started.—CHAS. E. PEARSON.

Judges and Judging.

It is very apparent from the number of letters which have appeared that this is a subject of wide interest. One can see, too, that divergent views are held on the subject, though the majority of your correspondents favour the retention of the same judges year after year. Nevertheless, I shall hold to the statement published on page 179, as I do not think any of your correspondents have advanced any very strong arguments against it. It will, perhaps, be as well if I refer to the several letters, and reply briefly to any points raised therein.

Mr. A. Kingston was first in the field, and needless to say he strongly objects to any changes in the direction indicated, and brings forward in support of his case arguments that are manifestly unreasonable. I most certainly should not advocate the employment of a Rose specialist to judge Chrysanthemums, and did not hint at such a thing. I am by no means convinced that the judging by the same men at Chrysanthemum shows is always followed by good results. Both Mr. A. Kingston (page 199) and "An Ex-Secretary" (page 217) propound the same question as to whether the continued re-election of judges does not prove that the executive committees are satisfied. To this I would unhesitatingly reply in the affirmative, but I do not by any means think that entire satisfaction to the exhibitors follows as a natural matter of course.

Then your secretarial correspondent suggests that I should not like to stand back for another. This would be quite true if I could get no other engagements, but this ringing of the changes simply provides fresh judges for every show if such be desired, and I maintain it to be desirable in the best interests of societies, exhibitors, and judges. "An Old Provincial" (page 245) writes a most excellent letter, and though his views are in opposition to my own, I was delighted with the logically reasonable phrasing. So far as I can gather his great fear seems to be not in change simply, but in indiscriminate change. This I think he need not worry about, as committees, if they did commence to make changes, would use their utmost endeavours to get capable men.

It is a curious fact that "An Old Provincial" adopts in support of his position my chief reason for objecting to the same adjudicators year after year. He implies that they become familiar with one another's methods, likes, and dislikes, and are prepared to give and take. Just so; and in this very give and take comes the great chance of unconscious injustice to exhibitors. At practically all exhibitions we find the competition singularly close in many classes—so close, in fact, that the result hinges on the taste of an individual. This is all very well in the first year, but suppose, as is often the case, the competition between those exhibitors continues as keen in succeeding years, and the same judges officiate, and the decision is based on the same point, what must naturally result? Simply that exhibitor No. 2 is not getting his deserts, but is being unjustly dealt with, as in all probability another set of judges would reverse the positions.

That such a position as this has arisen cannot be disputed, and the advantage of fresh judges is obvious. There is a tendency in this constant re-election of the same judges year after year to create small monopolies, and these are not good for the public at large. No doubt personal feeling enters into the question of change, as some of the older judges may fear that if an established engagement failed them they would not get another. This I think to be a false premise, as the re-arrangement would simply mean that they would go to fresh places, to judge the products of different exhibitors, displayed in dissimilar tents or places, and the entire novelty would awake an added interest in their work, with the natural result that that work would be better, or at any rate more carefully done.—AN INQUISITOR.

Garrya elliptica.

THOUGH this Californian shrub cannot be described as particularly showy, it nevertheless is a plant that might well claim more attention

value of the plant, for these catkins are at that dull period much appreciated by everyone. They impart a distinct, singular, and interesting appearance, as well to the shrub that produces as to the garden that contains them. Where a south or west wall is being furnished with plants this *Garrya* may well be accorded a place, and a little protection may be fixed over it in very severe weather. This is

FIG. 79.—GARRYA ELLIPTICA.

than is at present given to it. The plant is an evergreen, and as most people know, has as its distinguishing feature long drooping catkins. These are produced in the winter, and herein perhaps lies the chief

rendered necessary from the fact that the plant is not perfectly hardy in this country, though it has been known to flourish considerably north of the Humber. One thing is quite certain, which is that this

Garrya will not thrive in a poor, imperfectly drained, soil. It is therefore necessary, prior to planting, to remedy any defect in the drainage, and at the same time to enrich the soil with good manure if this course seems advisable. Propagation may be effected by inserting cuttings in sandy soil under a hand-light late in the summer, or by layers in the autumn.

Referring to *Garrya elliptica* in the "English Flower Garden," the author says:—"A fine Californian evergreen and beautiful winter flowering shrub. In mild winters it begins to flower as early as December, and bears among handsome deep green leaves gracefully drooping, tufts of pale green catkins, which, if cut with the twigs, endure a long time in vases and are welcome in winter. Though often grown on walls, it is hardy and makes a dense bush, 5 to 8 feet high. In cold districts it is well to give it shelter, but in the south and west it does not require this. There are male and female forms, the more elegant being the pollen-bearing or male plant."

vulgare, which grows to great size and in the utmost profusion. Among the shrubs that everywhere decorate the expanse of grounds are to be seen thriving specimens of *Euonymus*, *Escallonia*, *Griselinia littoralis*, *Choisya ternata*, *Veronicas*, *Arbutus*, and *Aucubas*, many of which bear berries freely every year. The less hardy shrubs, however, have much to contend with, owing to the frequency and the strength of the prevailing north-westerly gales, which blow in from the Atlantic. On the south front of the mansion are to be seen two fine plants of Banksian Roses, white and yellow, and on the eastern side a very fine plant of *Magnolia grandiflora*.

Proceeding to the outskirts of the lawn, several fine evergreen Oaks (*Quercus Ilex*) rise to view; and upon further exploration, the visitor in another part of the grounds lights upon a disused quarry, approached by a tunnel cut out of the rock, and through which access is afforded to the church and the railway station. The quarry has in one corner a small pond, the surface of which is overspread with

FIG. 80.—PRIDEAUX PLACE.

Prideaux Place.

PRIDEAUX PLACE, the seat of Prideaux Brune, Esq., lies in close contiguity to the Atlantic Ocean, above the little town of Padstow, upon the north coast of Cornwall. The house (fig. 80) itself, built in the Elizabethan style, overlooks the picturesque quay of Padstow, and stands upon a broad terrace, from which there extends a charming view across the deer paddock and sand hills on the other side of the harbour. Beyond these rise the Cornish hills Rough Tor and Brown Willy, while from various parts of the well-kept grounds glimpses of charming pieces of harbour scenery are to be obtained.

The pleasure grounds, about 20 acres in extent, have as one of their most conspicuous features a profusion of spring flowers—viz., Snowdrops, Scillas, *Anemone apennina*, and Daffodils in great variety; but above all *N. telamonius plenus*. The position of these adds immensely to their effect, for they grow out of the Ground Ivy which forms a carpet under the trees, while around Primroses of white, yellow, and various other colours flourish in wild and uncultivated luxuriance. To these features may be added the Hart's-tongue Fern, *Scolopendrium*

Water Lilies (*Nymphaea alba*), and surrounded by *Gunnera manicata* Bamboos, and *Phormiums*. In the formal garden, represented in the illustration upon page 293, very good effects are obtained in summer by Cannas, Begonias, and *Lobelia cardinalis* Queen Victoria, of which there are about 600 grown annually, all doing remarkably well when receiving generous treatment from the watering pot. Specimen Ivy-leaved "Geraniums," and Fuchsias plunged in the turf also add to the general effect. On the left-hand side of this garden and extending much further is a long grass alley, which in former years was used as a bowling green.

The conservatory forms a by no means insignificant feature of the general panorama. Around the pillars of this cluster in graceful convolutions upwards to the roof *Tacsonia Van Volkemi* and *Cobaea scandens variegata*, the whole being thrown upon a background of *Asparagus plumosus* by the wall. During summer Begonias, *Campanula pyramidalis*, Cannas, and *Gloxinias* contribute greatly to enhance the charming aspect of this conservatory. Turning to the kitchen gardens, fruit, and plant houses, which are situated some distance from the house, we find a good collection of *Chrysanthemums*, and plants for decorative purposes and flower cutting, which are diligently requisitioned in the season. Much use is made of *Primula stellata* for

decorative work. Peaches do well upon the south walls, but other aspects do not serve so well owing to their exposure to the high winds, which are a great bane to the gardener, Mr. W. Brown. Tomatoes, however, grow well in the open, and are largely cultivated. A reserve garden serves to furnish Carnations and various sorts of herbaceous flowers for ornamentation of the rooms when occasion requires.—VISITOR.

[For the excellent illustration of the formal garden and the conservatory we are indebted to Messrs. Foster & Pearson, Ltd., Beeston, from whose splendidly produced new catalogue it was taken.]

Subtropical Bedding.

THE great charm of gardening lies in its many phases, which provide such diverse interests to those who have the "gardening instinct." Some enthusiasts delight in growing Cabbages, others are chiefly interested in the production of various kinds of fruits, and all are more or less interested in the flower garden and shrubberies, which lend themselves to such widely different styles of arrangement. Subtropical bedding provides a distinct feature in a flower garden, park, or even in the amateur's limited domain. The original idea in carrying it out was to so arrange plants of bold or graceful foliage as to represent tropical vegetation.

Many of the plants employed for the purpose are natives of tropical countries, and can therefore only be employed in the open air during the hottest part of the year, and during the remainder of the year they take up much valuable space under glass. There are, however, a number of others which may be raised from seed each spring, and if planted out early in June will grow into fine specimens during the summer, and when the autumn frosts despoil them of their beauty may be consigned to the rubbish heap. A few plants used for the subtropical bedding are quite hardy, and may therefore be left in their position permanently. The Pampas Grasses, Bamboos, and Funkias belong to the latter class. I will now deal with a few of the most suitable plants which can be raised from seed, and will refer to their arrangement in subsequent notes.

The Castor Oil Plants are unrivalled for the purpose, as they grow so rapidly and are always admired. The most popular variety is *Ricinus Gibsoni*, which produces dark purple stems and leaves, a colour so effective when seen under the brilliant light of summer time. *Ricinus roseus magnificus* assumes a bushier habit of growth than the former, and the seed vessels being of a beautiful rose-pink colour, form an additional attraction. Among the green-leaved varieties *R. zanzibarensis* stands out as a veritable giant. In habit of growth and leafage it greatly resembles that well-known greenhouse plant *Aralia Sieboldi*, but the leaves of the *Ricinus* are large, often measuring 2 feet across. *R. zanzibarensis maculatus* is also worth growing. The leaves are coppery-bronze when in a young state, afterwards changing to dark green with reddish ribs. The seeds should be sown in well-drained pots, and be covered with an inch of soil. A stove, or a frame placed over a hotbed, are excellent positions in which to raise the plants, but where such convenience is not at command they may be raised in a warm greenhouse. In order to facilitate germination steep the seeds in warm water for a few hours before sowing.

The fine new varieties of Cannas now so popular are as much, if not more, noted for the beauty of their flowers as for the boldness of their leaves. A packet of mixed seeds will often give some variation of sterling merit. The directions given above for raising *Ricinus* are equally suitable for Cannas, but the latter plants will not grow very large during the first season, and should be lifted early in October, stored under a greenhouse stage, and kept dry at the root till the following February. If they are then repotted young growth will be produced. Very little water will be needed till the roots become active, then the supply must be gradually increased. During the summer such plants make fine clumps for the centre of a flower bed or the background of a border. Those who prefer to keep them in pots should give them a light position in the greenhouse, and water occasionally with liquid manure; they will then prove by no means the least attractive inmates of that structure.

The *Dracaena*-leaved Beet (*Beta chilensis*) is quite distinct from the edible kinds, and the broad highly coloured leaves make it worthy of a place in any garden or shrubbery. Sow the seeds in a greenhouse or frame during March, or in the open air at any time throughout April. *Wigandia caracasana* and *W. imperialis* are rapid growing plants, which in one season attain a height of from 4 to 6 feet. If large plants are required, sow the seed at once; if only moderate sized ones, defer the sowing till the end of April.

The striped Japanese Maize (*Zea japonica variegata*) is an exceedingly graceful plant, which the garden artist may turn to

advantage in a variety of ways. A well-grown specimen looks particularly well in the centre of a flower bed, or a larger bed planted with a groundwork of Beet, with Zeas disposed 3 feet apart, and a *Dracaena Veitchi* or *Chamærops humilis* as a central plant forms a very effective combination. After being soaked in water, the seeds should be sown at once. I like to set them in boxes an inch apart, transfer to 3-inch pots when the young plants are 3 inches in height, and pot on when necessary.

Nicotiana affinis, the Sweet-scented Tobacco Plant, which has broad, dark green leaves and tall spikes surmounted by white flowers, is often employed for subtropical bedding. If seeds are sown at once in a warm greenhouse or stove good plants may be grown by June. *Acacia lophantha* and *Grevillea robusta* are greenhouse shrubs which have elegantly formed leaves, and are largely employed for bedding as well as for decorative work in pots. In order to get plants 3 feet in height by June the seed ought to be sown in September. Any old plants now at command if repotted and well attended to will surely prove useful at bedding out time, no matter how large or of what shape they may be. Plants 5 or 6 feet in height are often just the things required to form a background or a prominent object in the angle of a bed or border.

Perilla nankinensis, a dark, almost black, foliaged annual, is very effective when used for massing. It grows very quickly, and attains a height of 2 feet. Seeds should be sown on a hotbed or in a warm greenhouse. *Chamæpeuce diacantha*, a Thistle-like plant, having green leaves marked with silvery lines, is excellent for filling large or small beds. Sow the seeds at once in a warm greenhouse.

The well known Blue Gum Tree (*Eucalyptus globulus*) is quite indispensable for subtropical bedding, as it attains a great height, and in sheltered position in the south of England will withstand the rigours of our winters for years. One-year-old plants should be employed for planting, and often if large specimens are required these can be potted in the autumn and wintered in a greenhouse when grown in positions where it is not safe to leave them in the open air.—H. D.

Melons.

At a recent meeting of the Kingston Gardeners' Society, Mr. Turner of Fulham Palace Gardens gave a practical paper on Melons. The essayist described the methods of culture adopted by the late Mr. Gilbert at Burleigh and by Mr. Woods at Osberton Hall. The best Melons, in his opinion, were grown in low span-roofed houses with a 6 feet wide bed in the centre with a pathway around. The seeds were sown singly in small uncrocked pots, and afterwards transferred to 6-inch pots, using if possible loam from a grazing pasture. A fermenting bed was formed upon which the soil was made very firm and the plants put out on hillocks 3 feet apart on each side of the bed and trained up stakes leaning towards the pathway and the sides of the house. The temperature was kept at about 70°, and air admitted above that figure; no shading was given to the plants.

Frequent top-dressing served the double purpose of giving fresh rooting space and of keeping the roots from going down into the fermenting bed, which is detrimental to the plants. Early flowers were removed until sufficient growth had been made to insure five fruits set at one time. The shoots were stopped at one leaf beyond the fruit. Stimulants were given in the form of guano dissolved in water. Mr. Woods' system was to take up three shoots from each plant, obtaining three to five fruits on a plant; other details were similar to the foregoing.

Mr. Turner then proceeded to point out that Melons could be grown in boxes in any plant stove without the aid of a fermenting bed. Where there is no space for a hotbed, and where for some reason it is difficult to make the ordinary bed of soil, boxes will be found convenient, these being 2 feet long by 18 inches wide, and 10 or 12 inches deep. Boxes were better than pots, but if the latter were used they should be plunged in some material; one fruit on a cordon in a 12-inch pot was about the usual practice. This does not apply to boxes in which the plants may be heavily fruited.

An important cultural point was to avoid heavy syringing, as this was the chief cause of spot and canker, and for the latter there is no known cure, although lime and charcoal rubbed into the affected part will arrest the progress of the disease. The choice of varieties was left to each cultivator.—J. T. BLENCOWE.

VITAL ENERGY.—Live plants are plants with their particles in motion building up the plant's structure. This motion is known as vital energy. Physical energy results in decomposition. The material out of which plant structure is formed is known as protoplasm. The forms of flowers result, says a transatlantic contemporary, from varying degrees and directions of vital energy; but what starts the motion in protoplasm, and so directs the energy that a little cell may develop in one instance to an Oak, or in another to a Buttercup, has not been demonstrated. We speak of vital force, or life energy, as a fact, but no one has yet discovered what starts the movement.

The Hildesheim Rose.—It is reported that Hildesheim's famous thousand-year-old Rose bush, which it had been feared in the last two years was dying, has sent out new shoots and runners from a thick root-stock, and seems now to be safe to last for a good many years to come. The plant did not flower last summer.

The Anemone.—The Anemone, or Windflower, is common enough throughout the Home Counties, more especially on the borders of woods, where it may be found in the middle of March. What are frequently taken for the petals are sepals. As in the case of the Marsh Marigold these are coloured, and the petals are not present. A variety of the Anemone is the Pasqueflower (*A. pulsatilla*). It is of a purple colour, and, unlike the Wood Anemone, secretes honey. It may be found in various parts of Sussex, and notably in the woodlands about Uckfield. The Pasqueflower has a thicker stem, covered with silky hairs. Years ago it was a fashion to stain eggs with the juice of the Pasqueflower—Easter eggs, they were called.—("Echo.")

Influence of Electricity on Germination.—Some remarkable experiments with electricity have just been made. On an egg which was being hatched it was found that an electric current of sufficient strength to kill the fowl did not destroy the vitality of the germ in the egg. But the chicken when hatched was one of abnormal shape and monstrous in appearance. Experiments with seed proved that a seed planted in the ground does not grow as quickly as one rushed in its development by electricity. Two lots of twelve groups, each of 112 seeds, were soaked in water and placed in cylindrical glass vessels open at each end. The receptacles had dipping into them copper discs to which a current was applied. The seeds were kept at a temperature of 50°. The seeds treated electrically grew 30 per cent. quicker than those treated in regular manner.

Long Life of Seeds.—An interesting fact has been observed by Colonel Thompson during the past two years. A little plant called *Pilea microphylla* has constantly come up in the pots in which jadoo fibre has been used, and as this plant is a native of the West Indies and tropical America, it is clear that it comes from the moss, which is obtained solely from Yorkshire, and which is used in the preparation of jadoo, though in this climate the *Pilea* cannot grow in the open air. The surmise of the colonel is that the seed was deposited in the moss ages ago when a tropical climate prevailed here, similar to what it was in the mid-Eocene period. If this conjecture is correct, we have some extraordinary testimony in favour of the great vitality of seeds, far surpassing anything that has been advanced in this connection before.

Galax Leaves.—These leaves, which within a few years have become so popular in floral design work, are gathered in the mountains of North Carolina and Eastern Tennessee. Picking begins early in September, but the leaves cannot be shipped safely by freight until later. The bronze leaves, which are in much greater demand than the green, cannot be got until about the middle of November, when the rich colouring is caused by successive frosts. The pickers put the leaves in bundles and take them to the general merchandise store, where they are received practically as cash at about 25 cents a thousand. The receivers have no regular arrangement for storage of large quantities, and aim to unload the material as fast as received, which they usually do, as the demand about equals the supply. Dealers north place contract orders with them for certain quantities to be delivered at their convenience between specified dates. The leaves are packed dry with a little sphagnum moss among them, which supplies all the moisture they need. They keep better and travel better if frozen; in fact the same conditions that are required for hardy Ferns in storage just suits them, and most of the damage to them comes from the same cause that injures the Ferns—heating in transit. The dealers place them in commercial cold storage houses at about 28° Fahr., and if in good condition when stored thus they will remain so for an indefinite period. Florists after receiving them should, says the "American Florist," aim to keep them constantly in a temperature below freezing until ready to use them.

A Wonderful Tree.—It is said that a great many Burmans are being attracted just now to Amarapura to visit a Banyan tree at that place, which is said to be yielding rather a plentiful supply of water. Incisions are made in the tree, and as the water exudes it is caught up in bottles and other vessels and carried carefully away. The people believe that this water has numerous medicinal properties, and is very efficacious in the cure of almost all diseases flesh is heir to, especially blindness. It is described by one who has drunk it to be very cold and not unpleasant to the taste.

Frost Flowers.—The phenomenon called "Frost Flowers" was discussed before the Biological Society in Washington, U.S.A., recently, by Dr. L. H. Dewey. The so-called flowers are composed of ice, which forms on frosty mornings in autumn and early winter on certain plants. The peculiar thing to be explained is that frost flowers do not form on all plants, but only on about twenty-six species, as far as is yet known. Among these are Frostweed, Dittany, Marsh Fleabanes and cultivated Heliotrope. The phenomenon is apparently due to capillary movement of water in the plant, but a wholly satisfactory explanation is lacking.

Orchards and Fowls.—At Ruxley Lodge, Esher, are several considerable orchards, old and new. When walking through one of the older ones, perhaps a couple of acres in area, a few days since I remarked to Mr. Miller, the gardener, that the fowls who had the run of the orchard seemed to scratch freely in the surface dressing put down. He remarked, "Yes; I have let the poultry run here for two years, and for that time have never been troubled by insect pests." Now it is his practice to accumulate an immense quantity of leaves from all descriptions of trees, as most gardeners do in such places, and to utilise them for creating some warmth for frames in the spring. In the early winter, ere the new leaves are collected, this leaf matter, for it is not yet soil, is removed into the orchard, where some is cast about under the trees, and thus constitutes excellent dressing, whilst the remainder is put into a large heap to more completely decay. Naturally such material is eminently calculated to contain insect life, but if so, at least it is soon devoured by the poultry, for they search it and scratch it so continuously that poor indeed is the chance for egg, grub, maggot or larva to escape. The dressing feeds the soil, which is of deep sand, remarkably well, and retains moisture much longer than it would were it not so mulched. There are huge crops of Apples so obtained at Ruxley Lodge, although many of the varieties there are those that no one would plant now. But not far off on lower ground there is a fine orchard on clay planted a few years ago, where good varieties of both Apples and Pears do remarkably well, and doubtless will for many years. Close by, within the ancient enclosed abbey garden, is a Blenheim Pippin espalier, evidently 150 years old, that still carries fine fruit.—A. D.

Late-keeping Apples.—At the last meeting at the Drill Hall, amongst other Apples sent, for so late in the winter, in capital preservation by Mr. Parker from Goodwood, were really good and fresh Sturmer Pippins. I have found this variety to keep well from retentive soil, but I hold with it, as with so many other Apples, that much of the keeping properties depends on the period at which fruits are gathered. Sturmer Pippin wants a long season to finish it well, and my judgment is in favour of growing it as espaliers, because not only can the trees in such case be netted over if desired, but the fruits suffer no harm from rough winds in the autumn. The Sturmers that came from Goodwood, whilst not only plump and fresh, had undoubtedly the best flavour to my taste, certainly King of Tompkin's County obtained an award of merit for its soft pleasant eating flesh just then, but it had no special flavour. Such an award was given, doubtless, because the fruits had kept so well. But I emphasise in the matter of getting both Apples and Pears to keep well, Mr. Woodward's treatment of his trees at Barham Court, where he specially waters liberally all that are to carry crops late into the autumn. Such soaking helps materially to fill the fruits with sap and the trees to retain the fruits so much longer. To these liberal waterings are added mulches of manure also. Such soakings are exceptionally needed when we have very dry autumns, for we must not forget that whilst moderate rain may penetrate a few inches into the soil and greatly assist crops, only thorough soakings get down and assist tree roots. Cox's Orange Pippin, which when well done keeps to the end of February, as mentioned by "E." is yet naturally an earlier ripener than is Sturmer Pippin. Mr. J. Crook gets fine long-keeping Cox's from standard trees grown in his orchard beside the river Exe at Forde Abbey, Chard.—A. KINGSTON.

Rose Show Fixtures in 1900.

- June 27th (Wednesday).—Salisbury (N.R.S.) and Richmond (Surrey).*
- „ 28th (Thursday).—Canterbury.
- „ 30th (Saturday).—Windsor.
- July 3rd (Tuesday).—Westminster (R.H.S.), Gloucester, Harrow and Sutton.
- „ 4th (Wednesday).—Croydon, Hereford and Reigate.
- „ 5th (Thursday).—Bath and Norwich.
- „ 7th (Saturday).—Crystal Palace (N.R.S.).
- „ 10th (Tuesday).—Wolverhampton.†
- „ 12th (Thursday).—Brentwood, Eltham and Salterhebble.
- „ 14th (Saturday).—New Brighton.
- „ 18th (Wednesday).—Cardiff.*
- „ 19th (Thursday).—Birmingham (N.R.S.) and Helensburgh.
- „ 24th (Tuesday).—Tibshelf.

* Shows lasting two days. † Show lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear in an early issue.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Roses and the Frost.

THE winter we have just passed has been a pretty severe one, and on several occasions here (Surrey) the temperature was low enough to test the hardiness of Roses. Hybrid Perpetuals without any protection have passed unharmed, as they usually do; but it is the Teas which cause one to be somewhat uneasy during severe weather, and which rarely get through our usual winters without harm to some sorts being done.

The only variety plants of which are completely killed is Comtesse de Nadaillac, a beautiful Rose truly, but one that is unsatisfactory in growth with most people. Bridesmaid, another fine Tea Rose, has suffered considerably, as well as others of the family of sports, or rather, the type Catherine Mermet, the above offspring and The Bride. These are a bit delicate in the open, but by protecting them we may generally save the lower portions of growth, which is sufficient to give new life. Cleopatra, Princess Beatrice, La Boule d'Or, Luciole, Ma Capucine, Niphetos, Princess of Wales, Souvenir d'Elise Vardon, and even Madame de Watteville and Madame Cusin are tender Roses which, except for purposes of showing, are hardly worth attempting in the garden. As exhibition flowers they are, with one or two exceptions, fine; and one is inclined to risk their faults of tenderness and want of vigour, even in summer time, with the hope of obtaining a good bloom now and then, rather than discard them altogether.

That choice Tea Maman Cochet is really a splendid production. Not only are the blooms lovely in themselves, but the plant is so free to grow and hardy. This type of Tea Rose is the one to encourage; there are no disappointments in store for those who cultivate such. We are not overdone in good hardy, free-growing Tea Roses that give finely developed blooms as well. Anna Olivier is one; Ernest Metz seems only fairly hardy; Hon. Edith Gifford will withstand a severe winter; Innocente Pirola is but fairly robust; and Francisca Kruger and Madame Lambard, although hardy and good in every respect save one—that is, the blooms are not up to exhibition form—are for that reason not popular among the choicest. In this category are Souvenir de S. A. Prince and Souvenir d'un Ami, otherwise they are excellent for general culture.

The newer class of Hybrid Tea Roses appear to be hardier generally, but that best of all among them, Mrs. W. J. Grant, is none too hardy with us. Several plants have failed. Kaiserin Augusta Victoria, a lovely creamy white, is hardy, and Caroline Testout will grow well anywhere. Marquise Litta passed the winter well, and is deserving of the most extended culture. Grace Darling, not a reliable show Rose, is one of this class, really beautiful as a garden variety. Lady Mary Fitzwilliam and White Lady seem hardy, but we cannot get enough growth into the trees to make them satisfactory varieties to plant. Viscountess Folkestone is excellent; there are, indeed, few better garden Roses, and sometimes one may cut from it a choice show bloom. It is hardy and very free.

The Roses that suffered to any extent were the newly planted ones. These are on standard stems, but were protected with hay at the junction of stock and scion. Probably it is only the tenderer varieties of Tea Roses that need any protection, at least in a somewhat favoured county. In the nurseries of the neighbourhood hundreds of thousands of Roses are cultivated without being in any way protected. Still we do not find, even among this large number, the very tender sorts named grown in quantity. They are left to those, like ourselves, whose desire is to get examples like those we meet with and admire at the Crystal Palace and other shows.—H. S.

Curing Foliferous Vines.

THERE are several things that may have a tendency to encourage Vines in other structures as well as greenhouses to produce foliage at the expense of fruit. The first essentials to strive for in commencing to cure Vines of this fault are new growths, allowing these to extend in full exposure to light, and pruning the well-ripened stronger wood to plump buds. An average heat of 55° is too high for a greenhouse Vine at this time of year; it implies forcing, or a temperature in which a Vine cannot rest.

During winter, or from November to March inclusive, the temperature of a greenhouse with a Vine in it should not exceed by artificial means 40° to 45° at night, and the latter in the daytime. In mild periods it will range rather higher, but this will do no harm provided air is given at 50°, and the temperature is not allowed to rise much higher without full ventilation, closing the house at 50°. All the heat over 45° should be due to mild weather or sun heat; thus the Vine will have rest from the fall of its leaves to starting again naturally in the spring. This, under the conditions named, will be early in April; and after this the temperature must be kept from falling much below 50° at night when the Vine comes into leaf, a little ventilation being given at this stage and freely at 65°, which will be good for both Vine and plants. The heat will rise much higher from sun influence, and there is no need to husband it beyond closing, or nearly so, at 65°. The Vine will make rapid progress during the latter part of April and during May, after which fire heat may be dispensed with unless unusually cold, but only to prevent the temperature falling below 50° at night. A little warmth in the hot-water pipes when the Grapes are ripening will be of service.

Old Vines are rather prone to become weak in the wood, especially on the spur system, and the "cure" in such cases is to encourage new canes from the base and cut away the old in their favour. Supposing the Vine is trained along the eave of the house and the rods are taken from this part up the roof and have spurs along them at 15 to 18 inches apart, we should select a promising growth near the base of each rod and train it up the roof. When this has been done gradually cut away the old cane from below upwards, so as to give each new cane the full benefit of the light, pinching the laterals at the first joint, and the sub-laterals to every leaf as made.

When the cane has grown 3 feet, stop it a joint above that length and take the lateral from the uppermost break forward as leader, and when it has grown another 3 feet repeat this procedure, and stop this when 1 foot from the top of house, all the laterals and sub-laterals being pinched to one leaf as made. The canes thus made will be strong, have firm wood and plump buds, and when the leaves have fallen they may be shortened to a promising bud about 2 feet 6 inches from the base, cutting the lateral close to the cane. In the following spring take a shoot from the uppermost bud forward as leader, subjecting it to the same treatment as in the preceding year, and from the other growths select four, two on each side of the rod, about 15 inches apart, rubbing off the rest. Stop these at two joints beyond the shoot for fruit when the leaf at the joint is the size of a penny, and stop the laterals and sub-laterals to one joint as made. It is not advisable to crop the leader until another year.

In the winter prune the leader to about 2 feet 6 inches, and the side shoots to two buds. In the third year take a cane to within 1 foot of the top of the house before stopping; take also four shoots from the one-year-old part, and of the shoots springing from the growths spurred in to two buds select the most promising one on each and rub the others off. The cane at the winter pruning should be shortened to about 2 feet 6 inches from the top of the house, and the side shoots and spur growths to two buds each, and the following year the Vine will be in full bearing, and will continue to carry fruit for some years to come.

It would also be found advantageous to apply a half-inch dressing of air-slaked lime, pointing in with fork as deeply as the roots allow. The border may then be top-dressed with a mixture of dissolved bones three parts, sulphate of potash two parts, and sulphate of magnesia one part, mixed, using 4 ozs. per square yard, and scratching in lightly with a fork. If the soil be light it would be a further advantage to mulch the border with about an inch thickness of horse droppings, supplying liquid manure occasionally in dry weather.—G. A.

Brighton Show.

April 3rd and 4th.

THE ninth annual spring show of the Brighton and Sussex Horticultural Society was held in the Pavilion, and proved worthy of the best traditions of the Society. Both halls were well filled. The groups of plants and tables of Orchids were the chief features. The competition in the majority of the classes was below the average.

There were two entries in the class for a group of flowering and foliage plants, to occupy a space 13 feet by 7 feet. Mr. Geo. Miles, Victoria Nursery, Brighton, was placed first with an effective arrangement of spring flowering plants, chiefly composed of Azaleas, Clivias, Cyclamens, Ericas, Daffodils, Tulips, and Primroses. Foliage plants were agreeably dispersed throughout, the small Ferns, Asparagus, and Aralias being conspicuous. Mr. J. Hill, gardener to W. Wallis, Esq., Springfield, Withdean, was second with a good informal arrangement of taller plants than those in the first prize group.

Two beautiful tables of Orchids were arranged with Ferns, the first prize falling to Mr. J. Harper, gardener to E. A. Tucker, Esq., Vernon Lodge, Preston, who staged a gay table, on which the most

class for twelve pots of Polyanthus Narcissi, and he well merited the first prize which was awarded. The plants were just in the acme of condition. The same exhibitor was also an isolated first for twelve pots of Narcissi, staging some good Horsefieldi, Emperor, and Princeps.

For twelve pots of Cyclamens, Mr. C. Murrell, gardener to Mrs. Jenkins, Franklands, Burgess Hill, was well to the fore with a good variety of plants, followed by Mr. Geo. Miles. Azalea indica was represented by two exhibitors. Mr. F. Collis, gardener to Mrs. Hughes, Preston Park Avenue, proved the victor with well-flowered plants of medium size, while Mr. J. Hill was second with plants that were far from ready. The Deutzias were only moderate in quality. Mr. J. Hill was placed first, followed by Mr. H. Head, Hove. There was a better competition for six pots of Dielytras, Mr. H. Head staging six beautiful plants, while Mr. W. E. Anderson was second with larger plants, but they were not ready, and Mr. Geo. Miles third.

The class for six pots of Richardias was excellent, and the competition good, Mr. J. Harper securing premier honours with plants carrying from six to eight splendid spathes. Mr. W. E. Anderson was second with larger plants, carrying more flowers, but they lacked the quality so prominent in the first prize entry; Mr. G. Miles was third. For twelve Genistas Mr. H. Head was placed first for large plants, beautifully grown and a mass of yellow flowers. Messrs.

FIG. 81.—CONSERVATORY AT PRIDEAUX PLACE. (See page 289)

prominent plants were some good *Odontoglossum crispum*, *Oncidiums* in variety, *Dendrobiums Ainsworthi*, *Wardianum*, and *nobile*, with a few choice *Cattleyas*; and Mr. H. Garnett, gardener to R. G. Fletcher, Esq., Mount Harry, Preston, was second, staging some choice *Odontoglossums*, *Cattleyas*, and *Dendrobiums*, the groundwork of Ferns effectually hiding the pots.

The competition for twelve Hyacinths brought out a good competition, but there was nothing startling in the quality. Mr. W. E. Anderson, gardener to B. Parish, Esq., Preston Park Avenue, Brighton, was first with good spikes of *Norma*, *King of Blues*, *Gigantea*, and *Charles Dickens*. Mr. G. F. Bunney, Lewes Road, Brighton, was a capital second, and Mr. J. Harper third with an even display.

Twelve pots of Tulips only secured two entries, but they were both good, Mr. W. E. Anderson having good specimens of *Keizers Kroon*, *Cottage Maid*, *Vermilion Brilliant*, and *L'Immaculé*, and Mr. J. Harper was second with a bright, fresh collection, though hardly so developed as the other exhibit.

Strange to say the prizes for six Primulas were all awarded to white-flowered plants. Mr. G. Hart, gardener to H. Head, Esq., Shoreham, was placed first with good fresh plants; Mr. W. E. Anderson was second; and Mr. J. Hill third. The class for twelve pots of Lily of the Valley made an imposing display. Mr. A. E. Golding, gardener to H. G. Vowles, Esq., Dyke Road, was first with some well-developed plants, carrying plenty of spikes. Messrs. W. Miles & Co., Church Road, Hove, was second; and The Brighton Florists' Stores third. Mr. J. Harper was the only exhibitor in the

W. Miles & Co. were a good second, and the Brighton Florists' Stores third. Mr. J. Harper had the best six pots of *Lilium Harrisii*, followed by Mr. W. E. Anderson, while Messrs. W. Miles & Co. brought up the rear.

In the class for twelve bunches of Narcissi Mr. J. Harper was first with a bright fresh collection, which included *Henry Irving*, *Empress*, *Emperor*, *Golden Spur*, and *Sir Watkin*. Mr. M. Tourle, gardener to F. Barchard, Esq., Uckfield, was second with excellent bunches of *Victoria*, *Empress*, *M. J. Berkeley*, and *P. R. Barr*. *Mignonette* was well staged, Mr. J. Mills, Kingston-by-Sea, being first with six grand pots. The Brighton Florists' Supply came second, and Mr. G. Hart was third, both with weaker exhibits.

There were two competitors in the class for ten Orchids, and Mr. H. Garrett won easily with a grand specimen of *Cymbidium Lowianum*, a well flowered plant of *Dendrobium Dalhousianum*, *Cypripedium levigatum*, *insigne*, and *Rothschildianum*, also *Cattleyas Trianae*, *T. Fletcherianum* and *Mendeli*, with a beautiful plant of *Odontoglossum Andersonianum*. Mr. J. Harper was second with much smaller specimens. The *Cinerarias* were bright and contrasted well with the golden *Genistas*. Mr. L. E. Cooko, gardener to Miss Smith, Withdean, was first with a pleasing variety. Mr. G. Hart was second with dwarfier plants that will improve. The colours were excellent.

Messrs. W. Balchin & Sons, Hove and Brighton, arranged an artistic group of flowering plants and Ferns, with a few specimen Palms. The large blocks of *Dendrobium nobile*, *Anthuriums*, *Azaleas*, *Hydrangeas*, and *Cyclamens* were excellent, and the edging of *Isolepis* and *Asparagus Sprengeri* formed a pleasing front.

The Young Gardeners' Domain.

Bouvardias.

BOUVARDIAS are very useful for supplying large quantities of cut flowers during winter, and the plants look very effective when tastefully arranged in the flowering house or the conservatory. In February or March the old plants should be pruned, and then be placed in a warm moist temperature, where they will soon produce a plentiful supply of young shoots; the tops of these should be taken off when several inches long, and rooted in pots of sandy soil in a propagating case. Or the roots of some old plants may be cut into lengths and placed in pans of sandy soil; these will soon make fine little plants if the pans are plunged in a bed where there is a moist bottom heat, and are covered with squares of glass.

When the young plants are large enough they should be placed into 3-inch pots, using a mixture of peat, loam, leaf soil, and sand in equal parts; the pots should be placed in a heated pit or frame where they will be near the glass, the temperature of the pit being about 60° or 65°, and gradually reducing it as the plants gain strength. They must be carefully watered, and should never be allowed to become dry; nor should they be kept constantly saturated with water, or they will soon become unhealthy. The points of the shoots should be pinched out to insure a bushy habit, and when the pots are full of roots put them in 4½-inch or 5-inch pots, using a similar compost as before, but with rather more loam. The plants ought to be neatly staked, and be placed in a close frame for a few days. When established in these pots the frame should be freely ventilated, gradually hardening the plants until in June they can be planted out in the open, fully exposed to the sun, in good rich soil, where they must be well looked after, watering them at the roots and frequently syringing them on bright days; the points of the shoots should be pinched out about twice during the summer.

Early in September the plants must be carefully lifted and placed in 6 or 7-inch pots. They should be stood in a frame and kept close and shaded for a few days, frequently syringing them until they get over the shift they have undergone. They should be placed in a greenhouse where a temperature of 55° is maintained when required to flower, and be fed with weak liquid manure twice a week. Some of the best varieties of Bouvardias are Alfred Neuner, candidissima, Hogarth, Humboldtii corymbiflora, President Cleveland, President Garfield, The Bride, Thomas Meehan, Triomphe de Nancy, Victor Lemoine, Vreelandi, and Vulcan.—F. W. P.

Cyclamen Culture.

FEW flowering plants are more useful during the winter months than Cyclamen persicum, as they will throw up such an abundance of flowers over a long period. The seeds should be sown thinly in clean, well-drained, shallow pans, early in August in a compost consisting of fine loam, leaf mould, and sand. Place the receptacles in a shallow frame which has a temperature of 60°, and cover them with a pane of glass and a sheet of paper, as this will favour rapid germination. Keep the soil moist, but on no account have it wet. As the seedlings appear above the surface remove the paper and glass, and place the pans as near the roof-glass as possible, but they will require a light shading when the sun is very bright. When the seedlings are sufficiently strong remove them to a house which has a temperature from 55° to 60°, standing the pans on damp cocoa-nut fibre refuse, and again as near the glass as possible, otherwise they will become drawn; give them a light syringing occasionally on bright days.

When the young plants are large enough to handle they will require potting, as if allowed to remain in the seed pans for a long period they will be weakened. Thumb pots are a suitable size for this work, having them well cleansed and drained, and using a compost similar to that for the seed pans, with a little less sand, and affording the same temperature. Give a thorough watering after potting, and again when required. Protect the young plants from the bright sun, but do not apply the shading too heavily. Keep them close for a time until root action commences, and never allow any cold draughts to enter.

After the plants have made a fair amount of roots they will require another shift, and well cleansed and drained 3½-inch pots will be found suitable. Use a compost of good fibrous loam, leaf mould, and sand, a little artificial manure and charcoal, but be sparing with the manure. Do not pot too deeply, but keep the corms well above the soil, otherwise they are liable to decay. Have the plants as near the glass as possible, which will insure sturdiness in growth. Syringe the plants once or twice daily when the weather permits, as this will keep all pests in check. The plants will require another shift when they are well furnished with roots, this time into 6-inch pots, using a similar compost to that for the last potting, but having a little more loam. Keep the house close for a few days, and when root action has well commenced admit air on all favourable occasions, gradually increasing it, as this will cause the plants to grow harder and prepare them for standing in cold frames.

At the end of May or the beginning of June the pots may be plunged in coal ashes in cold frames, and not having them too closely together, so that the air can pass freely between the plants. Admit abundance

of air on all favourable occasions, but during sunny weather the lights should be put on and tilted front and back, and shading placed over them to protect from the sun. The watering must always be carefully done; they will require little manure at present, but an occasional application will keep them a good colour. The syringing must not be neglected, doing this twice daily. Examine the plants occasionally, and remove all decayed leaves and flower buds as they appear.

From about the middle of August discontinue syringing and shading, unless it is exceptionally hot. Early in October the plants should be taken in the house where they are to bloom, but prior to this all preparations should be made, such as having the house thoroughly cleansed. When the time has arrived for this have the pot well cleansed, so as to give a neat appearance when staged, and do not place them too closely together. A suitable temperature is about 55° at night, but during severe weather a few degrees less will prove better for them. Admit plenty of air when the weather is favourable, thus keeping the plants sturdier and healthier. Any time on perceiving green fly fumigate with XL-All vaporiser, which will promptly destroy the pest.—P. R.

Fruit Forcing.

Cherry House.—Trees heavily laden with fruit require more nutrient than those with few fruits, but regard must be had to the vigour of the trees as well as to their crops, applying liquid manure to weakly trees carrying heavy crops, and water only to those of full habit with relatively moderate burdens of fruit. A good soaking of these elements most suited to the trees should be given, and as often as required, to maintain the soil in a thoroughly moist state, but not to induce a sodden and sour condition. Attend to ventilation and temperature, admitting air from 50°, and liberally at 65°. Syringe the trees twice a day, and keep the surface of the border damped. When the shoots have made four or five joints they should have the points taken out, so as to form spurs; but those for furnishing the trees ought to be tied in position early, and be carefully trained in their full length. Aphides must be kept under by repeated fumigation, as if they obtain a hold they are not only difficult to exterminate, but spoil the appearance of the fruit.

Pines.—*Suckers or Plants Started in March.*—When the pots of these are full of roots, but before the plants are root-bonnd, shift them into 10, 11, or 12-inch pots, watering them a day or two previously, so as to have the soil moderately moist when they are potted. Examine the beds, replenishing them if need be by the addition of fresh tan, mixing it with the old to a depth that will afford the required temperature, 95° at the base of the pots until the roots reach the sides, when 90° is more suitable. Keep the air about such plants well charged with moisture, employing no more fire heat than is absolutely necessary to maintain a temperature of 70° to 75° on mild nights. Ventilate slightly at 80°, liberally at 90°, closing with sun heat at 85°, at which time syringe the plants. Examine the plants twice a week, and water those that require it.

Plants Started into Fruit Early in the Year.—These are fast approaching the flowering period, and will be benefited by an occasional sprinkling at the time the house is closed; but when in flower they must not be so treated. The foliage being as yet tender, it will be desirable, in the case of houses with large panes of glass, to afford a slight shading for an hour or two in the hottest part of the day for a few weeks until the leaves become inured to the sun's influence. When the flowering is over the fruit will advance rapidly if the roots are in good condition, and plentiful supplies of liquid manure will be requisite. Attend to ventilation early in the morning, commencing when the temperature is at 80°, and closing at 85° with sun heat. Keep the atmosphere moist when the house is closed, and the bottom heat at 80° to 90°, night temperature 70°, 75° by day artificially. As the suckers appear remove all but one to each plant.

Vines.—*For Early Work.*—Vines in pots afford creditable crops of early Grapes. The Vines should now be in the pots they are required to fruit in, and have the growths trained as near to the glass as possible without touching, so as to secure thoroughly ripened wood. Stop the laterals at the first leaf, and the sub-laterals at one joint, and to every subsequent joint as made. Under this treatment the growths will be sturdy, food largely stored in the canes, also in the well-developed buds, and the wood ripen early and thoroughly.

Grapes Ripening.—Vines in pots have the Grapes advanced in ripening, and require very moderate supplies of water at the roots. To insure a full swelling on planted out Vines inside borders must not lack moisture, but an excessive supply may conduce to shanking and bad finish. A full crop of Grapes is a great strain on the energies of the Vine, especially early forced, and through it perfection in colour is not

always attainable. Much may, however, be done by a liberal and constant supply of warm rather dry air, combined with a rather low night temperature of 60° to 65°, but that in the daytime must be well maintained at 70° to 75° from fire heat, and 80° to 85° with sun heat. Red spider usually makes its appearance on early forced Vines about the time of the Grapes commencing colouring, and the small colonies on the under side of the leaves must be removed with a sponge moistened with a solution of soft soap, 2 ozs. to a gallon of water. As a preventive measure the hot-water pipes may be coated with a mixture of sulphur and skim milk. Care, however, must be taken not to overdo it, or the fumes will act injuriously on the skin of the berries and spoil their appearance. The sulphur vapour is more injurious to the skin of white than black Grapes, Frontignans and Muscat of Alexandria suffering most.

Succession Houses.—Stop and regulate laterals so as to secure an even spread of foliage without crowding. Where there is not room for extension, it is unwise to allow the growths to extend considerably, so as to necessitate a large reduction of foliage at one time, as this results in a check, which often induces shanking at a later period. Attend to thinning the bunches and berries, under rather than over-cropping the Vines. Make sure that the borders have a due but not an excess of water. Vines swelling their fruit should have a moist atmosphere, securing this by damping the paths two or three times a day, and if liquid manure be used at the latest sprinkling it will improve the Vines and act as a check to red spider. Stable and cowhouse drainings diluted down to the colour of mild ale, or an ounce of guano to a gallon of water, is sufficiently strong for damping down with, not using more than a 4 gallon canful to 30½ square yards.

Late Vines.—Disbud and tie out as the growths require it. Close the house early in the afternoon with sun heat, and ample atmospheric moisture secured by damping the paths and borders. Vines that were started in March are making rapid progress, and must receive every encouragement, but avoid hurrying their growth by a close atmosphere and high night temperature, ventilating judiciously early in the day so as to secure sturdy growth, short jointed wood, and well formed, thick, leathery leaves.

Young Vines.—Last year's planted canes will now be breaking naturally, and when the growths are fairly on the move a little fire heat will prove beneficial, especially on cold days. When the growths are about half an inch long, gradually remove those not required, leaving the shoots for bearing or forming the side growths or spurs not closer than 15 to 18 inches on each side of the cane. If fruit is taken crop lightly. One or at most two bunches is as much as Vines in the first year of fruiting should be allowed to bear, but supernumeraries may be weighted with as much fruit as there is a prospect of their bringing to maturity.

The Kitchen Garden.

Asparagus.—Cold frosty weather greatly checked early growth, especially where no protection was given. The tender young shoots are often spoilt by frost, when this might have been prevented by hovering strawy litter over the beds every evening, and removing it in the morning of sunny days. If leaf soil is banked up round plants grown thinly on the level, this both protects and blanches the shoots, adding apparently to their value. Enough salt to quite whiten the surface of the beds acts as a good manure, and further serves to keep down slugs and weeds. In the case of heavy clayey soils it is well to omit this dressing of salt.

Planting and Sowing Asparagus.—Planting is best done in warm, dull weather. After the top growth has commenced is a good time to transplant Asparagus, and two-year-old plants receive less check in removal than do those older. Beds ought to be prepared in advance of the planting time. Those 5 feet wide are most often met with. In these the plants are disposed in three rows, the outside ones being 1 foot from the edges. A distance of 18 inches apart is not much to allow between the plants. Prepare a small mound for each plant, distributing the roots evenly round this, and covering the crowns with fully 3 inches of fine well prepared soil. On the level the plants may be put out 2 feet or more apart each way. Seeds may be sown immediately that the ground is in a fit state.

Seakale.—Late unforced but well blanched Seakale will be in great demand this spring owing to the scarcity of green vegetables. In many cases the old stems have been allowed to grow so tall that covering sufficiently with ashes, leaf mould, or ordinary soil is somewhat difficult. This difficulty may be obviated another season by cutting down the long stems close to the ground, doing this after they have had their blanched or unblanched top once or twice cut off for use. Seeds may be sown thinly in drills 1 foot apart, and the seedlings, if the soil is moderately rich and free working, will attain a fairly large size by the autumn. The better method of propagation, however, is by root cuttings, these being either started in boxes of sand or soil, and a gentle moist heat, or the cuttings may be inserted where the plants are to grow.

Rhubarb.—If litter is placed over the crowns to protect the advancing stalks from cold winds and frost, it should be hovered up occasionally, or it may do more harm than good. Plants that have been covered and forced ought not to be carelessly exposed to all weathers immediately after pulling has ceased. After removing the manure hover strawy litter over the plants for a time. Forced roots ought to

be given one season's rest. For ordinary purposes it is well to form fresh plantations occasionally. Just when the crowns are moving is the best time to do this. The old clumps may be divided freely, leaving one or more crowns to each division.

Herbs.—These ought not to be neglected. Those of a perennial nature pay well for lifting, dividing, and replanting in good fresh soil, while the annuals have also to be thought of at the present time. Sow seeds in boxes of Sweet Basil, Bush Basil, and Sweet Knotted Marjoram, and place in gentle heat to germinate, planting out the seedlings when large enough. Sow on a prepared border Borage thinly in drills 2 feet apart, and Fennel the same distance. Pot Marigold and pot Marjoram in drills 12 inches apart. Sow Chervil in drills 9 inches asunder, and Parsley in drills 12 inches apart. Early raised plants of the latter transplant readily. Divide and replant Mint, and also Chives.

THE BEE-KEEPER.

Seasonable Notes.

THE first three months of the year have not been favourable to bee-keepers. After the unsettled weather experienced during the early days of the new year we looked forward to bright sunny days such as were pretty frequent in March, 1899. But again disappointment has to be chronicled, as with little exception it has been dull and cold; the wind was in a cold quarter all this time. What has been the effect? On those days when the bees were tempted to leave their hive they rapidly became chilled, and many were lost. The prevalence of a low temperature at this season is most trying to the bees; as they are unable to fly far from home they often alight on the cold soil, which is fatal to them.

It is of the utmost importance that the bees should now receive the necessary attention to keep them in good condition; warmth is absolutely essential, and feeding must not be neglected. The treatment the bees receive during the next two months will make all the difference between success and failure. Stores have disappeared at a rapid rate. It is surprising how long a cluster of bees will keep alive when in a state of stupor at this season, although only a few ounces of stores remained in the hive. Whilst examining several colonies in frame hives recently one was found completely without stores. The bees appeared to be almost lifeless, many of them falling on to the floor board. We at once covered them up and warmed a couple of bricks, which were placed on the top of the frames, the quilt and a couple of pieces of carpet being allowed to remain underneath. The bricks were covered up so as to retain the heat as long as possible. Some warm syrup was in the meantime prepared in case it should be required. In half an hour the stock was again examined, when at least two-thirds of the bees were found to be alive. A bottle feeder filled with warm syrup was placed over the cluster and some more warm bricks. These had the effect of keeping up the temperature of the hive, enabling the bees to take the syrup freely.

Feeding Bees.

It is better to err on the side of safety by feeding the bees when they have ample stores in their hive, than to neglect those that are probably on the point of starvation and not feed at all. Feed all the stocks at this season, as the weather has been so trying throughout the early spring, rather than overhaul the frames and lower the temperature of the hive. Directly the weather becomes more genial all this can be counteracted by uncapping the stores of those which have it in this condition. This uncapping of stores has the same effect on the bees as feeding, as they at once commence to empty the cells and place the contents in various parts of the hive where it may be required. It is advisable to uncap about two square inches of comb every third or fourth day. If artificial feeding is necessary warm syrup may be used, as a favourable change in the weather may now be expected at any time.

Another great advantage is derived by uncapping the sealed stores in a hive, a much greater space being provided for the queen to deposit her eggs. This fact is too often not taken into consideration. We have found stocks on which sections were worked the previous year to have several combs of sealed stores at this season. If steps were not taken to remove some of the frames and uncap the others, the bees would probably swarm before the hive was half full of bees, owing to the combs being clogged with honey. We have often experienced this in our own apiary. Stocks that have been doubled and the honey extracted from the top storey are usually found to require much more feeding than those used for securing a crop of comb honey; in fact it is rarely the latter require any feeding at all. This fact should be taken into consideration when arranging for run or comb honey. A greater weight of honey can usually be obtained by extracting, which in many districts finds a readier market than honey in the comb.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Vine in a Greenhouse (E. H.).—You will find your question answered in the form of an article on page 292. If the instructions given therein are followed the results are practically sure to be entirely satisfactory.

Grafting Paradise Stocks (G. C. F.).—The stocks having been planted at the beginning of the year will not start into growth so early as those which have not been moved, and should not be worked until the sap flows more freely—say at the end of this month or early in April. It may be done when the buds commence breaking, taking care to keep the scions quite dormant, as they will by inserting in damp soil or sand on the north side of a wall or fence. Whip grafting is the best method for small stocks, and it can be practised on much smaller stocks than crown grafting. The grafts should be inserted about 6 inches from the soil, as it is necessary the trees have a clear stem above the ground to derive the benefit of the stock. Cover the joint with grafting wax after securing the scion with bast.

Vines Unsatisfactory (M. A.).—The specimens of leaves and bunches are very unsatisfactory, the former being small and thin in texture, though quite clean and healthy, and the latter are stunted and in some cases shrivelled. Of Alicante and Gros Colman you may secure some fruit this season, but of Muscat of Alexandria and Madresfield Court the prospects are extremely uncertain. The cause is usually an unsatisfactory condition at the roots, not in your case at present, as the borders both inside and outside have been renovated, but to the bad state in the previous year. The renewal of the inside border two years ago would only affect the roots there, which were, no doubt, as commonly happens, few, the main portion of them being in the outside border. As the roots have not, as we take it, been active in the new inside border, the supplies of nourishment have been mainly furnished by the outside one, which, in an unsatisfactory state, has led up to the present condition of the Vines. Now that you have renewed the outside, we consider you may look forward to next year with confidence, although we do not approve of adding so much freshly slaked lime as half a barrowload to ten barrowloads of loam, and using the mixture at once. Had the lime been air-slaked the case would probably been different, and this is the only thing in which you have acted, if at all, wrongly. The other ingredients are all good. We should maintain a rather high and somewhat dry, but not arid, atmosphere for a time, and thus strive to draw out the bunches, say a night temperature of 60° to 65°, and 70° to 75° by day, ventilating moderately from the latter figure, and running up to 85° or 90° from sun heat. Encourage the extension of the shoots, these being allowed to extend beyond the bunches after the first stopping of the bearing growths at two or three joints beyond the show for fruit as space admits, but pinching those below the bunches to one joint, and the sub-laterals also to one leaf as made. In no case, however, allow growths to be made that cannot have full exposure to light, and not allowing the laterals to encroach on the free exposure of the principal leaves. With these matters duly attended to, and not making the borders too wet at any time, especially after the growth is properly developed, well-ripened wood may be looked for, and with it, and not too close pruning, a satisfactory condition of the Vines and Grapes another year.

Hens Eating Lucerne (Heathfield).—Lucerne is not in any way bad for fowls, though when the hens have been penned for a considerable time and fed on cereals—meal, wheat, barley, and maize—exclusively, they naturally are extremely eager for green food. In such case the fowls may at first eat more than is apparently good for them, as green food in excess induces looseness, but only of a temporary character, for the fowls soon return to a judicious proportion of the greenstuff, having overcome the craving for cooling food promoted by the heating properties of the hard food—meal and grain.

Cypripedium bellatulum (J. C. S.).—It is by no means certain that this handsome Orchid would flourish in an ordinary greenhouse. The atmospheric conditions of such a structure are usually very different from those that prevail in cool Orchid houses. Then it must be borne in mind that Mr. W. H. Young, who was referred to on page 261 as growing this *Cypripedium* in a cool structure, is one of the most expert Orchid cultivators we have, and would therefore be much more likely to succeed than anyone who is comparatively inexperienced. We will endeavour to get Mr. Young's personal opinion for you, and give his reply in as early an issue as possible.

Climbing French Beans (W. M.).—Undoubtedly there is a climbing French Bean, and a most useful plant it is. It may be briefly described as combining the cropping properties of the Scarlet Runner with the tenderness and flavour of the dwarf French Bean. We do not quite take your meaning in respect of "prosaic" mould. If by this you mean poor unworked soil, then we can say that neither this nor any other Bean will flourish successfully in it. If, on the other hand, you wish to convey the idea of an ordinary garden soil, thoroughly worked, and well enriched with manure, then we have no hesitation in saying that the climbing French Bean will, other details of management being proper, grow and crop in a most satisfactory manner. The height to which the plants attain varies with the soil and season. We have seen many rows only 4 feet high, and several as tall as 8 feet. You might take 6 feet as the average. Sutton's Tender and True is an excellent variety. Of course you will understand that the plant partakes of the tenderness of Kidney Beans, and must therefore not be sown early.

Dendrobiums after Flowering (W. Raby).—Plants that have flowered must be watered with great care. Injury often results in their present stage from giving them too much water. The roots of many are still inactive, and if they are kept in a wet state numbers are certain to perish. The reason many *Dendrobiums* decline in health after the first or second season is frequently owing to keeping them in a saturated condition as soon as flowering is over and the plants commence growing. They need little water at first, a slight dewing with the syringe being ample in a moist atmosphere until the formation of new roots. As the roots and growth extend the supply of water should be increased. Plants would last longer and increase in strength if greater care was exercised during the early stages, and again after the completion of growth. When *D. nobile* starts into growth it often pushes freely from the pseudo-bulb. If these are not wanted for stock they should be removed, for they have a tendency to rob the growths that issue from the base. This old but very useful Orchid delights in a moist atmosphere.

Thunbergias in Boxes (Tyro).—*Thunbergias* would succeed well if planted out in a well-drained box in a greenhouse. Sow the seed thinly in a well drained 5-inch pot filled with equal parts of leaf soil and loam, with a good sprinkling of silver sand; make the surface level sow the seed thinly, and barely cover with fine soil. Place a covering of light, damp moss on the surface, which will counteract the drying of the surface. Place the pot under a close hand-light or bell-glass in the greenhouse, and let it be kept shaded. As the seedlings appear remove the moss, and ventilate and water with care. After the seedlings are large enough to handle pot them singly in 2-inch pots, and when established in these repot into 5-inch pots. The soil at this repotting should consist of three parts turfy loam to one each of leaf soil and well pulverised manure, with a little sand. As the plants become well rooted they must not be allowed to suffer for water, and be syringed thoroughly on fine afternoons to keep down red spider, which is their greatest enemy. After the plants become well established plant out in the boxes.

Preparing Pasture Land (C. H. R.).—The ground should be trenched as deeply as the good soil will allow, but do not bury the turf more than 9 inches deep, and do not bring much of the stiff, stubborn sub-soil to the surface; a little may be brought up and the other loosened to a depth of a foot and left at the bottom. The ground after trenching should have a good dressing of decayed stable manure, and if you can command some charred refuse it would prove a most excellent dressing, as also would ashes and mortar rubbish from an old building, spreading them on the surface evenly and forking them in, but not so deeply as to disturb the turf and bring the grassy part up, as they would no doubt grow and give considerable trouble through the summer. We should crop the ground you intended planting with fruit trees with Potatoes and other vegetables that will be off by autumn. If the ground is then stirred deeply and manured it will be in good condition for planting with fruit trees. Without a sketch of the ground and the method in which you propose to lay it out, and how much you wish to devote to each crop, we could not advise you in respect of what to plant.

Vines and Manure (E. J. C.).—Basic slag was recommended for Vines as a source of phosphoric acid yielded slowly to the soil, and also for its free lime. We have no recollection, however, of advising sulphate of ammonia to be applied with basic slag, and hardly think we have done so, unless the case was an exceptional one, and of which you give no data. Replying to your present questions:—1, The dose of basic slag should not be repeated during the growing season, as the phosphoric acid will come too slowly to profit the Vines. Quicker acting substances should be used, the following being more to the purpose for feeding during growth—bone superphosphate, dry and crumbling, three parts; powdered saltpetre, two parts; and ground gypsum, one part, mixed, applying 4 ozs. per square yard when the Vines are started or commencing to grow, again when the Grapes are thinned, and again when the stoning is completed and the berries are beginning their first swelling. This, with the "pump sewage," should give excellent results. 2, The Peaches and Nectarines that have been dressed with basic slag the same as the Vines may be treated in a similar manner with the fertiliser named, but it is not advisable to stimulate the trees much in the early stages of the fruit swelling, or until they have stoned, as nitrogenous food favours wood rather than fruit growth. The mixture may be applied at starting the trees, or when the buds commence swelling; after the fruit has been thinned for the stoning, or just before this begins; and when the stoning is completed, the fruit then taking its last swelling for ripening.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (C. J. W.).—1, 2, and 4, all forms of *Odontoglossum crispum*, and not one of them is over the average of merit; 3, *O. gloriosum*; 5, *O. Edwardi*. (Amateur).—1, *Sedum Sieboldi*; 2, *Sempervivum tectorum*; 3, *Diplacus* (*Mimulus*) *glutinosus*; 4, *Allium neapolitanum*. (C. G. A.).—1, *Daphne Mezereum*; 2, *Akebia quinata*; 3, *Abutilon vexillarium variegatum*; 4, *Asplenium Ruta muraria*; 5, *Cyrtomium falcatum*; 6, *Polypodium aureum*.

Names of Fruits (H. U. R.).—No. 1 closely resembles the Red Winter Calville. No. 2 is suggestive of small fruits of Small's Admirable, but are so much bruised as to preclude certain identification. It is possible that both varieties are local seedlings, of which there are many in your county.

Green Peas as a Field Crop.

THOUGH a large proportion of this year's crop of Green Peas is, as it should be, already in the ground, there is yet time to sow some of the midseason and later sorts. Farmers are very cautious folk, and are hardly persuaded to make ventures into unknown regions, but there are many farms so situated near to large centres of population and containing soil suitable for Pea growing, where a reasonable acreage of this vegetable might be made very productive and lucrative. We say reasonable acreage. We mean with a view to the supply of labour wherewith to pull the pods the moment they are ready for market. There is generally a good supply of suitable hands in and about large towns; catch-penny hands are generally on the look out for such work; women who will work may earn three or four shillings per day, and there is an attraction to townspeople in spending a few days in the fields. In fine weather women can take their families with them and camp out, as the hoppers do in Kent. Near a town a farmer might find it easier to market 20 or 30 acres of Peas than to market one from a remote village. Then there is the advantage of having his market near at hand, so that he can get a quick sale, which is desirable, for Peas are very perishable if kept long in masses.

Growers at a distance from their market sometimes have the mortification to find that their produce has not paid for pulling and railway expenses. We have known Peas to be condemned as unfit for food, and money having to be paid for carting them away. The cause was heating from being too long in bags without removal. In other cases salesmen have to take 1s. or 1s. 6d. per cwt. for produce so as to get them removed before worse happens. The farmer who is independent of the railway, and can cart his Peas in direct, must thus have a great pull over those at a distance.

We have shown the dark side of Pea growing, now we must show the bright. We have known a crop of 6 tons per acre, and another case where 100 bags (of 8 pecks) per acre were sold, commencing at 14s. per bag and finishing at 6s., the average being about 9s., or £45 per acre. This was a 10 acre plot, and if there had been a sufficient

supply of labour none would have made less than 10s. per bag, for they were all ready at once. It is obvious, therefore, that it is unwise to have too many eggs in one basket—i.e., too many Peas ready at once. Three or four varieties coming in succession are better than one sown at different periods, for there will be more difference in the various times of maturity, and so the pulling season will be prolonged, labour will be made the most of, and although price may at first sight seem likely to suffer, the loss will be more imaginary than real, for quality should increase with the later season, midseason and late Peas being as a rule the best. The labour of preparation is more easily managed than that of harvesting, for in Pea growing districts, and taking large acreages, nearly all the work is done with the horse. The crop is generally grown after Barley, and in place of seeds. This is often done on light and dry land as a necessity owing to the Clover plant being a failure and not worth keeping further to graze or mow.

The land having been well worked and cleaned in the autumn, is manured and the manure ploughed in when convenient; on light soils this work may be put off, but on heavy or strong loam earlier ploughing must be resorted to so as to insure a greater probability of a good frost mould. The ploughing having been done with ordinary ploughs, a 9-inch seam would be the rule, and no better plan can be followed afterwards than to use the same plough and ridge the land up, taking the plough down alternate seams, so making the ridges 18 inches in width. The seed should be sown by hand in the furrows, and the operation may be best described as a rough sort of dibbling, or much as a gardener sows his garden Peas. Any top-dressing should be put on now, if at all. On light soil 1 cwt. nitrate of soda, and on any soil 3 cwt. superphosphate will be of material benefit.

The ridges should now be split, covering in both seed and manures. A casual observer might think that Peas sown thus would come up too broadcast, but such is not the case, as they are almost all in rows, and very few are disturbed by the skerrying which so soon and so necessarily follows; for to grow Peas well means to grow weeds well. The ridging defines the position of the rows of Peas so well that a horse hoe set narrow may be run between the rows before the Peas actually appear, and the sprouting weeds killed before they are troublesome. The greater exposure of soil to the influence of air and sun is an advantage, as well as the more complete burying of the seed out of the reach of predatory birds. Peas at 5s. to 10s. per peck are too costly to feed birds with.

The varieties recommended by practical Pea growers are Eclipse and William I. as earlies, but the latter is very dwarf, and is only suitable to good land in the best of condition. Telegraph is a very good midseason Pea, and stands marketing well. Duke of Albany is a little late, but the quality is splendid; nothing can beat this Pea on the market. Duke of York is a newer kind, and is likely to make a permanent name for itself. All the above are good standard varieties, and suitable for growing in the field without rods. Tall-growing Peas, like Ne Plus Ultra, are of no use for such cultivation. The space between the rows must be kept stirred with the hoe until it cannot be done without damage to the young growth.

As it would be impossible to gather field Peas in the same way that garden Peas are pulled from the rodded rows—i.e., by selecting the pods as they become fit, and leaving the rest to mature further; field Peas are pulled up by the roots, all the marketable pods stripped from them, and the straw put in heaps to dry before being carted into a stack.

Work on the Home Farm.

More stormy weather with heavy snow showers and more delay in farm work! Instead of making up the arrears they are perforce still accumulating. The worst aspect of the situation arises from the fact that the young generation of farm labourers are so much less inclined to make a push when work is backward than their fathers were. Many farmers give a rise of wages to their daily labourers on March 1st, when it becomes light enough to work from 6 to 6; but they are able to make the stipulation that such shall be the hours. It is too often the custom for the men to leave home at 6 A.M., the time occupied by the journey to the farm being included in the working hours. Unless the men all live close together this results in their dropping in at intervals, and means that little or no work will be done

until all arrive. Unless the men can be got on the ground at 6 it is much better to allow a specified time—say fifteen minutes—for the journey, and have all in the yard together. The same applies with even greater force to the time of leaving. With north winds, frost and snow there is hardly any spring growth, even where the land is not stocked; but with no Turnips farmers have been obliged to stock their seeds with ewes and lambs, and being short of plant to begin with the fields are now quite bare. Mangold has to be given, and what with the ewes and the cows the Mangold heap is fast shrinking to an end. We are hoping for warm weather soon, otherwise we shall be indeed in evil case.

It is advisable to dock the lambs' tails now, as there is danger if they get too strong. As soon as they are strong enough to stop out at night they may be docked, and there is less danger in cool weather.

We see a good many cattle out at grass now, but cannot see much economy in turning out yet, for straw is cheap, and much more plentiful than the grass, which has greater value just now for sheep. Some farmers like to get their cattle out early and hardened off, as there is an idea that they begin to thrive sooner and better if they have to watch the grass growing; but it will be a rough experience for them to be out now unless they have very rough coats. Of course they may be, and in most cases are, brought up at night; but they will be difficult to tempt with anything worse than hay or cake. Cut straw will need very highly flavouring to tempt them after they have had a few mouthfuls of grass.

A NEW ZEALAND BUTTER LAW.—In New Zealand they have a law which says, "In every case where dairy produce is condemned by an inspector he shall, at the cost and expense of the owner, cause the same to be removed to boiling down works, soap works, or other place where such produce shall be so treated as to be absolutely unfit for human consumption." If such a law was enacted in this country it would destroy the business of the "renovated butter" factories, and do more to help those who make good butter than all the oleo laws that have ever been passed. They evidently do not believe there that poor butter can be made good by washing it in acids, colouring it, and adding poisonous preservatives to it.—("American Agriculturist.")

WIRE FENCES.—The extraordinary demand for iron and steel products, and consequent high prices, is making wire fences cost much more than a few years ago, but we are not sure but they are even now the cheapest fences one can build, considering durability as well as first cost. Many use second-hand gas pipe for posts, and we think, says a transatlantic contemporary, there is nothing better if they can be bought direct from companies who take them up because of pinhole leaks that make them unfit for conveying gas, but in no way injure them for use as posts. They can be found in almost all sizes, from the inch pipe, large enough for the wire netting for poultry yards, up to a size that will carry a heavy wire for cattle fence, and if painted occasionally are neat and durable. They would help to remove a danger sometimes feared from wire fences, the conduction of lightning. The first iron post would be very likely to ground the current.

SAVING ROUGH FODDER.—A few years ago not many farmers in the corn-growing States thought of saving their corn-stover, though perhaps they turned cattle in among it to eat a little and tramp it down. Where small grain was grown the straw was thought to have very little food value, though some kept their stock half starved on it. Eastern farmers, who were thought to be very saving, seldom fed out bean straw or pea straw. Now all these are saved, and while they need more grain with them than does Clover or other good hay, it is thought economy to feed any or all of these, and by adding grain keep the animals in better condition at less cost than when hay is fed, and at the same time add to the value of the manure made on the farm. Many varieties of weeds also make good rough forage if mown down and cured before they have ripened their seeds, and to do so helps to keep the land clean, and preserve the fertility in it for more useful crops.—("American Agriculturist.")

MAIZE AS HOG FOOD.—It is not so common as it used to be, but the practice of feeding hogs on whole maize till they can hardly stand is still prevalent to a large extent. It is very wasteful of maize, and besides it makes pork that is not of the best quality, and will not sell in the markets for the highest prices. Nobody wants to eat lard, which is what such fat pork really is. This overfat pork does not waste so much in cooking as that from younger animals that have been fattened while the pig was given food that kept him growing. But this hardness of pork fat after maize feeding only shows that the animal has had fever which has dried the moisture out of the fat as fever does to all parts of the body. This overfat pork is unhealthy for delicate stomachs, and is especially bad for people who live sedentary lives. Only those working hard in the open air can, says a transatlantic contemporary, safely use it. Even the lard from overfat hogs is not so good. Since the superseding of lard by cottonseed oil, many people can eat pies and pastry made with fat who could not do so when the lard of overfat hogs was used. In olden times the fat in a hog made him sell better, as it could be tried out and sold as lard, which always brought a higher price. Now the lean hogs, with only fat enough to cook it with, bring a higher price than hogs whose bodies, except the bones, could nearly all be rendered into lard.

All Seeds sent Carriage Paid on receipt of remittance.

BARR'S PURE GRASS SEEDS

For Lawns, Tennis Courts & Cricket Grounds.

The following mixtures are composed of PURE GRASS SEEDS only, which have been thoroughly cleaned and carefully mixed. They cannot fail to give the greatest satisfaction.

The seed is sold by weight, which is the only correct method of estimating quantity needed for a given space.

BARR'S NEW MIXTURE OF DWARF GRASSES, for producing an Extra Fine Smooth Lawn.—A special mixture of the finest-leaved and dwarfest-growing perennial Grasses, producing an EXTRA FINE VELVETY TURF, and saving labour in not requiring frequent mowing. Per lb., 2/-; per 10lb., 19/-; per 20lb. and upwards at the rate of 1/8 per lb.

BARR'S "STANDARD" GRASS SEEDS, for Garden Lawns, Golf Links, Cricket Grounds, &c.—This mixture is composed of the fine leaved, dwarf growing Grasses, together with a moderate quantity of fine rye-grass, all the seeds being highly cleaned and of pure and genuine quality. Per lb., 1/6; per 10lb., 13/6; per 20lb. and upwards, at the rate of 1/3 per lb.

BARR'S "THAMES EMBANKMENT" GRASS SEEDS for Parks, &c.—A special mixture, which has been found very successful in many public and private parks and squares around London and throughout the country. Per lb., 1/3; per 10lb., 11/6; per 20lb., 20/-.

For fuller particulars and hints on the management of Lawns, see BARR'S LAWN GRASS CIRCULAR, free on application.

BARR and SONS,
12 & 13 King Street, Covent Garden, London.
NURSERIES: LONG DITTON, SURREY.

HERBACEOUS PLANTS.

MANY THOUSANDS OF PLANTS in endless varieties, including recent introductions suitable for ROCKWORK, OLD WALLS, BORDERS, BEDS, &c.

Also for damp or dry situations, LIGHT or DARK positions, SUNNY or SHADED aspects.

PLANT NOW. The most interesting and beautiful class of HARDY PLANTS.

Our Collection is being continually supplemented by rare and choice additions regardless of cost.

Manual and Reference Guide for 1900 just issued. A copy PRESENTED post free to applicants.

CLIBRANS', Altrincham.

CARNATIONS, DAHLIAS, PEONIES, Antirrhinums, Aquilegias, Begonias, Delphiniums, Fuchsias, Gaillardias, Montbretias, Pansies, Pelargoniums, Pentstemons, Phloxes, Potentillas, Pyrethrums, Violas, &c. For the best of these and all Hardy Border Flowers extant, see FORBES' ILLUSTRATED CATALOGUE, 152 pages, for 1900, free on application.

JOHN FORBES, Nurseryman, HAWICK, SCOTLAND.

PROFITABLE FRUIT GROWING FOR COTTAGERS and SMALL HOLDERS of LAND. The Gold Medal Prize Essay. By J. WRIGHT. Written for the Worshipful Company of Fruiterers. Demy 8vo, price 1/-; free by post, 1/3.—JOURNAL OF HORTICULTURE Office: 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds**

GREENHOUSES from £3 5/-; **VINERIES,** CONSERVATORIES, FRAMES, SUMMER HOUSES, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

E. B. HAWTHORN & CO., Ltd., London Works, READING. (Name Paper.)

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM

AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is **ECKFORD'S GIANT SWEET PEAS.** The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40!

Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that **ECKFORD'S SEED**, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties
PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLALED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! **ILLUSTRATED Catalogue & Cultural Notes POST FREE!** If you love Gardening send for one!

HENRY ECKFORD,
SEED CROWER, WEM, SHROPSHIRE.

BEGONIAS, TUBERS & SEED.

THE BEST COLLECTION. Catalogues Free.

Seed, Double and Single, choice, each 1/6 and 2/6 per pkt. Extra Superb Hybrid, from newest and best flowers only, each 5/-.

B. R. DAVIS & SONS, YEOVIL NURSERIES, YEOVIL, SOM.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirit to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE," is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

"WEST'S INSECTICIDE" can be proved to be the best and cheapest by sending for a free sample box.

For particulars of West's Patent "Ivorine" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Cocks, West's Fertiliser, West's Weed Killer, West's Lawn Sand, &c., &c., see ILLUSTRATED CATALOGUE of WEST'S PATENT GARDEN SPECIALITIES, post free.

Samples free; postage for samples and goods extra. All goods made on the premises by C. E. West.

Gratis, "Orchid Culture," 3rd Edition, postage 2d., Gives full particulars of the cultivation of Orchids.

THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS

Journal of Horticulture.

THURSDAY, APRIL 12, 1900.

The Journal of Horticulture can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

The Call of Duty.

ANY gardeners there are who regard the month of April as the commencement of a new year—at any rate to them it is the threshold of an era of unexampled activity of mind as well as of body. Garden plans are sometimes sketched out with April and March as the beginning and the ending, and provided such plans are skilfully made no better coigns of vantage could be chosen. Though the gardener's life is essentially a busy one, the easiest period, broadly speaking, is in the depth of winter, and even as all Nature springs into life beneath the gentle touch of spring, so must the practiser of the oldest art come forth into renewed life ready for the incessant calls that will be made upon his energies during the coming days.

It is the call of duty. And every gardener responds. We hear much of the call of duty in the navy and the army, and we read of the enthusiastic response to the country's call; but in our home life duty calls just as sternly and as persistently, and few are the laggards. Certain it is that with gardeners the man who is slow to toe the line is the one who fails—he misses the seed-time and he misses the harvest. No one who wields a pen needs to urge the gardener to do his duty to the garden in his charge, and it is pleasant to know that such is the case. There are the black sheep of the craft no doubt, but they are not numerous, and perhaps they answer a useful purpose in showing the devotion of others to their chosen avocation.

There is, however, a call of duty to which the gardener does not lend such a ready ear, and it is to incite them to this that the present words are written. The particular duty to which reference is made is that which endeavours to make some preparation for the days when the hand trembles and the eye becomes dim with the mist of years. This period must come to us all, and it behoves us to make due provision. True some of us must pass away ere yet the hand of time has put a line

of silver in our hair, but still the duty is the same, for we must do what we can for those who remain behind. The duty then lies to all intents and purposes in insurance—not necessarily in some vast insurance corporation, but in such a society as the Gardeners' Royal Benevolent Institution, which is far better, because it was formed and is maintained with only one object in view, and that is to benefit gardeners.

A season such as the present is one which does not come frequently in the history of our land. It is a season of war, and war inevitably enhances prices and increases the cost of living for everybody. The invariable tendency of such a condition of affairs is to cause a great diminution in the amount of charitable offerings, and it is not to be supposed that gardening charities will be exempt from the prejudicial influences now reigning. Hence it is desirable that both the amateur and professional horticulturists should seriously consider the necessity of making some special effort, in order that the Gardeners' Royal Benevolent Institution may suffer no serious misfortune of war in this spring of 1900 A.D. Owing to the energetic management of recent years and the greater publicity given to its operations, the Institution has progressed marvellously. With continued publicity it is reasonable to expect that its fortunes may at least be maintained at their present high level. This object, however, is only likely to be secured by a great collective effort and a keen realisation of the merits of the cause.

Now, can anyone point to another institution that gives the gardener such an excellent percentage on his investment? There are no shareholders here, no board of directors, and no splendidly fitted buildings, all of which are constantly crying out for more money with an appetite that is insatiable. Instead of these things what do we find? A committee of earnest men whose sole endeavours are to do the greatest amount of good with the funds in their hands, a secretary who is a worker and not a mere figurehead, and an office of two rooms. Could anything be more economical than this? Surely such an institution finds the support of every gardener! But no, this is not the case.

The response of the gardener to this call of duty is meagre indeed, it might almost be called a disgrace to our noble calling. What, it may be asked, is the cause of this? The reply must be sheer apathy and indifference. Men will not allow themselves to be roused in such a cause; they make no effort, but let things slide. Some of them say they will never require a pension. But are they sure? Have they an annuity that cannot fail? Others say they have a chance of the pension whether they subscribe or not. This is true, but they are eating the bread of charity, and this, to an independent man, is not always sweet. A third class asserts that as the management is in London metropolitan gardeners are the first recipients. This is pure nonsense, as the election is by ballot of subscribers all over the country.

During the past few years inestimable good has been done by the establishment of provincial auxiliaries, but these are not sufficiently numerous. Here again we find a number of devoted men, working strenuously to benefit the general gardening community. They seek no recompense for their labours—indeed, if the truth were known, it would probably reveal the fact that they were decidedly out of pocket over and above their annual subscriptions. From whatever point of view the work of the Gardeners' Royal Benevolent Institution be regarded, it is found that it is to benefit gardeners or their widows; and the more the affairs of the society are looked into, the greater will be the admiration of all thinking men. There may be some men who cannot see the good that has been, is being, and will be done; but these are purposely blind, and are rather to be pitied than condemned.

The most serious objection that any gardener can bring forward is that he cannot afford to subscribe. It has been heard many and many a time, but is it true? Everyone who is intimate with the inner workings of the craft knows that the gardener is not "made of money!" He has frequently many demands on an already slender purse. Should this, however, prevent his adding his mite to an excellent cause? By no means. Surely a little could be spared to be handed over to swell the all too limited funds of the society. What the amount should be must of course be a matter for individual decision, but it may be borne in mind that the nimble sixpence laid by weekly means twenty-six shillings at the end of the year.

"Too much" some will say; very well, reduce it by one half—three pence per week—which cannot well be deemed extravagant.

Let us make a little estimate of what the amount would be if one half of the gardeners of the United Kingdom subscribed to the funds of the Gardeners' Royal Benevolent Institution the sum of 13s. each per annum. To do this we must first ascertain how many gardeners there are, and to this end we will make use for a moment of the "Horticultural Directory." This book does not embody all the gardeners by several thousands, but it will do for the object in view. To the alphabetical list of gardeners we find eighty-eight pages devoted, and estimating each of these pages to contain eighty names and addresses we get a grand total of 7040. Supposing each of these subscribed the suggested 13s., the amount would be £4576—a handsome sum indeed, but not too large for the committee to employ to the general benefit of the craft. Doubtless there are three times the number of gardeners, so that the estimate cannot be termed an unreasonable one.

Gardeners of Great Britain and Ireland are called upon to think of these things. Let them ponder deeply over the figures given in the preceding paragraph, and decide to answer to this call of duty. If they do not care to send their mite to headquarters, they must seek the nearest auxiliary and place their subscriptions in its hands. There may not be a convenient auxiliary, but one can soon be formed if a score or more of determined men set themselves to the task; they can always get valuable assistance to such ends as these from Mr. Ingram, 175, Victoria Street, London. Those men who come forward now can rest assured that they could not work for a better cause—a cause of which, though they, personally, may never have the need, hundreds of their brethren of the craft will participate in and receive benefit from in the years that are to come. Gardeners, duty calls you—the noblest duty of all, for it is that which extends the hand of assistance to others in distress. Who will not answer to the call?—A. B.

The Queen in Ireland.

FLORAL decorations played, perhaps, only a minor part in the magnificent reception given to our Queen by the Green Islanders on Wednesday last (April 4th), when her Majesty after long years came back to Erin, and it is a question whether they were sufficiently in evidence to warrant a note for the *Journal of Horticulture*. They may, however, serve as an excuse to voice in its pages the depth of feeling which now permeates the Milesian metropolis. Ah! You "can read it all in the papers, and do not want a gardener's description;" he could never do justice to that wild wave of enthusiasm which accompanied the Queen along "the rocky road to Dublin," where my Lord Mayor, with ancient pomp and pageantry, admitted her Majesty by the finest piece of decorative work of all—viz., a reproduction of the old city gates.

Really floral decorations, when one comes to think of it, were almost conspicuous by their absence, yet not wholly so. Here and there, at rare intervals indeed, some simple decoration in which evergreens were a prominent feature formed a pleasant relief to the thousands of flags which fluttered o'er the ten mile route. The more we were beflagged the more we missed that one touch of nature which would have harmonised so well with the bravery of bunting—viz., evergreens. Little compensation was to be found in the costly floral arch in which Booterstown displayed its ingenuity and expressed its loyalty, for although the most elaborate thing of its kind, the bulk of the flowers of which it was composed were of the "papyrus crinklum" variety, Mr. Carroll adorned the unpretentious entrance to Dornden, over whose garden he presides, by a happy blending of nature with art, in the use of evergreens tastefully draped about the old Irish motto, *cead mile failte* worked in white letters on a red ground. Evergreens, certainly, are not, strictly speaking, floral decorations, but in no instance could their importance as decorative subjects have been better shown than in the examples seen.

It is reported that on landing at Kingstown her Majesty expressed a wish for some Shamrock to wear, which was immediately supplied from the sward outside the landing place. We did not notice the emblem in the excellent view of our Queen as she drove by, but saw in the carriage beside her a charming bouquet of Callas and Lily of the Valley which had been presented at the pier. A silver basket filled with Roses, Orchids, and Ferns was further presented by the Lady Mayoress at the gate of the, then, most beflagged city of the Empire. As for the weather, which as much concerns our Journal readers as it was a matter of concern to Dublin that day, with the exception of a slight shower it was perfect, and in striking contrast to the day previous, when hopes went to zero, and although a north wind cooled the bright sun rays, it was fully atoned for by the warm Irish welcome accorded to our Queen, God bless her.—K.

*Odontoglossum triumphans.*

WITH the immense strides that have been made in the *Odontoglossum* family during late years it would be a matter for surprise if the handsome *O. triumphans* had not come in for a goodly share of attention. This extraordinary advance in quality is owing largely to the efforts of hybridists, and again to the very much improved methods of culture that are now adopted. The latter has meant that excellent introductions, which in earlier Orchid days were practically spoiled by bad cultivation, are now improved under the fostering and intelligent care that is devoted to them. Not only are the flowers finer in themselves, but better qualities are, so to speak, forced from them by rational treatment in the hands of experts. This theory of improvement by cultivation is admirably illustrated in *Odontoglossum triumphans*, of which the earlier forms were small in size, narrow in the sepals and petals, and thin in texture as compared with the splendid types of the present day.

Amongst those who have been instrumental in bringing forward marked developments in *O. triumphans* must be named Mr. de Barri-Crawshay of Rosefield, Sevenoaks. This enthusiastic amateur derives the greatest possible amount of enjoyment from his hobby, and at frequent intervals brings the fruits of his labour of love to the meetings of the Royal Horticultural Society at the Drill Hall. In April of 1895 *O. triumphans* Lionel Crawshay was exhibited, and was stamped with the hall mark of excellence by the receipt of a first-class certificate. This variety is magnificent in all respects. The flowers are large and very rich in colour. The sepals are clear yellow, with a bright brown patch and yellow margin, the petals, which are broad and of great substance, being of the same rich colour. The lip has a yellow fimbriated margin, with a broad reddish brown patch and a canary yellow throat. Though five years have elapsed this variety still maintains its position in the front rank of *O. triumphans*.

Now it is to have a worthy companion in *O. t.* Raymond Crawshay, and the brothers may be congratulated upon their namesakes. As better indication of their excellence, we give in fig. 82 a representation

FIG. 82.—*ODONTOGLOSSUM TRIUMPHANS* LIONEL CRAWSHAY.

of *O. t.* Lionel Crawshay, and in fig. 83 one of *O. t.* Raymond Crawshay. The newcomer was exhibited by Mr. Crawshay before the Orchid Committee of the R.H.S. on March 27th last, and that body

showed its appreciation by the recommendation of an award of merit. It is indeed a superb flower, as well in substance and size as in form and colour. It is fully 3½ inches across, and the golden yellow colour is practically obscured by the varnished brown. In the fine petals there is rather more yellow observable, but the brown is equally as pronounced. The lip, too, as may be seen by glancing at the illustration, is very beautiful. We have now only to wait for Mr. Crawshay's third form to complete a perfect trio.

Angræcum (Aeranthus) Leonis.

On the occasion of a recent visit to Clare Lawn I was delighted to find this beautiful Orchid in flower, and should like to know why it is apparently accorded such a meagre share of attention. Whether it finds a place in all collections or not I cannot say, but I do know that it is comparatively seldom I have seen it in flower. If its culture

FIG. 83.—*ODONTOGLOSSUM TRIUMPHANS* RAYMOND CRAWSHAY.

presents certain difficulties, these are not apparent at Clare Lawn, where it was flowering most satisfactorily. The habit of the plant (fig. 84, page 303) is very dwarf, the leathery leaves being about 6 inches long and sword-shaped; the spikes carry from two to six flowers, which are ivory white in colour. *Angræcum* or *Aeranthus* Leonis was discovered by Mons. Leon Humbolt in the Comoro Islands about fifteen years ago, and it may be grown in the warm or East Indian house in baskets of sphagnum moss.—VISITOR.

Masdevallia leontoglossa.

Few will deny the beauty of this *Masdevallia*, and yet it is not a showy plant. From a tuft of leaves about 6 inches high the flower spikes are thrown up, each blossom being greenish-yellow with purple markings, a rather unusual combination. The specific name is given on account of the supposed resemblance of the sepals to a lion's tongue. It should be accorded a position with the warmer section of the genus, such as *M. Chimæra*, at least during the winter months. In summer it can hardly be kept too cool, being a native of Venezuela.

Lælia cinnabarina.

There are very few brighter or more beautiful Orchids in cultivation than this, its brilliant red blossoms being plentifully produced on the spreading spikes. Its fine colour has led hybridists to use it freely as a parent, but beautiful as are some of its progeny, none is really so effective. It likes a light position in the Cattleya house, and should not be disturbed at the roots oftener than is really necessary. Ample moisture is required when growth is active. A native of Minas Geraes, it was introduced in 1836, and flowered for the first time in this country in a Surrey nursery the year after.—H. R. R.

Seeds and Seed Sowing.

THE month of April may, to a certain extent, be regarded as the commencement of the gardening year, as it is in this month that an immense amount of work has to be carried out. In no section of the craft is this more emphasised than in the department for sowing seeds of various kinds with a view to raising flowering plants or vegetables for the adornment of one position, and the stocking with utilitarian products of another. There can be no doubt that good seeds of the best kinds with timely and careful sowing contribute very materially to successful culture. The good seeds are to be obtained with a tolerable degree of certainty from every respectable seedsman, but the sowing is unfortunately only too often so badly done that failure is inevitable. Many and repeated failures have taught me how to exercise the necessary caution and care to insure success; I have been several years learning the lesson. Other persons may be better able to steer clear of rocks and shoals than I have done, but mistakes occur so easily that a danger signal or two cannot prove other than useful.

Neither a close heavy soil, nor a light poor soil, is a suitable medium for the vegetation of seeds. Enrich both by repeated heavy dressings of manure and leaf mould, and render them open and free by an abundant admixture of some hard, gritty substance, such as stone chippings, shattered brick, or, best of all, coal ashes; then by digging in autumn and exposing as much as possible to the action of frost, you will find the ground in readiness for the seeds on the first fine day in spring. This is a thorough and efficient method, preferable to any other, but unfortunately it is not always practicable, makeshifts having to be resorted to in many instances, and when such is the case "little and good" rather than "much and bad" should be our motto. Instead of scattering broadcast such few fertilisers as our limited means can command, we must concentrate them in drills, trenches, and stations, so as to have the requisite amount of nourishment within reach of the earliest roots which spring from the seed as it vegetates.

Take, for example, a row of Peas. Now the Pea is a deep-rooting gross feeder, with a free, quick, succulent growth: why, to sow the seed of such a vegetable in a poor, inert soil, is ridiculous—it is sheer waste, and it is quite certain to cause vexatious disappointment, and yet there can be no doubt about its being done season after season. Whereas we have only to make a trench a foot deep and wide, laying the excavated soil along the sides, replacing about two-thirds of it with manure, leaf mould, or other decayed vegetable matter, or in fact any substance which appears to us to be sufficiently nutritious for the purpose, then mixing enough of the displaced soil with it to fill the trench. We next draw a deep drill along the centre, deeper than is absolutely necessary for the seed, which is much too precious to be left to take its chance in such a rough mixture; so we look about us for some old leaf mould, wood or coal ashes, fine charcoal, shattered brick or stone siftings, making the best mixture of any of these we can find, scattering an inch or two of it along the bottom and sides of the drill; then comes the seed with a covering of the same fine gritty substance pressed gently down with a spade, and the work is done so well that we may feel certain vegetation, and a free robust growth, will promptly ensue. We have thus laid the foundation of success, but we must not forget the risk which the seed runs of spoliation from mice and birds.

I am not afraid of the ravages of snails in such a quick, free soil; it is in a cold, heavy, inert soil, that they do so much harm. There are some favoured spots where mice and sparrows are so scarce as to be comparatively harmless, but in most gardens these pests are so rampant that they cannot be ignored. I have a lively remembrance of the keen mortification of a certain worthy amateur who, after incurring the expense of wire guards, lost the whole of his first sowing of Peas from mice, which were screened from observation by the guards. When protection is necessary I much prefer sheets of glass laid singly end to end along each row, with a wire stretched over them to prevent the wind blowing them away, letting the plants lit the glass as they rise above the soil, thus starving out the mice and tantalising the sparrows. Failing the glass we may resort to pieces of slate or roofing tiles, being careful, however, to remove them immediately the Peas reach the surface, and using wire guards or netting to keep off the birds; the seed vegetating under such opaque coverings quite as readily as it does under glass.

For smaller seeds, such as Cauliflowers, Brussels Sprouts, and kindred subjects, make the drills deeper than usual to afford space for an inch or two of the same gritty substance as was used for the Peas, enveloping all the seeds in a precisely similar manner; also take especial care to put netting over the seed beds a few days after sowing; birds' eyes are keener than ours, and they will detect the sprouting growth long before it is visible to us. I have known sand to be used very successfully for covering seeds, but I hesitate to recommend it, for in ironstone districts the whitest sand usually contains sufficient oxide of iron to destroy the seed germs as they start into activity; sometimes the young growth will force its way

through the sand, but even then the delicate cuticle of the stem suffers so much from contact with the sand that the plant soon fails. For Carrots, Parsnips, Beet, and Salsify it has been shown long ago that holes filled with fine, rich, gritty soil for each root insures a crop; the plan is a tedious and laborious one, which we would gladly dispense with at this busy season of the year, and is only recommended when failure is inevitable without it.

A greater amount of success attends the general culture of flower seeds, because many of them are raised under glass in pans; but even with this advantage a little extra care makes all the difference between success and failure. Very minute seeds, such as of Gloxinia and Begonia, answer best if sown on a damp surface and left to vegetate uncovered with soil; but then excessive evaporation must be checked, for if they are exposed to the sun or any parching influence watering will be necessary, involving much risk of washing away the seed; moreover, to suffer such seed to become very dry just as vegetation takes place is to destroy it. The best plan, therefore, is to place the pans in a genial temperature, and to exclude light from the seed till growth begins. Formerly I used pieces of muslin, but now prefer sheets of thick paper placed upon the tops of the pans immediately after the seeds are sown, and thus avoid all risk of failure.—L. E.

Vine Extension.

It is undoubtedly true that the more latitude and freedom allowed to the shoots of a Vine the longer will the latter continue in good health and bearing. This is evidenced by the remarkable specimens to be seen at Hampton Court, Cumberland Lodge, and Manresa House, Roehampton. The former is about 130 years old, the next mentioned (propagated from it) has reached the age of 100, and the latter is, I believe, nearly forty years. All of these are still vigorous, and annually bear large crops of fruit. That this would not be the case had their growth been more restricted is not difficult to believe. It is recorded by travellers in the East, that in some parts of Palestine the Vine grows most luxuriantly, developing into trees with stocks 1 foot in diameter, and yielding bunches of enormous weight.

In the cultivation of the Vine in our glass houses at home, its development under natural conditions is, I think, not sufficiently borne in mind. I know well that the shoots must be kept within certain bounds, but in my opinion the latitude allowed them is often not nearly so much as ought to be and might be given. In the first place, permanent Vines are frequently planted too thickly. A distance of 3 feet 6 is not too much to allow between late Vines, though early forced ones may be placed 3 feet apart. Instead of following the usual practice of planting permanent Vines at intervals along the front of the house, I would suggest that temporary ones be put there, and that two plants, to ultimately fill the whole vinery, are planted in the centre of this latter, about 4 feet apart.

The method of training I would recommend is to allow the canes to reach the top of the house as quickly as is consistent with the proper development of fruit spurs at the same time, and then to train the rods in exactly opposite directions—i.e., towards each end of the vinery. Eventually, at distances from 3 to 4 feet, lateral canes, at right angles to the above, would be allowed to grow down the trellis to the bottom of the vinery. Such a system of training is advantageous, because the temporary Vines are not interfered with in the least for some years, and would not suffer at all from the presence of the permanent ones. The former, of course, would be gradually removed as the latter advanced.

It is generally recommended that the growing shoots of a Vine are best stopped at two or three leaves beyond the embryo bunch. I think it is a mistake, however, to lay down a rule at all for this work, for the more healthy foliage that can be developed the better will the plant be able to thoroughly mature its crop of fruit, and the amount of foliage there is room for must be determined by the cultivator. Important as it is that shoots in their young state should not be excessively pinched, it is also most necessary to exercise care in this matter when a crop of fruit is developing. One gardener—a few years ago a prominent and successful exhibitor of Grapes—used to allow his Vines to grow at will when bearing fruit. The shoots would even reach down the back wall of the vinery, so luxuriant did they become, and the success of this practice was evidenced by the numerous prizes awarded to Grapes cultivated by this gentleman.

The direct action of sunlight upon the berries in the processes of colouring and ripening does not appear to be so necessary as that of air undoubtedly is, for even when Vine shoots are shortened considerably more than advocated by the writer, very little sun is able to penetrate between the large fully developed leaves. I do not see, therefore, how the treatment above mentioned can be otherwise than beneficial to the welfare of the Vine and its crop of fruit.—H. H. T.

London Gardens over Fifty Years—No. 21.

WHEN the growth of the metropolis forced many nurserymen to migrate where land was cheaper and smoke less abundant, they had choice of localities around the villages or small towns at an easy distance. Kent, the garden of England, might well have its attractions, so might sunny Surrey if the flats of Essex are not inviting, but Middlesex, in some respects, has most advantages. Accordingly we find that though both Kent and Surrey have some nurseries near London, a greater number are located in West Middlesex, with a few of note are in the north of that county. Entrenched about such places as Hampton, Isleworth, and Twickenham, adjacent to the Thames, nurserymen may as yet defy the aggressive builder and compete successfully in the market with those who send in supplies from long distances.

Fifty years ago only a small show of nurseries was observable in these localities, and few orchards, but there were some market gardens. Two or three nurseries, which dated from the time of George III., have gone and left no trace. There was the establishment of Ronalds & Son of Brentford, to take one instance (Scotch folks again, I suppose), which Loudon mentions as of repute for its fruit trees and evergreens. Twickenham was famous in Loudon's time because of its hundreds of acres of Strawberries, but it has a less extent now. "I roamed all about Strawberry Hill," said a friend sorrowfully after a summer visit; "the place is pretty enough still, but I never saw there even one Strawberry."

We should naturally think that the Thames valley and its near localities would be well suited for plants of the Liliaceous and allied tribes—in fact, many are grown, both in Middlesex and Surrey, along the river. The cultivation of showy flowers often pays better than that of vegetables, especially such plants as are brought forward under glass. Therefore, we see fewer plants now in the open than formerly; quantities of hardy species in bloom come to market from districts where land can be rented cheaply. Crocuses have been largely grown under fruit trees, also in raised beds, which sometimes occupy half an acre of ground, the common yellow, blue, and white being mostly patronised. Some Lilies are also set in open ground, then lifted and potted before they bloom; but in many nurseries it was usual to pot them during the autumn, in soil composed of fibrous loam, cow manure, and leaf mould. They were put into cool pits or houses, allowed plenty of light and air and not much water till the shoots made their appearance. Heat was given after the buds began to show. Narcissi have been grown largely along the Thames valley, finding a place in orchards, or sheltered corners near walls. We have noticed the Pheasant's-eye Narcissus planted in rows with Moss Roses, as being usually over before the Roses are leafing. The Paper-white species, *N. papyraceus*, with its small pure white flowers, is earlier, blooming naturally about February. Many others of the Narcissi imported from Holland are forced in various ways.

The neighbourhood of Twickenham is rather prolific in bulbous plants. Amongst its nurserymen I remember Messrs. Hawkins and Bennett, whose establishment bore at one time the name of Lily Gardens. Twenty years ago they were large cultivators of the Stephanotis, and in 1879 they had the Banksian medal awarded them for a group of Pelargoniums, including Vesta, a new double scarlet Zonal. Some of the folks there used to grow the Arum Lily by planting them out of doors during the summer, forcing them later on. At Acton, however, Reeves upheld the plan of growing them wholly in pots; this became the common method. He had a grand show of blooms in his houses a few weeks before Easter. *Richardia maculata* was first brought out, I believe, at the West London Nurseries; admired for its spotted leaves, it has not gained the popularity of our familiar *R. æthiopica*. Then, half a century ago, the Roman Hyacinth, much in request now, was not much known. It does not seem to have come to us from Italy, unless by way of France or Holland. Nurserymen soon discovered a succession of blooms could be easily and profitably forced. The usual London method has been to place the bulbs thickly in boxes, covered with spent hops or cocoa-nut fibre refuse; they are kept out of doors till about 2 inches high, then by the aid of warmth the spikes rapidly appear. A blue variety of this Hyacinth has not been much patronised yet.

About Christmas some folks pay 5s. or more for a pot of Lilies of the Valley; while I am writing they are cheaper, and from farther up the Thames clumps of them go into the homes of workers at Bermondsey, Lambeth and other busy suburbs, where we see them displayed in windows. But, in some districts, pots do not satisfy, the people contrive to have, possibly in a small front garden, a little bed of the plants carefully guarded against cats and children. Sparrows do not touch Lilies of the Valley, deterred probably by the acridity of the juice. With management these are coaxed to put forth at least a few flowers every season. There have been shady nooks along the Thames in which the plants were raised out of doors, bunches of the

flowers being sent to market during the spring, but they are now brought on under glass from imported crocus. For the early demand single crowns are forced; for the later, clumps of the plant having a dozen buds or more. The London growers have found, as their Dutch friends pointed out, that too rapid forcing is apt to make some of the best crowns turn blind.

The year 1900 will be remembered as one in which the old controversy about the Shamrock was revived, owing to the general

FIG. 84.—ANGRECUM LEONIS. (See page 331.)

wearing of it on March 17th. It is never likely to be settled, yet there is strong evidence in favour of some Clover, probably the common spotted-leaved *Trifolium repens*. No doubt we might agree to adopt any plant and say that henceforth shall be the Shamrock. Many have believed in the Wood Sorrel just because it is found about Irish boggy woods; also the plant seems to have had sacred associations, for Gerarde calls it not only Cuckoo Meat, but "Alleluiah," because it flowered near the time when Alleluiah was said in the churches. It seldom opens till the end of April. The plant still grows freely in some parts of Epping Forest. Books on gardening, not very ancient, mention the Wood Sorrel as cultivated for salads and mixing with boiled greens. It was propagated by dividing the bulbous roots; and planted in the shade, by keeping it from coming into flower, gardeners managed to cut a succession of fresh leaves till October.

Only a small proportion of the Violets sold in London at this season come from its rural suburbs, yet some are grown near them, as about Richmond, Teddington, Twickenham, and places adjacent, beds of Violets being often formed in orchards. A bank sloping towards the south will give a fair quantity of blooms in an average autumn. Of course for a winter supply the plants must be kept in houses or pits; they only require a moderate warmth. After the third year most London growers pull up the plants and make new beds, because the flowers degenerate by that time. Though as a fact the roots of Violets do not go down deeply, they flourish when there is underneath them some depth of good soil. Mostly the plants are put in rows, alleys being formed, so that the flowers may be gathered without treading on them. Part of the Wallflowers now coming into the market are grown about the western suburbs, such as Twickenham and Isleworth; they are found to thrive best in shady places, and as a rule they are treated as annuals. Seeds are sown in February, and when the young plants are big enough to handle they are placed in rows about 12 inches apart. Some of these rows may be seen nearly half a mile long. The darkest coloured Wallflowers are still most liked; also they are found to bloom better and earlier.

To London gardeners of the present he is simply a name, but those of the forties or fifties, many of them, knew well Wilmot of Isleworth. He was extensively engaged in forcing, and outdoor culture too. I think he had above 100 acres of land when I first heard of him. Amongst his specialities was Wilmot's Early Forcing Bean, which he grew largely. Pines he cut every day of the year; his were mostly forced in pots, plunged in fermenting bark, in narrow houses slightly sunk in the ground. Of Vines he had an immense quantity; a few on walls, the bulk under glass. The Black Hamburg was the kind he favoured more than others, but he showed the Mill Hill Grape, which he appears to have named and found productive, so had several houses devoted to this sort. Mr. Beck's nursery at Isleworth used to send out every year a variety of Pelargoniums raised from seed; he also had some choice Orchids. Amongst the modern nurserymen of the district we remember Abear, Lee & Son, and Weathers. In a former article, dealing with part of the West of London, I should have referred to Mr. Buller, of Kensal New Town, who was, twenty years ago, a successful grower of Agaves, Aloes, and miniature succulents.—J. R. S. C.

Fatality Among Broccoli.

A COMBINATION of circumstances has once again borne testimony to the uncertainty of winter and spring Broccoli, the dearth of which, as well as some other vegetables, being such, that the gardener's lot at the present time is anything but an enviable one. The fatality among Broccoli is more directly attributable to the severity of the winter's frost, and notwithstanding that the frost spells were of short duration, the injury inflicted is now only too clearly apparent in patchy beds and bare ground. There are invariably more or less heavy losses when frost exceeds 20° on several consecutive nights, and this has happened at two or three different periods of the present winter.

The effects of the frost have been accelerated without doubt by their late growth, consequent on the prolonged drought of last summer, followed by autumn rains and mild growing weather. The latter sustained leaf development, and consequently a sappy nature in the stems and heart of the plants until quite late in the winter, and such severe frost following closely on this could not be expected to be other than fatal in its effect. It is five years since there were such a poor crop of outdoor vegetables, and that winter was noteworthy for the prolonged and deeply penetrating frosts. Then there were almost continuous frosts for well-nigh three months.

All varieties have suffered severely, but needless to say the early Broccoli are those which fared the worse. Of some varieties there were whole breadths completely destroyed, in others few remain. The late ones, such as Late Queen, Veitch's Model, Continuity, Knight's Protecting, Sutton's Bouquet, and Southampton Late White, are some of those which are present in irregular numbers, but in none is there a full row. This not only constitutes a great loss of labour, but it entails such a loss of material, and, moreover, there is an absence of a vegetable so indispensable for the dining-room, reducing the supply to a state of monotony. Every care was taken to choose firm soil for this crop, and it is very distressing to see one's stock dwindling down in some kinds to nothing, after so much time and labour have been spent on sowing and planting. One almost despairs of planting Broccoli at all.

Where there are vacant glass structures or spaces in them that can be utilised for lifting and storing the early varieties, a supply can be maintained for some time, but this is not a frequently met with convenience in private gardens. It has happened that following such

winters as the past one, resolutions are made not to grow so many Broccoli, and this, when acted upon in summer, is regretted when the winter comes and does not prove severe. It is best to take the seasons as they come, and not to relax efforts because of failures. Severe winters are not often succeeded by others of the same nature. Snow is generally looked upon by the inexperienced as a blessing in disguise as regards outdoor vegetation, but this certainly does not apply to Broccoli so favourably. In its melted state it settles in the hearts of plants, and is overtaken at night by scorching frost, and to this cause much of the dearth of Broccoli is due at the present time.—W. S.

Culture of Nephrolepis.

WELL developed examples of this Fern are among the choicest plants for decorating a shady corner in the conservatory in summer. Although a stove evergreen Fern, being a native of the tropics, it succeeds very well in an intermediate temperature, and may be employed in structures where there is but little heat in summer and autumn other than the natural temperature.

The Nephrolepis lends itself readily to propagation, both by division of plants at the present time, or by pegging down some of the best of the creeping stems which are thrown out by vigorous healthy plants from the base. In the latter case drain some 3-inch pots and fill with a mixture of peat, loam, leaf soil, and sand. Fasten down young plants upon this, allowing them to remain attached to the creeping stem until rooted and independent plants are formed. Divisions to form new stock may be taken from the outside of large old plants, but the most vigorous are best found on younger specimens which have not been root-bound for so long. The fronds attached to the most suitable divisions should be comparatively short, fresh, and green. Large yellow fronds attached do not serve any useful purpose, and should be cut off if present. Place the pots on a damp base in heat and moisture, syringing lightly every day until established.

Young plants may be given a shift when roots are becoming numerous. Spring is usually the best time, root activity increasing daily, inciting new fibres to take possession of the new soil. Plants established in pots from 5 inches to 9 inches diameter are the most useful and portable for decoration, while for forming large specimens 10 to 13-inch pots may be employed. Of course the plants must be gradually moved on to the larger sizes. Water sparingly immediately after potting, rather maintaining the soil moist with gentle syringing than saturating the new compost with too free watering. The fronds being long and narrow are liable to fall about if not lightly held together with a strip of matting run round three or four slender stakes.

The Nephrolepis also makes an excellent basket Fern. *N. pectinata*, *N. davallioides*, and *N. davallioides furcans* are the best varieties for growing in this way. Wire baskets should be used, lining these with a layer of sphagnum moss. Utilise plants of a size corresponding to the baskets, and which will admit of a fair quantity of compost being introduced for them to root in. Hang up the baskets in a warm moist atmosphere, and syringe daily. Heavy watering will not be needed at first, simply keeping the moss and the soil healthfully moist. Shade from sun. When well established in the receptacles large and imposing specimens are formed, which prove attractive for some years. As the Nephrolepis is an evergreen Fern, it is ornamental the year round so long as the fronds are healthy. When the roots have permeated freely into the compost, and this is indicated by the vigorous condition of the new fronds, the baskets may be suspended in a cooler temperature than they were in previously.

Watering is of importance; therefore, in placing the Ferns in the baskets keep the crowns fairly low down, and do not fill in the soil to the top, so that there remains ample room for watering. However, with this attention the baskets are liable to dry through rapidly, and the ordinary method of watering fails to moisten them. Under these circumstances soak the basket in a vessel of water. It may not be necessary to do this the first season, except the baskets are very small.

Besides *N. davallioides* and its robust crested form *furcans*, above mentioned, we have in *N. Bausei* a pretty variety; *N. Duffi*, which ought to have been mentioned as a good basket variety, is exceedingly ornamental. The fronds are peculiar, the pinnæ being of rounded shape and closely set on the midrib. Each frond is several times divided before the tip is reached, and each division is also branched at the tips. The growth is tufted and of close habit. A very distinct variety, differing entirely from the varieties mentioned, is *N. rufescens tripinnatifida*. The pinnæ are closely set and overlap each other to some extent, which gives the frond a very full bold appearance. *N. exaltata* is also a well known handsome variety, and should be included in every collection of stove Ferns.—E. D. S.

NOTES & NOTICES

Recent Weather in London.—The weather in the metropolis during the past few days has been decidedly pleasanter owing to the cessation of cold winds. Both Saturday and Sunday were fine on the whole, though the sun did not shine very brightly. On Monday morning it was quite foggy, but the sun shone brilliantly later. Rain fell rather heavily in the evening, but it was not cold. Tuesday was an ideal spring morning. Wednesday opened dull, and was inclined to be showery.

Weather in the North.—On three mornings of the week ending the 9th inst. frosts of 2°, 3°, and 4° occurred, the last on Sunday morning, when the hoar frost was very dense. The days have been alternately dull and bright, and occasional showers have fallen. Cold easterly winds have generally prevailed, but on Monday the wind changed to the west, bringing intermittent cold showers.—B. D., *S. Perthshire*.

Royal Horticultural Society—Special Notice.—Notice is hereby given that a general meeting of the society will be held at 117, Victoria Street, Westminster, on Wednesday, April 25th, at 2 P.M. (i.) To consider, and sanction if approved (either with or without addition, omission, or alteration), certain new by-laws rendered necessary by the Supplemental Charter lately granted to the society. (ii.) To consider and adopt, if approved, the following resolutions, viz.:—(a) That in accordance with the recommendation adopted unanimously at the annual general meeting to celebrate the centenary of the society by removing the gardens from Chiswick, this meeting adopts the proposal of the council to purchase a freehold site in the parish of Limpsfield, in Surrey, and authorises the council to take the necessary steps for acquiring the said site, and for developing new gardens thereon. (b) That this meeting authorises the council to enter into negotiations with and to obtain the co-operation of the Board of Agriculture and Horticulture, the University of London, and the County Councils, with a view to the establishment in connection with or in affiliation to the society, of a representative School of Practical and Scientific Horticulture; the scheme to be duly submitted to the Fellows for approval. N.B.—The Supplemental Charter and the new by-laws will be printed in full in the next number of the Society's Journal, vol. xxiii., part 3. Fellows requiring an advance proof of the by-laws can obtain it on personal application at the society's office. By order of the council.—W. WILKS, *Secretary*.

Scottish Horticultural Association.—The monthly meeting of this association was held in the rooms, 5, St. Andrew Square, Edinburgh, on April 3rd. Mr. M. Todd, one of the vice-presidents, presided over a large attendance. The lecturer of the evening was Mr. David P. Laird of Pinkhill Nurseries, Edinburgh, and his subject was that of "Ornamental Trees and Shrubs for Town and Villa Gardens." As Mr. Laird remarked, the subject was too extensive to be treated in detail, but the manner in which he dealt with it showed a careful grasp of the wants of town and villa gardens, and how they could best be met. The several heads of the paper covered the leading factors in the problem of the best things to plant and under what conditions they should be planted. The paper was of a high order of merit, and was made all the more agreeable by the humorous hits at his own occupation and those who followed it. A valuable suggestion for those about to build a house was that the architect should set apart a sum for the planting of the grounds, so that the extras which always occurred should not absorb all the amount intended to be spent, and was supported by a quotation from Mr. Lorimer, a well-known architect, to the same effect. The Lime was mentioned as an unsuitable tree on account of its size and the early date at which its foliage became sickly looking. A lively discussion followed, taken part in by Messrs. Arnott, Murray, Fish, Lonie, Grieve, and others. Mr. Fish made a vigorous and poetical defence of the Lime. The chairman made a valuable contribution to the discussion, and Mr. Laird was accorded a hearty vote of thanks. It is proposed that the annual excursion of the members be to Keir in June, if it can be arranged.—S. A.

Midland Daffodil Society.—The exhibition at the Edgbaston Botanical Gardens is fixed for Wednesday and Thursday, April 25th and 26th. Notice of entry for competitive exhibits must be received not later than Monday 23rd (as Rule 2), but where entries can be made the previous week it will help very much. The committee hopes to hold a conference on the morning of the second day of the show, and would like to meet as many members as possible, when any suggestions could be brought forward and discussed. Exhibitors are requested to note that the non-naming of flowers may lead to disqualification. The secretaries are Messrs. J. Jacob and H. Smith, Tenby Street, Birmingham. The National Auricula Society (Midland Section) will hold its first annual exhibition in connection with the above on the first day only.

Birmingham Gardeners' Association.—At a recent meeting of the members, presided over by Mr. Walter Jones, Mr. F. W. E. Shrivell, of Thompson's Farm, Golden Green, Tonbridge, was responsible for an interesting and instructive essay on "Chemical Manures in the Kitchen Garden." The lecturer gave statistics adduced from some important experiments on a large scale which he had undertaken during a period of several years upon the comparative values of dung and chemical manures in regard to especially Asparagus, Broccoli, Brussels Sprouts, and Rhubarb, the latter both naturally grown and forced. Of fruits, Damsons and Strawberries were specially recognised. Potash or kainit was pronounced to be not suitable for the Strawberry plant, and the variety experimented on was Royal Sovereign.

Wolverhampton Floral Fete.—The dates fixed for this popular exhibition are July 10th, 11th, and 12th, and full particulars and schedules may be obtained from the secretary, Mr. W. E. Barnett, Snow Hill, Wolverhampton. It is the rule of this society to offer excellent prizes, of which £50 for a group of miscellaneous plants, and £45 for sixteen stove and greenhouse plants may be quoted as examples. This year five new classes have been added, of which one is for a collection of Orchids, with £24 to be given in three prizes; one for twelve bunches of Roses with £10; one for a collection of pot Roses with £18; one for a collection of hardy herbaceous plants with £4 4s.; and one for a floral display with £13. To the first prize in the last named class a 25-guinea challenge trophy will be added. These five classes alone, with such generous prizes, ought to be sufficient to make a show in themselves.

The Royal Meteorological Society.—On Tuesday, the 3rd inst. the Royal Meteorological Society celebrated its jubilee, having been founded on April 3rd, 1850. A commemoration meeting was held in the afternoon at the Institution of Civil Engineers, Great George Street, Westminster, Dr. C. Theodore Williams in the chair. There was a large attendance, including delegates from a number of other scientific societies. In view of the jubilee the late Mr. G. J. Symons, F.R.S., was elected president at the annual meeting on Jan. 17th, but owing to his being seized with paralysis he was obliged to resign the office. Dr. Williams, in concluding his address, stated that Mr. Symons had bequeathed to the society £200, as well as the bulk of his library. Brief addresses were delivered by Prof. J. J. Thomson, F.R.S., on behalf of the Royal Society; by Mr. E. B. Knobel, president, on behalf of the Royal Astronomical Society; by Mr. J. J. H. Teall, F.R.S., president, on behalf of the Geological Society; by Mr. R. C. Mossman, F.R.S.E., on behalf of the Scottish Meteorological Society, and by Mr. A. Wynter Blyth, M.R.C.S., on behalf of the Sanitary Institute. Prof. Dr. G. Hellmann presented an address from the German Meteorological Society, and also spoke in appreciation of the valuable work done by the Royal Meteorological Society. In the evening a conversation was held at the Royal Institute of Painters in Water Colours in Piccadilly, the guests being received by the president and Mrs. Theodore Williams. An exhibition of meteorological instruments was arranged in the banqueting room, and lantern demonstrations were given. The Royal Artillery String Band played during the evening, and short concerts by the "Schartau" part-singers were given at intervals. On Wednesday a large party of the Fellows were shown over the Royal Observatory, Greenwich, by the Astronomer Royal, after which they paid a visit to the Painted Hall and Naval Museum. In the evening a dinner was held at the Westminster Palace Hotel, which was numerously attended, the president being in the chair. The toast of the "Royal Meteorological Society" was proposed by Mr. W. N. Shaw, F.R.S. Gen. Sir H. W. Norman responded for the Army; Prof. Silvanus P. Thompson, F.R.S., for the delegates, and Dr. Pavy for the visitors.

Cambridgeshire Horticultural Society.—This society has been established for about three-quarters of a century, but it still continues a useful work in furthering the interest in horticulture. This year it is holding two exhibitions, the first of which will be held on Tuesday, June 12th, in the gardens of King's College. In addition to upwards of six dozen general classes we find special prizes for Roses, and £22 offered for twelve stove and greenhouse plants. The autumn show takes place in the Corn Exchange on November 7th and 8th, and classes are provided for various plants and flowers as well as Chrysanthemums and fruit. Numerous excellent prizes are offered, and the competition should be good. The honorary secretary is Mr. Arthur Matthew, 20, Trinity Street, Cambridge.

Croydon Chrysanthemum Society.—Croydon has long held a splendid reputation for its Chrysanthemum shows, and so long as the energy and enterprise of the committee and the secretary, Mr. W. Beckett, 272, Portland Road, South Norwood, are continued the status of the society should be maintained. The centre of attraction at the show has been the class for thirty-six Chrysanthemums, in which a challenge cup accompanies the premier prize. This year's exhibition, to be held on October 30th and 31st, should prove no exception, as Frank Lloyd, Esq., is offering a 25-guinea cup for competition, his gardener, Mr. Mills, having permanently annexed the one previously offered. This ought to provoke keen competition, especially as £5, £4, and £3 are given in addition to the cup. The schedule comprises about fifty other classes.

The Reading Gardeners' Association.—The fortnightly meeting of the above association was held on Monday evening last in the Club Room at the Old Abbey Restaurant, when Mr. E. Fry presided over a good attendance of members. The subject of the evening was "Vegetables: the Varieties I Grow, and Why I Grow Them," by Mr. John House, The Gardens, Northlands, Winchester, one of the earliest members of the association. Mr. House, in mentioning the varieties he grew, said that he was greatly handicapped in his selection, as he had to contend with a soil of only 18 inches in depth, and therefore many sorts which Reading gardeners could grow would be utterly unsuitable for his district. An interesting discussion followed. A feature of the meeting was a large and splendid exhibit of flowering bulbs by Mr. F. Lever of The Gardens, Hillside, especially noticeable being Alba Regalis, Vermilion Brilliant, Crimson King, Blanchard, Silver Wing, and Fairy Queen Tulips; King of the Blues, Obolisque, Yellowhammer, and La Belle Hyacinths. A remarkable freak was seen amongst the Tulips, two bulbs in one pot carrying no less than nine blooms. Mr. Cretchley, The Gardens, The Honeys, Twyford, staged a lovely specimen plant of a light-coloured Star Cineraria.

Liverpool National Amateur Gardeners.—A great move is being organised by the president and committee of the above branch to make its influence more far reaching than it has hitherto been. Many new members have been enrolled, and subscriptions obtained freely, so that with such an enthusiast amateur president as Mr. A. W. Ardran and the stirring new secretary, Mr. Macgregor, the branch bids fair to beat all previous records. On Thursday last the Common Hall, Hackins Hey, Liverpool, was crowded with an appreciative audience, amongst whom were noted Mr. R. W. Ker and several professional gardeners. Mr. Duckett Cowan, of the Gateacre Nurseries, lectured on his "Reminiscences of My Travels Collecting Orchids in South America." It was an excellent address, and much appreciated. Afterwards Mr. Ardran admitted having changed his opinion expressed when Mr. Pennington read his paper on "Orchids" last season. At that time he thought the study of Orchids was not a suitable one for an amateur to take up, but thanks to the information gained he was now a most successful grower, and Mr. Cowan's lecture had tended to increase his enthusiasm. Mr. J. H. Drake, another successful amateur, also spoke, and a hearty vote of thanks was proposed to the lecturer. The exhibits were especially good. The following awards were made:—A first prize and certificate to Mr. McMillan for a handsome plant of Dendrobium Wardianum; a second prize to Mr. Drake for a beautiful Odontoglossum Rossi majus on a teak block, and arranged on a small easel; a third to Mr. Ardran. The president's prize for plants in bloom, and certificate, went to Mr. Dale for Cyclamens, whilst Miss Hunter won his prize for cut Orchid blooms. Azaleas were well staged by Mr. J. H. Hoskyn and Mrs. Macgregor. Mr. J. H. Drake exhibited a tasteful Orchid spray. The Mignonette, Genistas, Narcissi, and cut flowers owed their effective arrangement to Miss Hunter, and Messrs. Cangle and McMillan.—R. P. R.

Ancient Society of York Florists.—This society has been doing excellent work amidst the gardening community of the ancient northern city for considerably over a century, and this year at its various shows offers £400 in prizes. Instead of concentrating all their energy on one exhibition, the members of the committee spread it over five, and manage to do the whole of them well. The principal one is fixed for November 14th, 15th, and 16th of this year, and it is hoped the Exhibition Buildings will again be well filled. Groups of Chrysanthemums are a great feature, and receive a considerable amount of attention, but cut flowers, plants, fruits, and vegetables all come in for favourable notice. There are over 100 classes, so that everyone should be able to find room. The secretary, to whom all applications for particulars and schedules must be made, is Mr. Geo. F. W. Oman, 38, Petergate, York.

Grand Yorkshire Gala.—The City of York is always *en fête* on the days of its summer show, and this year should prove no exception. The dates fixed are June 13th, 14th, and 15th; and, as usual, the tents will be fixed in Bootham Field. Mr. C. W. Simmons, The York Hotel, York, continues to officiate as secretary, and will supply all needful information. The enormous amount of £750 is offered in prizes, and is divided somewhat as follows:—£300 for Orchids, stove and greenhouse plants; £200 for Pelargoniums, Carnations, and Begonias; £160 for Roses, cut flowers, &c.; and £90 for fruits and vegetables. New classes have been placed in the schedule for Roses in pots, a table of Orchids, a group of Show Pelargoniums, floral designs, an ornamental stand of flowers and foliage, and a decorated table of ripe fruit. The last is, of course, of the greatest importance, and the prizes will be of the respective values of £15, £12, £8, and £5—£40 in all. The judging will be done by points, of which particulars are given in the schedule.

March Weather at Hodsock Priory, Worksop, Notts.—Mean temperature 38.8°. Maximum in screen 55.6° on the 14th; minimum in screen 24.6° on the 12th. Minimum on grass 12.9° on the 17th. Number frosts in shade thirteen, on grass twenty-seven. Sunshine eighty-seven hours, or 24 per cent. of possible duration. Rainfall 0.65 inch. Difference from average —1.00. Rain fell on eleven days. Rain from January 1st 7.52 inches. Difference from average + 2.41. A dry month, rather dull and cold, with a good deal of N.E. winds and a little snow in the last week.—J. MALLENDER.

March Weather at Belvoir Castle.—The wind was in a northerly direction on twenty-one days. The total rainfall was 0.78 inch; this fell on seventeen days, and is 1.02 inch below the average for the month; the greatest daily fall was 0.23 inch (snow) on the 27th. Barometer (corrected and reduced): Highest reading, 30.665 inches on the 13th at 9 P.M.; lowest reading, 29.237 inches on the 19th at 9 A.M. Thermometers: Highest in the shade, 52° on the 14th; lowest, 23° on the 17th; mean of daily maxima, 43.38°; mean of daily minima, 31.35°; mean temperature of the month, 37.36°; lowest on the grass 13° on the 17th; highest in the sun, 105° on the 14th; mean temperature of the earth at 3 feet, 39.51°. Total sunshine, ninety-five hours twenty minutes, which is six and three-quarter hours below the average for the month. There were nine sunless days. *This has been the coldest March here since 1892.—W. H. DIVERS.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet

For the most part the weather during the past week has been dull and cold, one or two days, however, being quite springlike.

Apple Sturmer Pippin.

I WAS rather astonished to read the depreciatory remarks of "E.," page 271, as to the qualities of this, with me, most acceptable and useful of all the late table Apples. My fruit room is not an ideal one, being too light and airy, but I can manage to keep my Sturmers in fairly good condition until May, in which month they are my best table supply. I send you a fruit or two to try as to flavour, and see the keeping, not that it is necessary to send you Sturmers to prove flavour, because you know what a Sturmer Apple is in all its points as well as anybody, and better than some, but that you may see and taste them again, and in this case fruit of only common orchard production. The trees from which they were gathered are some fifty to sixty years old, and year by year give us good crops of some such Apples as sample sent. Late table Apples are undoubtedly difficult things to keep, Adam's Pearmain for one, but I find that these keep best with me put up in boxes, hampers, or cases, holding say a bushel or so, and kept closely covered until wanted. I felt hurt as well as astonished at "E.'s" charge against my favourite Sturmer Pippin, that I have therefore ventured to send you this.—N. H. P.

[With such excellently flavoured specimens as those you send we can easily understand you appreciate Sturmer Pippin. It is undoubtedly a variety of much merit, but unfortunately has come into disrepute with many other growers besides "E." The reason of this would probably not be easy to find.]

Artificial Manures and Peas.

I OBSERVE that Mr. Udale, in his Worcester C.C. Experimental Garden, found the direct application of a complete chemical manure in the drills with Peas proved harmful. That was my experience many years ago with a similar compound, but when applied direct in the furrows with Potato sets it was very efficacious. Remembering that fact, I last year used so comparatively innocuous a manure as native guano in a trial of it on comparatively poor land with Potatoes only, dressing it in with the sets in the furrows, with capital results, in spite of the drought which followed. No doubt the native guano is quickly soluble, and that being so it gave considerable impetus to the plant growth whilst yet young, which was, in the face of the dryness that followed, a great gain.

In using this manure, however, in other ground and with more crops, the first being with Peas, having one row of a variety manured the other not so, in ten varieties, after ordinary drills had been drawn with a hoe, with a fork I lifted out of each other end, to be the manured row, some 2 inches more of the soil, then strewed in the guano dressing, and followed with a fork, well covering it with soil, so that the seed Peas did not come into contact with the manure. I shall watch the effect of this dressing closely. Judging by the smell emitted this guano is of a free nitrogenous nature, and if it exercises any beneficial influence at all on the Peas it will be chiefly whilst the plants are young.—A. D.

Fruit Prospects.

So far as all fruit trees are concerned it is probable that we have not experienced so late a flowering season for many years, and although the weather answerable for this has arrested growth in all vegetable crops it may help to insure a heavy set of fruit. With the sole exception of Apricots all fruits are looking well, and to use a common expression, "bristling with buds." We have to-day (April 2nd) overhauled our stock of fish netting, and labelled it so that it will be ready to hand when required for the different walls, and mended any gaps with a little tarred twine. For spring protection I have always used a double thickness of half-inch mesh netting, and this has only failed us once in eighteen years, when 24° of frost were registered about the middle of April. Farther north a thicker covering is doubtless necessary, but where the fish netting is sufficient I am convinced there is no better material, for protection is afforded, and at the same time the trees have always the benefit of light and air; the extra work entailed by blinds is also obviated. Sufficient of this netting is kept on hand to cover walls devoted to Peaches and Nectarines, dessert Cherries, cordon Pears and Plums.

It is a fact not generally recognised, but one that deserves attention when taking measures for spring protection, that of the fruits named the Plum is most susceptible to frost; only a slight visitation following an afternoon shower is sufficient to destroy all erect flowers.

Where red spider is locally troublesome it is advisable to look carefully over the walls some warm sunny day before the nets are put on, and if the pest is already in evidence on wood and buds to mix an insecticide to the necessary strength and syringe thoroughly, taking care to miss no part either of the wall or trees. I always find it advisable to adopt such preventive measures, otherwise given a dry time the pests make great headway before the fruit is set. Our cordon Gooseberries on a wire fence are also nearly always attacked, and are syringed with the wall trees.—A. G. B.

The New Chiswick.

I HAVE followed with much interest the remarks that have, from time to time, been made relative to the form in which the Royal Horticultural Society should celebrate its centenary. I may say at the outset that I am in entire agreement with "A Fellow" (page 259) in his views as to the council maintaining its freedom from outside interference. To have an advisory committee, each member of which held differing views, would be worse than useless, and I am wholly in favour of leaving the council unshackled until such time as it can put before the Fellows of the society some definite recommendations. Then, if at all, must Fellows be prepared with other definite schemes for the consideration of the society, for there can be no doubt that the proposed removal of Chiswick is a most serious step that may have considerable influence on the success, or otherwise, of the Royal Horticultural Society.

Personally I am of the opinion that the present garden should be retained to the utmost limit of the lease. Of course we hear much about the soil being exhausted, and the deleterious effects of the atmosphere on the plants that are grown. I should, however, like to ask how much truth there is in either of these statements. That the soil is not what it ought to be cannot be doubted, but is it irremediably bad? As for the atmosphere—well, one can only say that excellent results are secured by various growers in situations equally as bad, and in some cases slightly worse. I am not alone in the opinion that it is more a question of means than otherwise to make the garden a success. No one can gainsay the fact that the superintendent, Mr. S. T. Wright, does remarkably well with the material at command. But is this material the best procurable? I should say that it is not. The labour might be vastly improved, and I venture to assert that few gardeners would care to undertake the management of Chiswick Gardens with the staff as at the present moment. There may be plenty of manure and abundance of water, but there are good and bad methods of employing both.

We hear much about the necessity of the students being *workers*, and we read of it in the official report, but we may be satisfied that not three out of ten answer to this description in reality. Certain it is that when they have an uncongenial task, or have one they are tired of, they have to be moved to something else or they will simply kill time. They do not regard themselves as *workers*, hence the difficulty that the superintendent must face in managing them. That the society does not look upon them as *workers* is proved by the fact that they do not start work until after breakfast, and leave early on Saturdays, whereas the ordinary staff commence and finish at the hours customary in the craft. If they were really in earnest they would recognise the fact that the work done before breakfast in the morning is perhaps the most important in the whole of the gardener's day. How would many gardeners like to have the handling of such a staff as this? There is a tremendous difference in the way that a piece of ground is dug, as every practical cultivator knows, and it is only reasonable to suppose that such work is done by the small regular staff, and not by the young, active, and strong learners. Give the Chiswick manager a full staff of thoroughly good men, and I will undertake to say that the results after two years will be vastly different from those of to-day.

As for the proposed national school of horticulture, I think this is scarcely a thing for the Royal Horticultural or any other society to take up. On the contrary, it is entirely a matter for the State. In other countries we find establishments maintained by the State, but in England, which prides itself on its up-to-dateness, we find matters that are unquestionably of national importance, left either to private individuals or societies. True, we hear of the proposed combination of County Councils, but even this would not be an unmixed blessing, as the more fingers there were in the pie the more wars of words there would be, and consequently the less chance of sound and valuable work being done. No, I should say let the State find the national school of horticulture, and let the Royal Horticultural Society turn its attention first to a suitable place in which to hold its fortnightly shows, and secondly to a new Chiswick if such be necessary. In a single sentence, I think that the Council would do more to meet the approval of Fellows by a proper hall than by half a dozen new Chiswicks and schools of horticulture.—ANOTHER FELLOW.

THE agitation, or rather exceeding anxiety, created in the minds of Fellows of the R.H.S. still continues to manifest itself, and will probably not be allayed until the Council opens its mind to them at general meeting. Whether what is then stated will serve to allay

agitation it is impossible to say, as only members of the Council can know the nature of the negotiations entered upon, or arrangements made, in relation to the new grounds and the talked-of school of horticulture. But whilst many Fellows may think that all this anxiety is a little overdone, no one can for a moment doubt but that it is genuine, and aroused entirely by profound interest in the welfare of the society.

It is, however, worthy of note that whatever may be opinions with respect to what is now being done in obtaining new gardens by the council, that the splendid position the society now occupies has been attained to chiefly by the present administrators, and that fact should do much to establish confidence in them now. Never in all its long history has the society stood higher, had a wider sphere of operations, more Fellows, or done such splendid horticultural work as it is doing at present. That fact needs just now to be impressed upon timid Fellows when they seem disposed to become somewhat hysterical in referring to the action of the council. Now, as a Fellow, I prefer to place some confidence in the wisdom of a governing body that has done so much to place the society in its present eminent position. Of this I feel assured, that in any arrangements now being made in reference to acquiring a new garden or even of assisting in establishing a school of horticulture, that nothing will be done hastily, but that the fullest consideration will be given to every fact. Still further, that in whatever is done, the council will place before all other considerations the advancement of horticulture.—F. R. H. S.

Richardia æthiopica.

THE cultivation of these plants is by no means difficult; they delight in a rich open compost and a liberal supply of water during the season of growth. Their elegant and pleasing appearance admirably adapts them for conservatory and indoor adornment, either in groups or as single specimens. The large white spathes last a considerable time when cut, and are thus extremely useful for decorative purposes, used when possible along with their natural foliage. Arum Lilies (fig. 85) may be had in bloom at a time when flowers are somewhat scarce, and on that account are all the more valuable.

There are two or three different methods of culture. Some cultivators prefer to keep their plants growing continually throughout the year, allowing them no rest whatever during the summer months. In this case the stock should be planted out about 18 inches apart immediately after flowering, in land that has been well manured, giving an abundance of water during dry periods. About the middle of September they must be carefully lifted and repotted with as little injury to the roots as possible, and placed inside out of the reach of frost. This system entails more labour, and gives no better results than when the plants are allowed a rest.

When the plants are to be rested they should be put outside during the first or second week in June in a position where they will obtain all the available sun. Gradually diminish the supply of water until the plants have lost their foliage, when it should be withheld altogether and the pots turned on their sides. About the middle of August they will show signs of fresh growth. They must be repotted before they are very far advanced. Shake away the old soil and rub off all suckers, leaving only one crown to each rhizome. The size of pots required will be governed by the condition of the roots and the purposes for which they are to be employed, pots varying from 7 to 9 inches in diameter being used, with from one to three plants in a pot. When repotting the base of the new growth should be buried about half an inch deep. The compost may consist of three parts of good loam, two parts of decayed manure, adding a little bonemeal and soot, with sufficient sand to keep the whole porous. Stand the plants outside in a shady position, and keep the soil moist by gentle waterings with a rose can.

Towards the end of September it will be necessary to place the plants inside beyond the reach of frost. Any cool house will answer the purpose provided they receive all the light possible, they will then make steady progress without being drawn. As soon as they have got well into growth liquid manure from the cowhouses may be given in limited quantities two or three times a week, with an occasional application of some fertiliser. Soot water is an excellent manure, imparting a deep green colour to the foliage. It does not encourage gross growth, and the presence of ammonia in the house is not so perceptible as from liquid manure from cowsheds. If the plants can be given a temperature of 45° the earliest will commence to bloom about February, and the supply will be continued until the end of May or June.—S. P.

Hardy Annuals.

(Concluded from page 242.)

WHILST providing for a good patch it is advisable not to sow too thickly, though it is better to have to thin than re-sow or transplant. When sown very thickly it is hardly possible to thin the patches without injuring the remaining plants. When the seeds are sown draw the earth over them, covering them no deeper than their own diameter. It is better to cover lightly than deeply, for annuals do not require to be kept or placed in so much darkness as farinaceous seeds. It is sufficient if the seeds are just covered with soil, or kept in the dark, so that the chemical changes which take place in germination may go on. If the ground is dry, it is a good plan to water the patches, and cover them with inverted flower pots, so as to secure uniform moisture in the soil, and obviate the necessity of repeated waterings. The sun's rays, consequently, will not bake or dry the surface, and the inverted pots placed over the patches will absorb heat by day and radiate it at night, so that the seeds will not be roasted at one time and frozen at the other. When the plants appear the pots should be removed, but they may be replaced with advantage on frosty nights, taking care to remove them by the time the soil is thawed.

Where the soil is of a tenacious nature, and at all rough at the time of sowing, it is a good practice to cover the seeds lightly with some light soil, which should be fine, or made so by sifting. Care must be taken in open soils to well pulverise them before sowing the seeds, for it not infrequently happens that the seeds run down the openings, and are lost for that year at least, by being buried too deeply in the soil. Where any danger of this is apprehended, a small portion of sifted mould ought to be placed on the soil for the seed to be sown on. The seeds of some annuals are so small that it is scarcely possible to cover them too thinly, but none will take harm if covered to no greater depth than their own diameter.

When the seedlings are fairly up a ring of dry soot should be placed round each patch to prevent the nocturnal visits of slugs, which will in a single night devour a whole patch. If these pests are troublesome some fresh Cabbage leaves, laid at night near their haunts, and examined in the morning, will collect a great many; and if they be brushed off the leaf into a flower pot, and a little salt sprinkled over them, they will not trouble the cultivator any more. This, repeated for several nights, will soon rid a garden of slugs. Should the weather be dry, the annuals must be watered, and the ground between the patches frequently stirred with a hoe; but a rake cannot be too little used, for the surface ought never to be made fine, so as to throw off rain into the hollows. On the contrary, it should give free access to air and moisture. The aim of the cultivator must be the well-being of his plants, and not that neatness which is secured at the expense of their healthy growth. The longer the soil is kept open the more satisfactory will be the results. When the plants are a few inches high they should be thinned, if too thick. Those which attain to less than a foot in height should be thinned to at least an inch apart, and those growing to a greater height ought to be at least 2 or 3 inches clear of their neighbours. The thinnings may be planted to fill up vacant spaces, or to supply the place of failures. Showery weather is the best for thinning annuals.

As the plants advance in growth care should be taken to stake such as require support, and to place wire trellises for climbers, or sticks for them to cling to, before the one be broken by the winds, or the other spoiled and leggy from creeping on the surface. In dry weather the borders should be well watered, and the surface between the patches frequently stirred to keep down weeds and keep the surface open; and this stirring is best done before the plants feel the effects of drought, or the surface becomes baked or smothered with weeds. It is too late to water annuals when they have become stunted in growth, and surface stirrings after this has taken place are vain. They may indeed improve, but the best plan is to act so that there is little to wish for. When they are in flower they should, if the weather is dry, be well supplied with water. It will much prolong their period of bloom, the flowers will be larger, and the pleasure derived from them will be ten times greater than when they are grown in places altogether unsuited to their proper development.

In sowing annuals due regard must be paid to the habit of each kind and the height to which it attains. Those of trailing and dwarf-growing habit should be sown in front, and the others distributed at such distances from them as their heights may determine. Half the height which any variety grows to is the proper distance to leave between the patches or rows. The tallest should, of course, be sown at the back, and the height gradually diminished towards the front.—PRACTICE.

Fig. 85.—*RICHARDIA* *ÆTHIOPICA*.

Planting Young Vines.

SINCE writing the original article *re stopping Vines* (p. 182, March 1st) I have planted two vineries, each 30 feet in length, lean-to's, facing south. These structures were built, I am informed, by Messrs. J. Weeks and Co. nearly thirty years ago, and are still in a fine state of preservation. The new borders I was obliged to make outside, as considerable expense would have been incurred inside by the removal of three rows of pipes, a cement floor, and a brick wall 3 feet high, which ran parallel with the outer, or the wall which supports the front part of the roof. This inside wall is 18 inches from the outer wall, and both formed a support for a front stage made with huge stone slabs 3 inches thick, since replaced by me with a movable light wooden trellis. This space I have filled with soil, with the intention of planting young Vines next month, which are now being propagated from eyes in the ordinary way. These young Vines will come just between the permanent Vines, that pass through the walls, 4 feet apart, from the outside borders. If these young Vines thrive well I shall crop them next year and the year following, after which they will be cut out, and the Vines in the outside borders will be capable of bearing a fair crop much better than if allowed to carry Grapes the first two years.

The Vines I found in the first vinery were planted when the houses were built, and the drainage was 1 foot in depth on a clay subsoil, over which had been put 3 inches of gravel rammed hard. The second vinery had been twice planted, the last time about ten years ago. Here only 6 inches of drainage had been provided, which was choked with fine soil, and the border consequently quite inferior to that of the early vinery, though it had been made less than half the time. Both vineries had been indifferently managed, and were so full of bug that I decided the safest and most permanent remedy would be to remove the Vines in each house and plant with fresh ones, in the meantime having the houses thoroughly painted and the walls limewashed.

The whole of the soil from the two outside borders, which were 15 feet wide, was carted away, and the drainage cleaned and the bottom freed of all fine soil. As plenty of old whole bricks were at hand drains were formed 8 feet apart with them, from the back to the front. To construct these two rows of bricks were placed edgewise, just far enough apart for a brick, when placed flat, to securely span the two rows, and thus form an admirable drain. If slates had been at command I should have put the bricks on these to prevent worms working soil up and filling the drains, though I do not think they can do so through the clay and gravel bottom. If sufficient 4-inch drain pipes could have been got without expense I should have used these and run them into a main drain. The drainage material consisted of broken bricks a foot in depth, thus covering the drains. This gave a depth of 2 feet 9 from the drainage to the front sill of the window sashes. The drainage was covered with turves, placed grass side downwards, but previous to this I put two 12-inch boards edgewise on top of each other, with stakes driven in each side of them to keep them in position. This method is, I think, preferable to a turf wall for keeping up the soil the whole length at the front of the borders. These borders were made 9 feet wide, so that no expense would be incurred by renewing in a couple of years' time, though probably a width of 6 feet would have been ample for two years at least.

Now, a few remarks as to the soil used will, I think, not be without interest to Journal readers, though in all probability the compost will not suit the tastes of all Grape growers; but in this case I hope they will criticise soundly and practically for the mutual benefit of myself and other readers. The soil round this part of Essex is far from my ideal of a good Grape producing loam; but I had no alternative to using that close at hand from a pasture laid down about fifteen years ago, and on which no manure had ever been carted to the recollection of some old hands. The turf was ploughed to the depth of 2½ inches, and forty loads of about one square yard each carted to a spot close to the vineries. This soil was roughly chopped up and put ridge shape as the work proceeded to facilitate its being easily covered to keep off the rain. To the forty loads of soil were added eighty wheelbarrowfuls of mortar rubbish, forty of burnt garden refuse, also thirty bushels of 3-inch charcoal, and one ton of Bentley's Vine border compound, which is apparently largely composed of half-inch bones, hoofs and horns. The whole heap was carefully mixed. Four wheelbarrows were used in taking it to the place where the border was to be made, and by filling them from both ends of the heap, and shovelling the compost out of the barrows, working backwards and forwards, the whole length of the borders, it was equally distributed. As the second vinery will contain mostly Muscats, 3 bushels of charcoal were reserved and added to this border as the work of filling proceeded. Each layer of soil was made firm, and there was the exact quantity for filling the two borders—viz., 60 feet by 9 feet, to a depth of 2 feet 3 inches—thus allowing 6 inches for top-dressing near the Vines, and more at the front, as the border was sloped somewhat.

The Vines were purchased in pots in November, and pruned the first week in December to within 3 feet of the base, but although kept cool the young canes bled profusely. After trying various remedies to stay this loss of sap without success, I procured some painters'

knotting, which, after three applications, checked and finally stopped it. This knotting seemed to securely seal the pores of the wood. The first week in this month the Vines were shaken out of the soil in the pots, and the roots carefully disposed in the new borders, and the shortened canes passed through small openings 4 feet apart in the brick wall, and tied to the first wire inside the house. The buds on these young canes are now swelling; those at the top part will be rubbed off as they attain 1 inch in length, and a bud on each cane will be selected that just reaches the top of the inside front stage, or, in other words, 18 inches from the base. This method answers my case admirably. It would have been folly to have pruned the young canes to within two eyes of the base, as the young growth would have been made in partial darkness. The Vines would have been planted earlier had the weather permitted.—A. J., *Moor Hall*.

Auriculas.

THE meeting of the Royal Horticultural Society at the Drill Hall on April 24th will be associated with the annual show of the National Auricula Society in the South, and is naturally being looked for by lovers of spring flowers with much interest, because that charming family of plants Primulaceæ is invariably widely represented at the meeting. Primarily the chief attraction will be found in the Auriculas. It does not say very much for the labours of the society that for the past two years the show has not exhibited the high quality seen some years since in its Auriculas. That the shows have lost much in the absence of some northern growers there can be no doubt, and it is equally certain that in the varieties of Auriculas staged there is no advance in quality also.

Practically the Show Auricula stands still. It seems incapable of improvement or development. Certainly a perfect flower as seen in the best varieties is the most remarkable of all floral combinations that florists have created, but the power of the florist seems incapable of further expansion. Then the Show Auricula is too much the creature of artificial production. Probably at the present moment of writing hardly an intending exhibitor but has his plants in warmth, for Nature is slow this season, and plants in cold frames or houses will not bloom until some time later, and plants outdoors, where the Auricula seems to be most at home, will be nearly a month later to bloom.

The beautiful varieties classed as border Auriculas, however, and which flower so profusely and for many years outdoors, have no attraction for the exhibiting grower of Auriculas. His plants, indeed, hardy as they presumably are, would make almost as poor a show outdoors as Cinerarias or Chinese Primulas. They need much protection sometimes, as now, some warmth, and not a little coddling. Of all plants grown to give pleasure that produce flowers, few give less show in the way of bloom than do Auriculas; indeed a year's constant attention and careful culture seem poorly repaid by some three weeks of bloom. One reason for this short period of florescence is found in the practice of reducing the flower stem to one generally on a plant, and in thinning down the pips to quite a few, that when the plants are presented for exhibition the whole of the few pips forming the truss may be open at the same time.

In the case of Alpines—and these seem to present greater general attractions to the public than do the choicer and even more delicate Shows—more than one truss of bloom is permissible; but even with these late buds are usually removed, that each truss may seem alike in development. With so much that is quite artificial, in association with what is a beautiful and naturally very hardy flower, it does seem a pity that the National Society should do nothing to encourage the hardy border varieties, which do so much in May when well grown to make gardens attractive. A few prizes offered for these in pots would be useful, but in such case, to be in bloom so early as the 24th of April, they too would have to be pushed on in gentle warmth.

For that reason it would be so much better could a couple of classes be established for hardy border varieties in pots, not exceeding 6 inches in diameter, for the first meeting in May, as by that time most of the plants might be in bloom, or would need very little assistance to get them into flower. It seems probable that border Polyanthus will not be seen at their best this year so early as the 24th, for these never look better or fresher than when lifted from the open ground direct into pots and brought to the show. Few plants suffer more or become drawn and out of character or colour and freshness when put into warmth under glass than these Polyanthus do. Hence it is that so many of the plants seen at the Drill Hall look poor and drawn when compared with outdoors stock.—A. D.

A NEW PARK FOR PHILADELPHIA.—It is largely owing to the exertions of Mr. Thomas Meehan that the City of Philadelphia has secured the dwelling and part of the grounds that belonged to James Logan, who, with William Penn, founded the State of Pennsylvania. The estate will be known as Stenton Park.

Corylopsis.—A common failing among many of the earliest of our shrubs is their inability to withstand a sharp night's frost when in flower. The subject of this note is among the number of genera which exhibit this shortcoming; yet when a plant of either of the species is seen at its best it commands a large amount of attention. To be sure of saving the flowers a few plants should be lifted and put in a cool house or frame from which frost is excluded. Early in March they will commence to flower and form most useful plants for decoration of room or conservatory. There are several species, but two only can be obtained in quantity. Those are *C. pauciflora* and *C. spicata*. The first named is a good example of bad naming, as it is one of the most profuse flowering plants imaginable. The flowers are primrose yellow and borne in drooping catkins of two or three flowers, each from every bud on the previous year's wood. Altogether it makes a charming picture. *C. spicata* is a stronger, stiffer growing plant, bearing catkins, often 3 inches long, of yellow flowers with prominent red anthers. Both are Japanese plants.—W. D.

Sphaeralcea abutiloides.—There are large numbers of very beautiful flowering plants included in the *Malva* family which are well known in gardens; the one under notice, however, is seldom seen. It is a native of the Bahamas, and is one of the oldest of our indoor exotic plants, having been introduced nearly two centuries ago. If left alone it makes a tall, straggling plant, with a few leaves, the branches being terminated by large heads of flowers. If, however, when young, it is kept well pinched, four or five good shoots may be had which will each bear a large quantity of blossom. The leaves are very like those of the *Abutilon* in shape, but are whitish, through the presence of a large quantity of downy hairs. The flowers are rose-coloured, 1 to 1½ inch across, and produced several together on fairly long stalks from each leaf axil near the apex of the shoot. Its usual flowering period is summer, but by starting late in the spring and keeping well stopped, it may be had in flower in March, a time when indoor flowers are more appreciated. Capital little pot plants 9 inches high bearing large quantities of flowers may be had by rooting cuttings in July and growing them in 4 or 5-inch pots through the winter. An intermediate temperature, and a compost similar to that used for *Abutilons*, will suit its requirements.—R. G. K.

"The Flora of Mount Kosciusko,"—Such was the title of a lecture given in Sydney by Mr. J. H. Maiden, Director of the Botanic Gardens of that city. The highest mountain in Australia does not boast of flowers which may be termed showy, but many of them possess a beauty and a sweetness particularly their own, so that it did not seem an exaggeration to call them gems. Vegetation on the mountain ceased at an altitude of 6500 feet. For some distance only one kind of tree was seen, the Snow Gum (*Eucalyptus coriacea*), and it gradually diminished in size. Above were wind-swept plains, plentifully bestrewn with dwarf shrubs and tiny herbs. These plains are dotted over with granite masses, in the interstices of which a number of interesting plants thrived in addition to those found in the more open country. By far the greater number of the flowers were white in colour, yellow ranking next. There was only one plant bearing a blue flower—namely, *Dianella tasmanica*. Red flowers seem to be entirely absent from the plains. That was different from what obtained in the Alps of Europe, where flowers of many colours were represented in a space little more extensive than a hand's breadth. Not many plants on Kosciusko exhaled perfumes. Excluding the few *Rutaceæ* and *Myrtaceæ*, whose leaves only emitted an odour when crushed, the notable perfumes appeared to be confined to the genera *Epacris* and *Stackhousia*. Some specimens of the former on the mountain exhaled a most powerful odour of cloves, which was observed at long distances from the blossoms. A powerful and sweet perfume was emitted from the little mats formed by the *Stackhousia pulvinaris*, a yellow flowering plant. Many of the plants exhibited a dwarfing in size. Less than half a dozen Ferns were found. There were no epiphytal Orchids, and only few terrestrial ones. A number of the plant-gems should be transferred to the rockeries and other places in the colder parts of the colony.—("Indian Gardening.")

Gardeners in the Olden Time.—The following may be interesting, as illustrative of the manners of the gardeners of the olden time. In 1345 (19 Edw. III.) "the gardeners of the earls, barons, and bishops, and of the citizens of the city of London" petitioned the mayor, John Hammond, that they might "stand in peace in the same place where they had been wont in times of old, in front of the church of St. Austin, at the side of the gate of St. Paul's Churchyard, there to sell the garden produce of their said masters, and make their profit." But the mayor, finding that "the scurrility, clamour, and nuisance of the gardeners and their servants there selling pods, Cherries, vegetables, and other wares to their trade pertaining daily, disturbed" the priests in the church of St. Austin, as well as the reputable inhabitants, ordered that henceforth the gardeners "should have as their place, the space between the south gate of the churchyard of the said church and the garden wall of the Friars Preachers (Black Friars) at Baynard's Castle."

Garden Edgings.—The mention of old gas piping, in the note on page 298, as posts for wire fencing, reminds me of another way in which it can be utilised, and where it proves very neat and serviceable—namely, as an edging to garden paths. When I took my present charge some eighteen years ago the Box edging in the kitchen garden was in such a state as to be practically useless. Tiles were first suggested as a substitute, but as the time of fixing, labour, and cost of material were all considered, and there were something over 1200 yards to be done, I decided to employ old 1-inch gas piping, of which a considerable amount could be purchased cheaply, and which could be fixed in quite one-twentieth the time. The ground having been levelled and made firm, the lengths were laid in position, joined together by round blocks of wood inserted in the ends, and the whole made firm with neat iron staples driven in at intervals, made flat at the top, and with round sides sufficiently long to get a firm grip.—A. G. B.

Rhododendron Shilsoni.—A large specimen of this was presented to Kew in 1898 by the raiser, D. H. Shilson, Esq., of Tremough, Cornwall, and is now flowering grandly in the Himalayan house. A hybrid between two of the showiest Himalayan species, *R. Thomsoni* and *R. barbatum*, it inherits good qualities from both. The Kew plant is 9 feet high, by the same in diameter. The leaves are about the same in size and colour as those of *R. Thomsoni*, but have not the blunt apex of that species, inclining rather to the more pointed termination of *R. barbatum*. The flowers are blood red, and borne twelve to eighteen together in the conical compact truss of *barbatum*. In size they are much larger than those of *R. barbatum*, and possess the waxy texture of *R. Thomsoni*. The chief defect of the plant is its earliness of flowering, for although perfectly hardy, the flowers are apt to be injured by late spring frosts in the more northern counties. In the south-west of England it is considered one of the very best of outdoor hybrids.—KEWITE.

Early Seed Sowing.—I have often met with gardeners, though chiefly of the amateur element, who like to boast that they have sown seeds, planted Potatoes, and done many things a month before sensible practical gardeners would do so. That may seem odd cause for boasting, but the weaknesses of human nature descend even so low as that. It is just possible that the present season, I can hardly term it "spring" yet, will serve to open the eyes of some who want teaching as to the worthlessness of such early sowing, whilst soil is cold, and possibly wet, the sky is sunless, and the air cold and cheerless. As between sowing seeds in March and April, there can be no doubt but that in securing better germination and quicker and more robust growth the latter month has the advantage. I have heard this season so many remarks as to the long time seeds have taken to germinate. The fault does not lie in the seeds, for last year's produce was of the very best. It lies rather in the committal of the seeds to soil that is yet so incapable of promoting growth, and with an atmospheric temperature that is wintery in character. The hardiest and earliest of seeds to make growth in the spring time are those of weeds, yet I have not seen growth on these yet. Early sowing has been aided no doubt by the admirable condition of the soil generally for their reception except on stiff clays, and thus many persons have been tempted to sow too early. A few mild open days in March naturally tempt men to get in many crops, but almost ere committed to earth cold again returns with sharp frosts at night, and possibly keen north or east winds, hence the early sowing finds no gain. Happy are those gardeners who have plenty of movable frames at their disposal, as then so many things can be raised quickly that would, in the ground outside, simply linger in the soil or perhaps die.—A. D.

Subtropical Bedding.

IN addition to the plants already enumerated in my previous notes (page 290), there are many perennial ones which are indispensable when the work is carried out on a large scale, as lofty Palms and Tree Ferns, towering above other plants of bold appearance, are needed to give a truly tropical effect. It is, however, only in public parks or large gardens that this noble style of bedding can be carried out in a thoroughly comprehensive way, for a great amount of space is needed to show off prominent specimens to advantage, and give due proportion to the whole arrangement.

Unfortunately the majority of the lofty plants suitable for the purpose need the protection of a greenhouse during six months of the year, and are therefore not within the reach of those who have no structures of sufficient size to winter them in. In such instances good use should be made of plants which are hardy. One of the most striking for the purpose is the Great Reed (*Arundo Donax*). If planted in deep rich soil it will produce strong reeds from 6 to 10 feet in height during one season. A plant of it forms a capital centre for a large circular bed, to be filled in with Cannas, Castor Oil plants, or Zeas; a broad edging of Beet, or the golden-leaved *Funkia*, gives an excellent finish to the arrangement. There are several species and varieties of *Funkias* which are perfectly hardy, and are invaluable for massing in beds or employing as edgings, as they have such bold foliage, and range in height from 6 inches to 2 feet.

Many of the Bamboos are also quite hardy, and are admirably adapted for planting to form clumps in isolated positions. Let us suppose that a series of beds or borders are arranged on grass with ample space between them, for tall striking plants. Such are ideal positions for Bamboos. Stake out a few sites at well chosen points, dig holes 4 feet in width and 3 in depth, obtain good turfy loam enriched with manure, and plant the following kinds: *B. aurea*, *B. Fortunei*, *B. mitis*, *B. nigra*, and *B. Simoni*. These will in time grow into beautiful specimens, increasing in size and height each year. As the plants throw up suckers, some of them should be removed annually to keep the plants within due bounds, and the turf must be kept clear of the main tuft and stems, to allow them to be dressed with manure annually and watered during hot weather in summertime. Two fine Bamboos for growing in pots and placing in the open air in June are *B. nana* and *B. arundinacea*.

The Pampas Grasses are also excellent hardy plants for the centre of beds, or for disposing isolated specimens on grass; in a few years they grow into wonderfully fine clumps, and their graceful foliage and feathery plumes contrast well with the many bold leaved plants used in the subtropical garden. A bed formed principally of *Azaleas* makes a striking feature, and although the plants need protection in winter, if sufficient space in a greenhouse is not at command they may be kept with safety in frostproof sheds. In my younger days I served in a garden where plants 5 or 6 feet in height were for years wintered in a shed. Some of the best varieties are *A. americana* (green leaved), *A. americana variegata*, *A. americana mexicana*, *A. Celsiana*, and *A. densiflora*. When arranging them in their summer quarters, plunge the pots in the soil of the bed, have plants of various sizes, place the larger ones at wide intervals apart, and the smaller ones here and there between, so as to form an irregular surface. *Echeveria metallica*, or *E. secunda glauca*, makes a capital edging, and *Sedum acre aurum*, if used as a groundwork for the whole arrangement, gives an excellent finishing touch. Old clumps pulled to pieces and dibbled in 2 inches apart soon grow into a compact carpet.

Those who have room to winter tall plants should grow the following—*Chamaerops humilis*, *Livistona australis*, *Dracaena Veitchii*, *Phoenix dactylifera*, *Trachycarpus excelsus*, *Musa ensata*, *M. superba*, *Cycas circinalis*, and those two fine Tree Ferns, *Alsophila australis* and *Dicksonia antarctica*. All these plants should be plunged in their pots or tubs, and be kept regularly watered. When they are disposed on lawns it is an easy matter to roll back the turf, and after plunging the pots relay the turf to within a few inches of the stems of the plants. They then look perfectly natural, and room is left for giving water. In planning out bedding of the above description advantage should be taken of any special features the garden possesses, as beds arranged near rockwork or water are particularly effective. Some shelter from strong winds, if possible, ought to be secured, as the limbs of many of the plants used are easily injured during gales. In all instances rapid growing plants should be secured to strong stakes.

Undulating ground, where it is backed up by trees or shrubberies, may by the expenditure of a little labour and ingenuity be converted into an ideal position for subtropical bedding, for when associated with winding walks, irregular borders, and grassy mounds, bold and varied plants have their characteristics more clearly defined.—H. D.

Potentilla fruticosa.

THIS is a very distinct form of *Potentilla*, as it departs from the usual low rambling or creeping types of the genus in its shrubby habit. On rockeries it succeeds admirably, forming compact little bushes from 1 to 2 feet high, covered with its neat bright yellow flowers (fig. 86), which are produced in great numbers throughout the summer months. It is occasionally found in mountainous districts of Great Britain, but is not common; and it is also found in various parts of Europe, especially in the Pyrenees. In well drained borders it grows strongly, but much the best position is the rockery, on which it is soon established, and can readily be increased by division or by seeds. *P. fruticosa* is also found in various parts of Asia, and even in America. In the latter country, however, several shrubby forms have been noted, which by some botanists have been regarded as varieties of this one, and by others as distinct species. Examples of these are found in *P. floribunda*, a North American plant; *P. parvifolia*, from the Soongarian Desert; *P. dahurica*, from Dahuria; *P. arbuscula*, *P. rigida*, *P. lignosa*, and *P. Salesovi*. The last named is somewhat of the habit of *P. fruticosa*, but is easily recognised in the leaves of *P. Salesovi* not having the same silvery appearance, and the leaflets are more sharply serrated.

An Hour at Williams'.

THE horticultural world in general, and London in particular, has seen many changes during the past half-century, and amongst the participators in all the various phases have been Messrs. B. S. Williams and Son, of Upper Holloway. From the time when the late Mr. Benjamin Williams was doing such meritorious work for horticulture, and was laying the foundation of an excellent business, until to-day, the firm has ever been to the fore. Now, under the personal direction of Mr. Henry Williams, the business in its several aspects continues its prosperity, though the lines adopted may be and probably are vastly different from those of long ago. Plants that a quarter of a century back made the name of the Victoria and Paradise Nurseries more than famous, have had to go to the wall, for fickle fashion has exalted other favourites, which will, in their turn, have perforce to languish in a practically forgotten obscurity.

Not only have men and manners altered, but establishments also have felt the touch of time. London has grown and is growing, and with its constantly widening boundaries the smoke fiend has travelled. In situations where awhile ago it was easy to grow almost any plant, it has become an almost disheartening task, for after all the skilful care many only just exist. Having this unfortunately ever increasing difficulty to contend with, the fact was forced upon Messrs. Williams and Son that if they wished to maintain their prestige they must go further afield beyond the pernicious influences of the smoke and fog. With this end in view a considerable area of ground was acquired at Finchley, where, in addition to glass structures, there was ample space for Roses, shrubs, and other hardy stock. This ought to prove a most admirable arrangement, as all kinds of plants grown there can be drawn upon for the supply of the principal establishment. A small portion of the lower portion of the home nursery has passed into the hands of the builder, but the main frontage and a large majority of the houses remain intact.

A few days ago the houses at Holloway were inspected, and it is really surprising what immense numbers of plants are accommodated in the space at command. Furnishing is a great specialty of the firm, and to meet the demands of this department alone thousands of Palms of various kinds are essential. Hence we find the large conservatory and more than one house completely filled with plants ranging from a few inches to many feet in height. Kentias by the thousand are raised at home, and, despite the space that is accorded to them, the supply is rarely or never equal to the demand. Some of the plants show signs of having had a spell in some uncongenial atmosphere, but, as a rule, they are clean, healthy, and of good shape—in fact, perfectly adapted for furnishing purposes.

The collection of Orchids is more extensive than one might suppose at first glance, and the condition of the plants reflects undeniable credit on the growers. They may not have the ruddy glow of health in the leafage that one would look for in a purely rural neighbourhood, but they, notwithstanding smoke and bad light, look hardy in the growth and firm in the bulb. Such plants as these could scarcely fail to make markedly good progress when they were taken to more suitable places in a clear growing atmosphere. Several houses are devoted to them, but it is seldom that many plants can be found in flower, as the firm's floral depôt in Piccadilly swallows up all that can possibly be supplied. This may detract somewhat from the appearance of the houses, but it is a good sign of activity in one phase of the business, and, moreover, it relieves the plants from the burden of carrying the flower spikes too

long. There are large numbers of *Laelias*, *Cattleyas*, *Cypripediums*, *Odontoglossums*, and many others in various stages of growth, some of which have proved their worth, while others have not yet had time to produce any flowers. A collection of *Laelia purpurata* was in splendid form, and the plants were throwing up large numbers of sheaths. It may be presumed that the Orchids will eventually find their way to Finchley.

For furnishing, as well as for the supply of the West End shop, forced shrubs are a necessity, and one finds that they are very largely grown. *Clivias*, or to call them by the older and decidedly longer name of *Imantophyllums*, find a certain amount of favour, but, like the *Amaryllis*, their glory, so far as the Victoria and Paradise Nurseries are concerned, has departed. At the same time, some handsomely coloured flowers of varying forms of *Clivia miniata* were noted in passing. Of the general stock of hardwooded and other plants it would be impossible, within the brief scope of such an article as this, to speak, and they must, therefore, be passed without comment. Naturally enough, in a nursery like this, to name the whole of the plants would be an almost endless task, and we will, therefore, leave it for other opportunities as they arrive in the future.—F. W. H.

The Royal Horticultural Society.

Drill Hall, April 10th.

The exhibition in the Drill Hall on Tuesday was one of the most attractive we have seen of late. Neither Orchids nor fruits were particularly numerous, but floral exhibits were abundant and of excellent quality and variety. Narcissi, owing to the lateness of the season, were less numerous than might have been expected, but these will probably be very plentiful a fortnight hence.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); the Rev. W. Wilks, and Messrs. J. Cheal, A. F. Barron, E. S. Blaker, A. H. Pearson, A. Dean, S. Mortimer, H. Markham, J. W. Bates, W. Farr, G. Woodward, G. Wythes, F. Q. Lane, J. Smith, E. Beckett, G. Bunvard, and W. Gleeson.

Messrs. J. Cheal & Sons, Crawley, staged sixty dishes of Apples in good condition. The most striking were Wellington, Chelmsford Wonder, Newton Wonder (excellent), Lane's Prince Albert, Bess Pool, Sandringham, London Pippin, Adam's Pearmain, and High Canons. Mr. J. May, gardener to J. B. Joel, Esq., Potter's Bar, staged two baskets of Potato Syon House Prolific, which were even in size and in good condition. Mr. Geo. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, sent a box of Royal Sovereign Strawberry in capital condition.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. C. T. Druery, H. B. May, R. Dean, R. B. Lowe, W. Bain, J. D. Pawle, C. E. Pearson, G. Gordon, C. E. Shea, E. H. Jenkins, H. J. Cutbush, W. J. James, H. Turner, G. Paul, E. T. Cook, J. W. Barr, J. Fraser, and E. Mawley.

Messrs. H. Cannell & Sons, Swanley, staged a wonderful display of single Zonal Pelargoniums tastefully embedded in a bank of Maidenhair Fern. The exhibit was unique, for it is seldom that even the Swanley firm brings out an exhibit at this season, and, needless to say, they were grown in Mr. Cannell's well known style. The best varieties were Mrs. Hall, Lord Reay, Mrs. Simpson, Soldier's Tunic, Souvenir de W. B. Miller, Nicholas II., Chaucer, W. E. Corden, Menelik, and Crabbe. Messrs. J. Hill & Son, Barrowfield Nurseries, Lower Edmonton, arranged a large table of tinted and variegated Ferns, chiefly in small pots, massed in baskets; needless to say they were most effective. The most striking were *Blechnum occidentale*, *Pteris tricolor*, *Doodia aspera multifida*, *Athyrium Goringianum pictum*, and *Adiantums Legrandi*, *Collisi*, and *scutum roseum*; it was certainly an interesting exhibit.

Messrs. W. Paul & Son, Waltham Cross, arranged a large display of spring flowering plants in pots. The Camellias formed the chief feature, but no less pleasing were the other plants, such as *Forsythia suspensa*, *Pyrus malus floribunda Scheideckeri*, *Cytisus scoparius præcox*, *Staphylea colchica*, and *Laburnums*. The Camellias were in splendid condition, and the chief forms, such as *fimbriata*, *conspicua*, *Madonna*, *Commendatore Betts*, *Pride of Waltham*, and *C. H. Hovey* were especially noteworthy, while a number of boxes containing much the same varieties made a pretty front to the exhibit. Messrs. R. & G. Cuthbert, Southgate, arranged a handsome table of *Azalea mollis* in great variety, also well flowered plants of *Staphylea colchica* and *Magnolia conspicua* arranged with Palms and edging of *Pteris Wimsetti*. The best *Azaleas* were *Comte de Comer*, *Queen Sophia*, *Alphonse Levallee*, *Consul Pecher*, *Anthony Koster*, and *Mr. L. J. Endtz*.

Messrs. R. Wallace & Co., Colchester, staged a few choice spring flowers, consisting of *Irises assyriaca* and *I. stylosa speciosa*, *Erythronium Hendersoni*, the curious *Tulipa Kaufmanniana*, and *Fritillaria aurea* var. and *F. pudica*. Messrs. W. Cutbush & Sons, Highgate, also contributed a beautiful and odoriferous exhibit, in which the *Ericas* were chiefly noteworthy. The collection included charming decorative plants of *Erica Wilmoreana*, *E. persoluta alba*, *E. coccinea minor*, *E. Cavendishi*, and *E. candidissima*; also *Epacris*, *Boronia mega-*

stigma, *Acacia Drummondii*, *Magnolia Lenné*, *Lilacs*, and the beautiful *Cytisus Andreana*, arranged with Ferns and Palms. Mr. G. W. Piper, Uckfield, exhibited two bamboo stands full of Sunrise Roses. This variety is now well known and needs no description. The buds were beautifully coloured and fresh.

Messrs. F. Cant & Co., Braiswick Nursery, Colchester, staged boxes of superb Roses, chiefly Teas, in capital condition. The blooms were large, fresh, and bright in colour. The best Teas were *Madame Hoste*, *Medea*, *Ethol Brownlow*, *Cleopatra*, *Innoconte Pirola*, *Madame de Wattville*, and *Souvenir de Catherine Guillot*; while the Hybrid Teas included good flowers of *Danmark*, *Rainbow*, *Carolino Testout*, and *Marquis Litta*, with a few Hybrid Perpetuals; the flowers were well arranged, and the exhibits worthy of Colchester. Mr. Geo. Mount, Canterbury, staged a beautiful exhibit of Roses, which included boxes of blooms staged in the orthodox style, and a quantity arranged in vases with long stalks, most handsome in appearance. The boxes

FIG. 86.—POTENTILLA FRUTICOSA.

contained good examples of *Prince Arthur*, *Mrs. W. J. Grant*, *Bridesmaid*, excellent *Catherine Mermet*, *Captain Hayward*, *Mrs. John Laing*, and *Niphetos*.

A collection of *Azalea mollis*, chiefly seedlings in various shades of yellow, were staged by Mr. J. Russell, Richmond Nurseries, Richmond; the plants were full of bloom and naturally attractive. The same firm also contributed a group of hardy flowering shrubs, such as *Viburnum opulus*, *Rhododendron Cunningham's White*, *Laburnums*, and *Andromeda speciosa*—an effective exhibit. A large table of cut *Rhododendron* blooms came from Mr. R. Gill, gardener to D. H. Shilson, Esq., Tromough Gardens, Penryn, Cornwall, all grown in the open air; such a display makes one long for our own spring to appear. The varieties chiefly to be noted were *R. Edgworthi*, *R. Shilsoni*, *barbatum*, and a large variety of good seedlings. The display was much appreciated by the visitors.

Messrs. B. S. Williams & Son, Holloway, arranged a fine group of spring flowering plants in pots, also foliage plants, the double Thorns, *Lilacs* in variety, the old *Kerria japonica*, *Spiræa confusa*, and a pretty collection of *Azalea mollis*, arranged with *Acers* in variety. The whole formed one of the most effective displays seen for some time at the Hall. Messrs. Paul & Son, Cheshunt, had the privilege of staging their exhibit in a very bad light, which effectually destroyed its beauty. The Roses included plants of *Paul's Carmine Pillar*, *Miss Ellen Willmott*, *Madame E. Cauvin*, and *Madame Berkeley*, a few good seedling *Hippeastrums*, and some pretty rock plants, such as *Hepatica angulosa*, *Aubrietia purpurea*, *Saxifraga atropurpurea*, and *Sisyrinchium grandiflorum album* in pans were pretty.

An interesting table of alpine plants was staged by Mr. P. Purnell, Woodlands, Streatham Hill. The Primulas, Scillas, Gentianas, and Ericas provided the flowering plants, while Sempervivums in variety were equally interesting and varied. Messrs. J. Peed & Son, Roupell Park Nurseries, West Norwood, staged a semicircular group of Clivias, with a few other spring flowering plants, edged with *Pteris cristata*.

Messrs. Barr & Sons, Covent Garden, made a bright display with Daffodils effectively arranged on one of the side tables. Such varieties as Horsefieldi, Madame de Graaff, Grandis, Mrs. Langtry, Gloria Mundi, Glory of Leiden, Ellen Barr, and Mrs. Walter Ware, were tastefully set up in glasses, and other varieties were represented in pots. The same firm also showed flowers of *N. Poetaz*, a cross between *N. Poeticus* and *N. Tazetta*. Mrs. Kendall, Newton Poppleford, Devon, showed flowers of the beautiful *Narcissus King Alfred*, which was granted a F.C.C. in 1899. Messrs. G. Jackman & Son, Woking, sent a collection of Daffodils and other hardy flowers; Emperor, Golden Spur, Sir Watkin, Maximus, and Henry Irving were conspicuous among the former. Very effective was the Irish exhibit of Daffodils sent by Miss Curry, The Mall House, Lismore. A large number of varieties were represented, including Marchioness of Lorne, Autocrat, Victoria, Scoticus, Thomas Moore, John Bain, Sir Watkin, Horsefieldi, Princess Ida, Edward Hart, and Emperor (the Barr silver cup).

ORCHID COMMITTEE.—Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. J. O'Brien, de B. Crawshay, H. Ballantine, H. Little, F. Sander, J. T. Gabriel, H. J. Chapman, H. A. Tracy, W. H. White, J. Jaques, E. Hill, J. Coleman, R. B. White, C. J. Lucas, W. H. Young, H. T. Pitt, and Jas. Douglas.

Messrs. F. Sander & Co., St. Albans, contributed a small group of Orchids, in which *Dendrobium Phalaenopsis Schröderianum*, *D. lituifolium*, *Miltonia vexillaria*, *Odontoglossums* and *Cattleyas* were conspicuous. De Barri Crawshay, Esq., Sevenoaks, exhibited a number of *Odontoglossums*, including forms of *crispum* *Andersonianum*, *Rossi*, and others. Mr. C. Kench, gardener to J. S. Moss, Esq., Bishop's Waltham, showed a good form of *Odontoglossum crispum*. Mr. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill, arranged a small group of Orchids. There were *Cattleyas*, *Odontoglossums*, and others in fine variety.

Mr. W. H. Young, Orchid grower to Sir Frederic Wigan, Bart., Clare Lawn, East Sheen, staged a beautiful collection of Orchids. *Dendrobiums* were very handsome, as were *Cattleya Schröderæ*, *Phalaenopsis Sanderiana*, *Lælia Olivia*, *Odontoglossums*, *Cypripediums*, and *Epidendrum Stamfordianum*. Messrs. J. Veitch & Sons, Ltd., Chelsea, exhibited *Lælia Digbyano-purpurata fimbriata*; *Epidendrum Clarissa*, *Dendrobium Cordelia album*, *Cattleya Eros*, *C. Rosalind superba*, *Cypripedium J. Gurney Fowler*, *Dendrobium Wardianum japonicum*, and *D. Sosius*, a handsome hybrid from *D. nobile* and *D. splendidissimum*.

Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, staged *Dendrobium aureo-Wardianum*, *D. superbum Huttoni*, *D. superbum*, *D. nobile Murrhinianum*, *D. Rolfeæ*, *Polystachya laxiflora*, *Lælia flava Cowani*, and others. A few other Orchids were contributed in smaller numbers by various growers.

MEDALS.—*Floral Committee*.—Silver Flora medals to Messrs. H. Cannell & Sons, R. & G. Cuthbert, B. S. Williams & Son; silver-gilt Flora medals to Messrs. H. Shilson and G. Mount; silver-gilt Banksian medals to Messrs. W. Paul & Son and F. Cant & Co.; silver Banksian medals to Messrs. P. Purnell, J. Hill & Son, and J. Russell. *Fruit Committee*.—Silver Knightian medal to Messrs. J. Cheal & Sons. *Narcissus Committee*.—Silver Flora medal to Messrs. Barr & Sons. *Orchid Committee*.—Silver Flora medals to Messrs. H. T. Pitt and W. H. Young.

Certificates and Awards of Merit.

Amaryllis Titan (J. Veitch & Sons).—A handsomely formed flower; the colour is pure white, with crimson rose on the upper segments (award of merit).

Amaryllis Zephyr (J. Veitch & Sons).—The colour of this is bright scarlet, with white on the margins (award of merit).

Azalea Mrs. A. E. Endtz (R. & G. Cuthbert).—This is a superb form of *mollis*; the flowers are a peculiarly rich orange yellow (award of merit).

Azalea Duchess of Wellington (R. & G. Cuthbert).—A very attractive Ghent variety. The colour is pale blush, with bright red on the upper portion of the flower (award of merit).

Azalea Madame de Smet (Paul & Son).—This is almost a white, with yellow on the upper portion (award of merit).

Batemannia Burti, *Pitts* var. (H. T. Pitt).—A superb form with varnished green tips to the white organs (first-class certificate).

Cattleya Rosalind superba (J. Veitch & Sons).—A beautiful variety. The sepals and petals are rose, and the lip rich deep crimson. The throat is golden yellow (award of merit).

Cattleya Schröderæ, *Pitts* variety (H. T. Pitt).—A superb variety, with delightfully fragrant flowers. The sepals and petals are soft rose, and the lip is crimson with a rose margin (first-class certificate).

Cypripedium J. Gurney Fowler (J. Veitch & Sons).—This is a cross from *C. barbatum* *Crossi* and *C. Godefroyæ*. The prevailing colour is mauve, paler on the pouch (award of merit).

Epidendrum Clarissa (J. Veitch & Sons).—This is a hybrid from a cross between *E. elegantulum* and *E. Wallisi*. The sepals and petals are purple rose, and the lip purple with a white margin (award of merit).

Jonquil Campernelle (W. Mauger & Son).—A handsome double form of a well known flower (award of merit).

Lælio-Cattleya intermedia Fowler's variety (J. Davis).—This is a supposed natural hybrid. The sepals and petals are soft rose. The front portion of the lip is deep crimson, and the side lobes soft primrose. The throat is blush white (first-class certificate).

Narcissus Alma (Rev. G. H. Engleheart).—A pure yellow variety with a broad spreading perianth (award of merit).

Odontoglossum luteo-purpureum Mossi (de B. Crawshay).—A grand variety. The yellow of the sepals and petals is almost obscured by brown. The front portion of the fimbriated lip is pure white, while the base has brown spots (award of merit).

Phalaenopsis Lady Rothschild (H. Low & Co.).—This is a hybrid from *P. intermedia Brymeriana* and *P. Sanderiana*. The sepals and petals are white tinged with purplish rose; the lip is rose (award of merit).

Polemonium confertum Melittum (J. Jackman & Son).—A dwarf growing plant with pure white tubular flowers (award of merit).

Pyrus Malus angustifolia fl.-pl. (no name).—A strikingly handsome variety with very large, soft rose coloured flowers (award of merit).

Rhododendron H. Elliott (H. & J. Elliott).—A deliciously fragrant pure white variety that should become popular (award of merit).

Rhododendron Shilsoni (D. H. Shilson).—A superb hybrid; see description page 311 (award of merit).

Rose L'Innocence (Paul & Son).—This is a creamy white hybrid Tea of good form (award of merit).

Horticultural Shows.

The Royal Caledonian, April 4th and 5th.

THE extremely unfavourable weather experienced during the whole of the present year found its reflection in the falling off in entries at this, at one time called the Hyacinth show. Fortunately there was no declension in the quality of most of the produce shown. Azaleas and forced plants generally, as well as cut Roses, Apples, and Daffodils, being, perhaps, better than usual. The greatest want of quality was apparent in Hyacinths, in vegetables, and in a less degree in Tulips, all of which were decidedly below the average.

In the plant classes for gardeners, Mr. McIntyre, gardener to Sir Charles Tennant, The Glen, and Mr. Wood, gardener to James Buchanan, Esq., Oswald House, were the only exhibitors of a circular table of plants, the former securing the first prize with a bright arrangement of *Dendrobium nobile* vars., *Hippeastrums*, *Cyclamens*, and forced plants. The latter was second. For a table of Orchids only two again entered, Mr. Mitchell, gardener to J. Wilson, Esq., Bantaskin, Falkirk, being first, and Mr. McIntyre second. Some fine Orchids were shown in the classes devoted to these plants. For four distinct, Mr. Nicoll, gardener to T. Roy, Esq., Craigclowa, was awarded first, a fine example of *Oncidium sarcodes* being noteworthy. Mr. McIntyre was second, a specimen of *Cymbidium eburneum* being well flowered. For one Orchid, with a large specimen of *Cymbidium Lowianum*, Mr. Wood secured first. As already indicated, Indian Azaleas were large and profusely bloomed. Mr. McIntyre secured first prizes for three and one specimen plant. For the former Mr. Bald, Canaan House, was a good second, and Mr. Wood third; Mr. G. Chaplin, gardener to Mrs. Nelson, St. Leonard's, with well bloomed examples, getting first in the class for four in 9-inch pots.

For ten, and also for six forced plants in bloom, Mr. McIntyre was again to the fore with large specimens, and also second for four stove or greenhouse plants in flower, Mr. McCartney, Liberton, securing first for these. Three large and handsome specimen Ferns were shown by Mr. J. H. Pearson, Murrayfield, for first prize in that class. Among other noteworthy exhibits were nine *Cyclamens* from Mr. McIntyre; six *Cinerarias* from Mr. G. Wright, Musselburgh; *Lily of the Valley* from Mr. G. Shearer, Annan; and *Primula obconica* from Mr. Wright, gardener to Lord Breadalbane, Taymouth Castle, a first-class certificate being afterwards voted to this variety; plant dwarf, truss large, colour a shade of pink.

The best twelve, and also the best six pots of Hyacinths were staged by Mr. I. Meiklem, Johnstone; Mr. Brydone, Innerleithen, being second for the first-named, and Mr. Laurie, Crammond, for the second. In a large class Mr. Brydone secured first for six pots Tulips, Mr. A. M'Innes, Musselburgh, a like award for six *Polyanthus Narcissus*, and for an equal number of garden *Narcissus* Mr. Bald was first. These were fine. In the nurserymen's section the Hyacinths were much better than in that of the gardeners. Mr. Campbell, Gourrock, was the only exhibitor for twenty-four, and was worthily awarded first prize. The same exhibitor secured first for six pots Tulips, Mr. Downie, 144, Princes Street, being a good second. Mr. Downie also secured

most of the other prizes for plants in the trade section, including Azaleas, forced shrubs, and decorative plants.

The cut flower section was not extensive. A cup offered by Mr. Barr for a collection of Daffodils brought only one exhibitor, no doubt owing to the late season, and the cup was withheld, a second prize only being awarded. The cut Roses, however, brought out a spirited competition, and were exceptionally excellent. For twenty-four blooms Mr. Manson, gardener to H. Gillon, Esq., Wallhouse, was an easy first. Mr. Armstrong, gardener to Dr. Scott, Musselburgh, second, and in the class for twelve blooms the same exhibitors held a like position, though it was a very close run. The finest blooms were Maréchal Niel, Caroline Testout, Niphetos, Devoniensis, Souvenir de S. A. Prince, La France, and Francisca Kruger. Mr. Pearson, gardener, Beechwood, secured first for twelve Maréchal Niel set up in tubs. Some charming examples of bouquet making and buttonholes were also shown.

In the fruit section Mr. McIntyre was the sole exhibitor of Pine Apples. Two exhibitors showed Grapes—good Lady Downe's—Mr. Smith, Oxenford, being first, and Mr. Kidd, Carberry Tower, second. Mr. McIntyre was first for six pots of Strawberries, and Mr. Galloway, Liberton, second, and again for a dish of Strawberries Mr. McIntyre repeated his success with fine Royal Sovereign. Mr. Smith second with Vicomtesse H. de Thury. The finest culinary Apples were staged by Mr. McKinnon, gardener to Earl Cowper, Wrest, Amptill, Mr. Day, Galloway House, having first for dessert varieties. Apples were fine, well kept, and nicely coloured. Gooseberry, Bismarck, Blenheim Pippin, Blue Pearmain, Hormead Pearmain, Prince Albert, Scarlet Pearmain, and Gloria Mundi being the varieties in the several collections of outstanding merit. An attractive looking variety under the curious appellation of Desse de Buff was shown by Mr. McKinnon, Wrest Park.

Handsome groups of forced plants were arranged by various nurserymen. Mr. Downes having a capital display, mainly composed of forced shrubs, such as *Staphylea colchica*, *Prunus triloba sinensis*, *Cytisus* and *Azalea mollis*. Messrs. R. B. Laird, Pink Hill, had an equally attractive composition, and Messrs. Methven & Sons, Leith Walk, and Messrs. Cunningham, Fraser & Co., Comely Bank, had also attractive arrangements.

Mr. Jones, Lewisham, contributed a table of cut Daffodils in great variety, and also cut Tulips; whilst Messrs. Barr & Son sent from Long Ditton a handsome lot of Daffodils, including some of the newer forms. From Mr. Wright, Taymouth Castle, came a selection of cut trusses of his improved strain of *Primula obconica*, and to these an award of merit was deservedly voted. Mr. McMillan, gardener to Mrs. Carrie, Trinity, arranged a small table with trusses of hybrid Indian *Rhododendron* seedlings, which attracted great attention. As none of them was named the collection as a whole secured an award of merit. Dr. Stewart McDougall had on exhibition a case of insects destructive to vegetation.

Liverpool, April 4th.

St. George's Hall presented a delightful scene to the public on Wednesday last, when the committee of the Liverpool Horticultural Association opened their fourteenth spring show. It was indeed a surpassing ensemble of gorgeous colouring, such as we can only get from the wonderful ranges exhibited in our spring flowers. Ever alive to cater for its subscribers (and after the somewhat poor appreciation of the general public of last Wednesday's show, the subscribers must more than ever be studied), the committee had to give up the popular summer show in favour of the spring show. The show has ever been well regarded by the trade, and this year no less, for many specially interesting exhibits grouped in an admirable manner on square tables occupied the centre of the floor.

Here stood some splendid *Amaryllis* from Messrs. R. P. Ker & Sons, which seemed to take the fancy of the ladies. Also Lilacs, double and single, of many shades; whilst Azaleas of the indica and mollis section showed conspicuous blooms. Messrs. T. Davies & Co. exhibited a charming group of *Acers* in a setting of miscellaneous bulbs, Azaleas, and Genistas handsomely arranged. Especially noteworthy was the exhibit of Messrs. Dicksons, Limited, of Chester, with a most extensive and beautifully arranged stand of *Narcissi*. The trade exhibits ended with the noted Edwardian ware and the clever work in leaf skeletonising from Mrs. Hodgkins, which obtained certificates.

Turning to professional exhibits, many handsome plants were noted, the leading exhibitor being Mr. J. Bracegirdle, gardener to Alderman W. H. Watts, Elm Hall, Wavertree, his group of flowering and foliage plants being characterised by much artistic merit. His miscellaneous bulbous and flowering plants also denoted good culture. Close to him came Mr. T. Gowen, gardener to G. A. Bartlett, Esq., Lynton Lodge, Mossley Hill, who was followed by Mr. E. R. Finch, gardener to Joseph Smith, Esq., Newstead, Wavertree, and Mr. G. Eaton, gardener to W. H. Shirley, Esq., Allerton House, Allerton, with ten hardy and bulbous plants. Hyacinths were extensively staged. The most attractive were those grown three in a pot. Mr. T. Wilson, gardener to O. H. Williams, Esq., gained another most decisive success for arrangements of twelve, six, and three bulbs in a pot, all having fine spikes. Next to these came Messrs. E. R. Finch and G. Leadbeater, gardener to W. J. Davey, Esq., Homeleigh, Grassendale. Tulips

also showed up well, Mr. T. Wilson again taking the lead, with Mr. F. Keightley, gardener to Mrs. Duncan, Grassendale, an excellent second. Mr. J. V. Thompson, gardener to W. P. Sinclair, Esq., Sefton Park, accounted for the prizes for six single, six double, and six *Polyanthus Narcissus*. Mr. E. R. Finch took the first prize in Azaleas, whilst the *Amaryllis* from the same source were very handsome. They were rivalled, however, by those staged by Mr. Keightley, whilst Mr. Bracegirdle took the prize for greenhouse plants. A pretty pale-flowered variety of *Cymbidium Lowianum* gained Mr. G. Eaton the stove plant prize.

The Orchid classes were well represented. Mr. Bracegirdle again led with three plants—one a splendid specimen of *Angraecum sesquipedale* carrying fifteen flowers and buds. Mr. C. Duke, gardener to F. Cross, Esq., Grassendale, showed two fine cool Orchids. Hardy Azaleas and *Rhododendrons* occupied much space, many being shapely and abundantly flowered. Mr. W. Bustard, gardener to T. McLelland, Esq., Aigburth, took honours for Azaleas, *Rhododendrons*, *Azalea mollis*, and one bouquet; Mr. Bracegirdle for six forced hardy plants and four distinct *Azalea mollis*, Ferns, Palms, and some fine Callas. The *Cyclamens* of Mr. J. Heaton, gardener to R. P. Houston, Esq., M.P., looked well; as did table plants from Mr. T. Carling, gardener to Mrs. Cope, Woolton. *Cinerarias*, *Primulas*, and *Freesias* were very moderate. From a show point the exhibition was distinctly good, and the labours involving such were ably carried out by a useful committee, headed by Mr. T. Foster (chairman), Mr. Mercer (vice-chairman), and Mr. Harold Sadler, the genial secretary.

Royal Botanic Society, April 11th.

THE spring show of this society was held in the society's gardens, Regent's Park. The competition was exceedingly poor, but the trade exhibits made a brave display, and were a capital show in themselves.

There was a good competition in the class for twenty-four *Cyclamens*, and Mr. G. Bowles, Church Road Nursery Co., Hanwell, secured first prize with some capital plants. The St. George's Nursery Co., Hanwell, was second. Messrs. A. W. Young & Co., Stevenage, won the first prize for twelve *Cinerarias* with moderate plants, followed by Mr. T. Abbot with still weaker plants. Mr. Geo. Kelf, gardener to Mrs. Abbot, South Villa, Regent's Park, was the only competitor for twenty-four pots of Tulips, which were of medium quality. For twelve pots Mr. G. Kelf was again to the fore with a better display; while Mr. H. Abbot, gardener to C. Newington, Esq., Regent's Park, was a good second.

For twenty-four pots of Hyacinths, Mr. G. Kelf was first with good spikes of King of Blues, Macaulay, gigantea, and La Grandesse. The same exhibitor was also placed first for twelve pots, followed by Mr. T. Abbot. For six table plants Mr. G. Kelf was first with good *Dracaenas* and *Cocos Weddelliana*, and Mr. T. Abbot was second. For six *Azalea mollis* Mr. Kelf was first with six good plants. There were two competitors for the groups of flowering and foliage plants, Mr. Geo. Kelf being again successful. Mr. T. Abbot was second with a more formal arrangement, though the flowering plants employed were good.

Messrs. J. Peed & Sons, Norwood, staged a table of spring flowering plants, such as Lilacs, *Clivias*, *Azalea mollis*, and *Viburnums*, arranged with Ferns. Messrs. R. & G. Cuthbert, Southgate, had a fine display of *Azalea mollis*, arranged with Palms and Ferns. Messrs. W. Cuthbush and Son, Highgate, staged a large collection of *Ericas*, Lilacs, *Magnolia Lenne*, and *Epacris*, with a groundwork of Ferns and Palms. Messrs. Barr & Sons, Covent Garden, arranged a fine collection of Daffodils, *Anemones*, *Scillas*, *Iris*, *Hepaticas*, and *Fritillarias*.

Messrs. W. Paul & Son, Waltham Cross, staged a large collection of *Camellias* in pots, also boxes of cut blooms, with a few other spring flowering plants. A few *Pyruses*, *Cytisuses*, and Lilacs gave delicacy to the group. Messrs. B. S. Williams & Son, Upper Holloway, staged a good bank of spring flowering plants, such as Lilacs in variety, *Azalea mollis*, *Rhododendrons*, and *Crataegus* arranged with variegated Maples, which gave them a good effect. Messrs. J. Laing & Sons, Forest Hill, contributed a display of *Dracaenas*, Palms, *Asparagus Sprengeri*, and Ferns, with *Clivias*, *Ericas*, Azaleas, *Cyclamens*, and *Acacias*, together with many other spring flowering plants.

Messrs. Morle & Co., Finchley Road, arranged a group of excellent *Mignonette* with a few *Genistas*, *Spiraeas*, *Ericas*, and Ferns. Mr. J. Russell, Richmond, staged a table of *Azalea mollis*, chiefly seedlings, also *Viburnums* and *Rhododendrons* in capital condition. A pretty group of alpinas was staged by P. Purnell, Esq., Streatham; the *Primulas*, *Gentianas*, and *Scillas* were attractive and bright. Messrs. F. Cant & Co., Colchester, staged five boxes of cut Roses. The Teas were especially good, The Bride, Cleopatra, Catherine Mermet, Madame Hoste, and Souvenir de Catherine Guillot being most noteworthy; the whole exhibit was fresh and bright.

Mr. W. Rumsey, Joynings Nursery, Waltham Cross, had nine boxes of cut Roses, which were bright and fresh, the blooms of Maréchal Niel and Niphetos, with Mrs. J. Laing, Magna Charta, Margaret Dickson, Mrs. Rumsey, and Général Jacqueminot being most notable. Mr. G. Bowles, Church Road Nursery Company, Hanwell, staged a fine collection of *Cyclamens*, the flowers were stout and fresh. The St. George's Nursery Company, Hanwell, also exhibited a collection of *Cyclamens* grown in their well known style.

The Young Gardeners' Domain.

Bits for the Bothy.

The Foreman. (Continued from page 254.)

THE first taste of power, though it be but a foretaste of full authority yet to come, is exhilarating to those who whilst serving are ambitious to command. The foreman's position, forming, as it does, a connecting link with that of the head gardener, is admirably adapted to the purpose of equipping a young man to rule both wisely and well. In the bothy the foreman, as such, will recognise a wider field of influence; its attendant responsibility he may possibly overlook. It is well for him to see this responsibility, and to accept it, if he will, for it is not compulsory. He may, if he chooses, selfishly take a high seat and look down upon his young comrades of the craft, to the youngest of whom the earlier steps of a good gardener's career are only as yet faltering ones. The question is, Should a foreman accept this responsibility? Is he his brother's keeper? Some may answer, "Oh! there is time enough to show my authority when I am a head gardener." It is an answer which was literally given by one young man, but in reality it is no answer at all. He was one, it may be added, who whilst enforcing obedience during working hours, was unable to command respect at any time by his utterly indifferent attitude and lack of interest in the welfare of others.

Should the foreman unsympathetically deny to his young brother that aid it is his prerogative as an elder to give, he also deprives himself of the exercise of a power which, in its moral force, would eventually be to him a tower of strength. The great lone land of selfishness is an impoverished country, and for those who choose to abide in it, it is able to starve out all that is good and noble in human nature. Oh! That each and every foreman gardener could grasp the spirit of this—these poor words, so feebly expressed; and by his courteous and dignified behaviour, by that innate acknowledgement that he is from hence his brother's keeper, wisely, consistently—aye, even nobly, complete his term of bothy service; and thus armoured, pass on and out into the great battle of life beyond. Never has been, nor ever will be, the force of example so powerful a lever, or so easily applied as it is now, for at this period of life the footsteps of those immediately in front create the deepest impressions, and are the most readily followed by young travellers in the rear.

In some cases the initial stages of the foremanship are beset with little stumbling blocks, trifles truly, but sufficient to cause small side slips it is as well to avoid. These more often occur where the position is filled from the ranks in the same bothy, and familiarity with the journeymen has merged into a little contempt for him as a foreman. In common justice, however, to the bothy, it must be said this feeling is oftener displayed by the outside department than from the inside; this, too, from old hands cynically disposed towards one whom they now regard as being "dressed in a little brief authority." Why men who are, to say the least, old enough to know better should, by presuming on long service, and perhaps a too delicate forbearance on the young man's part, try to make things as unpleasant as possible for him, is not easy to say, but is, unfortunately, a fact not so uncommon as might be supposed. That young men, themselves, are not always blameless in the matter goes without saying, otherwise it would be superfluous to broach the matter here. Some feel too acutely the dignified burden of the foremanship which is placed on their comparatively youthful shoulders, and carry it very ungracefully in their anxiety to display an authority, which may, indeed, be very limited, on every possible occasion. This is a mistake. One can esteem the aspirant who rises to the dignity of his office, but should he take a step beyond and pose for what he is not, then good taste and common sense being conspicuous by their absence, a good deal of unnecessary and unpleasant friction ensues.

As no man is deemed to be a prophet in his own country, so the foreman may, still, never be recognised or obtain his proper status until a change is made to fresh fields and pastures new. However that may be, it is a critical period of a young gardener's life, and there is no reason why he should show undue haste to take up his full commission, the doing of which might be more or less inimical to his prospects. From being a foreman in one situation, and again taking the same post in another, possibly a larger garden, many advantages are obtained. Here, in all probability, his duties will be extended, his knowledge increased, and new social connections formed, as well as an unqualified recognition accorded to his position. He will find here a new, fresh chapter to the closing volume of bothy life, every page of which is of the greatest importance. The advisability of prolonging this stage rather than curtailing it will be obvious to a man of sense, and sooner or later the opportunity will arrive for leaving the bothy for good and all. As a rule the best opportunities seem to come later—when a man has, as far as possible under the circumstances, proved his capability and general worthiness. Most young men cannot at this period regard life other than from its more serious side, nor afford to despise any hints or helps, however small, as aids to an end, hence a little further consideration of matters which are so important may not be deemed irrelevant by them from—THE OLD BRIGADIER.

(To be concluded.)

Hardy Fruit Garden.

Protecting Wall Trees.—From the time the blossoms expand to when the fruit has attained a fair size protection ought to be afforded choice wall fruit. The protection, however, must not be overdone, or the trees will be weakened and the young fruit will fall. Unless the protecting material of a close and heavy character is drawn from the trees during the prevalence of favourable weather, the probability is that more harm than good will result from its use. Stormy wet weather and keen frosts injure the essential organs of the flowers and prevent fruit setting. Apricots, Peaches, and Nectarines require attention first, and if movable material is utilised the arrangements should be carried out in good time. In some cases a double or treble thickness of fish netting is found to be sufficient in warding off frosts. If this is used it may remain as a permanency during the time protection is necessary, because it neither excludes light nor air.

Apples and Pears frequently bloom when the weather is unsettled, but only the blossoms of small restricted trees in the open and wall trees can be dealt with. Protection is most needed when the blooms are fully expanded and the anthers are ripe for distributing their pollen. After that it may be dispensed with, as the young embryo fruit is not so tender as that of stone fruits.

Light poles may be erected over pyramid and espalier trees, tying them together at the top and fixing at such an angle as will keep the material used for protection clear of the trees. It will then be an easy matter to stretch tiffany or scrim canvas over on cold frosty nights, removing it in the daytime. Walls afford some protection as a rule to the blossoms of trees growing against them, but unless situated close to the wall surface they are not absolutely safe, those projecting at a distance being liable to injury. A simple means of protection is that of laying poles against the wall and stretching material over them.

Strawberries.—*Planting.*—There is still time to plant Strawberries if stock is available from nursery beds, or even as small plants brought in without any soil attached to their roots. In the latter case spread out the fibres, covering carefully with fine soil and making firm. Afterwards afford a liberal soaking of water. Both these and stronger plants inserted this spring must have the blooms picked out as they show. Also cut off runners and hoe frequently between the rows.

Treatment of Fruiting Strawberries.—Hoe down weeds between the rows, afterwards laying a mulching of strawy manure which, however, should contain some short material. The latter will furnish nutriment for the roots when washed by rain, while the long, strawy, undecomposed parts will provide a clean bed for the ripe fruit. Soot scattered round the crowns, but not among them, proves highly beneficial in banishing slugs and other insects. Before applying the mulching fork in 3 ozs. of superphosphate to the square yard. This is admirable for inciting root action. To have an immediate effect upon growth apply nitrate of soda 1 oz. to the square yard. Also give liquid manure occasionally, and more freely after fruit has set.

Young Strawberry Plantations.—The removal of the flower trusses from all but early autumn inserted plants should be practised. A heavy mulching of rich manure ought not to be applied to young and vigorous Strawberries growing in good soil the first year, as it will be likely to cause superabundant leafage. For the present frequently hoeing the surface soil between the plants will induce a steady growth. When the hot weather arrives a light mulching of flaky manure may be given, which will tend to keep the soil moist.

Planting Outdoor Figs.—Well drained soil of a calcareous character must be provided for Figs, and the position for planting ought to be a warm and sheltered wall. The border need not be more than 6 feet in width for a high wall. Make the soil very firm before planting, which may be carried out now.

Pruning and Training.—Maiden trees, which are the best to plant, should be shortened to 15 inches. When growths push select two of the best and encourage them to grow strongly, and as far as possible equal in vigour. The following season shorten each shoot back half its length, and allow two strong breaks from each to form main branches. From these the fruiting shoots may extend, chiefly from the upper sides of the branches, and must be left at full length for fruiting. Each year, however, some may be shortened closely back, while others are left at full length to be in their turn pruned back. By this method shoots are produced one year to be fruited the next.

Disbudding.—Young fruit trees which start vigorously into growth usually push more growths than it is desirable should extend. Disbudding or rubbing off young shoots when quite small offers a ready means of regulating the position of shoots for forming a shapely tree. The operation may be commenced as soon as the buds burst, first

removing all those in inconvenient positions, such as on the under side of branches, and on those parts nearest the wall in wall trained trees. Disbudding should be a gradual operation, never removing too many growths at once. Of those growths which are well placed a reduction in number ought to be gradually effected, so that the branches subsequently will not be crowded.

Fruit Forcing.

Cucumbers.—The bright weather recently prevailing has resulted in grand fruit, though the nights have been unusually frosty, and the temperature has fallen to a correspondingly low degree. Attend to tying out the growths, stopping one or two joints beyond the fruit, removing bad leaves and exhausted growths, so as to maintain a succession of healthy, fruitful shoots. Water will be needed copiously by plants in houses, and liquid manure once or twice a week may be given with advantage. Syringe the foliage and walls daily at closing time or about 3.30 P.M., and damp the house well in the morning and evening. Shade only to prevent flagging. The floor of the house may be sprinkled in the evening occasionally with liquid manure, or sweetened horse droppings sprinkled on the bed will answer the two-fold purpose of evolving ammonia to the benefit of the foliage and supplying nutriment to the soil.

Plants in pits and frames will hardly need shading as yet, but they must not be allowed to flag. Use tepid water through a fine-rose watering can at about 3 P.M., closing the lights at the same time; but as the nights are as yet cold, be careful that the foliage becomes dry before dark. Close early, employ a thick covering, as a double thickness of mats. Maintain a good bottom heat by linings, renewing them as necessary. Preserve a night temperature of 70°, 70° to 75° by day, 80° to 85° or 90° from sun heat, ventilating from 75°, being careful to avoid cold and drying currents of air, and close sufficiently early to run up to 90° or more. Sow seeds of ridge varieties, and keep young plants of these near the glass.

Melons.—The fruits of the earliest plants are growing large, and must have the supports lowered, while those commencing to swell should be provided with them. Stop the laterals frequently, and thin them where they are crowded. Afford water or liquid manure copiously to plants on which the fruits are swelling, but avoid excesses of liquid manure or top-dressings likely to injure the roots, or the fruit in consequence of loss of feeders may not finish satisfactorily. Plants coming into flower should only have water to prevent flagging, and a drier atmosphere is essential to a good set, especially in the case of vigorous plants.

Attend regularly to setting the blossoms. Stop the shoots one joint beyond the flowers when impregnated, and after the fruits are set pinch the sub-laterals to one leaf, and remove superfluous growths. Avoid giving stimulants to plants until the fruit is swelling, when liquid manure may be afforded liberally, especially to plants carrying heavy crops, until they are well advanced towards ripening. Maintain a night temperature of 70°, 70° to 75° by day, and 85° to 90° from sun heat, and close early so as to run up to 90° or 100°. Ventilate freely in favourable weather, closing early with plenty of sun heat, when the plants may be syringed lightly, except such as are in flower. If canker appear at the collar rub it out with quicklime, repeating if necessary.

Peaches and Nectarines.—*Earliest Forced House.*—Discontinue syringing when the fruit commences to ripen, or it will cause the skin to crack and impart an unpleasant musty flavour. It is very important to have the trees quite free from insects by the time the syringing ceases. If there be the least trace of red spider apply an insecticide, and follow shortly afterwards with a forcible syringing, repeating the process if necessary, so as to thoroughly free the trees from the pest. It is only the very early varieties that will be ripening; the others must be well syringed, and have abundant supplies of water and surface mulchings of short manure or rich material.

Second Early Forced House.—Trees started at the new year have the fruit stoning, and will need care in preventing checks from sudden fluctuations or depressions, the night temperature being kept steadily at 60°, with 5° more on mild nights, whilst on cold nights it may fall to 55°, 65° by day in dull weather, 70° to 75° on cloudy days but with clear intervals, ventilating from 70°, and freely above 75°. Attend to tying-in the shoots as they advance, and encourage no more growths than will be required for future bearing, the extension of the trees, and the swelling of the current crop. The trees must not lack water at the roots, affording liquid manure if they are heavily cropped and not making satisfactory growth, but avoid undue excitement to trees in full vigour, as any impulse given to growth during the stoning is apt to affect the process disastrously. Syringe twice a day in bright weather, and if necessary apply an insecticide, it being imperative that the foliage be kept clean.

Trees Started in February.—Thinning should commence when the fruits are the size of horse beans, removing the smallest and those on the under side or at back of the shoots. Retain sufficient to admit a further thinning when they are the size of marbles, and then only a few more need be left than are required for the crop, leaving those that are best situated for receiving air and light. Disbudding must not

be neglected, and laying in the growths required for next year's bearing wood will need careful and timely attention. Syringe the trees twice a day when the weather is bright, occasionally only when dull, and let the second syringing be at closing time or early in the afternoon, so as to have the foliage fairly dry before night. Increase the temperature to 55° or 60° at night, 60° to 65° by day, ventilating from the latter, and increasing with sun heat to 70° or 75°.

THE BEE-KEEPER.

Foreign Bees.

ARE foreign bees an advantage to bee-keepers in this country whose chief aim is to obtain as large a surplus of honey as possible? We are induced to ask this question after having had a wide experience of the different varieties. We do not favour them, for reasons which will be given. We recently visited an industrious bee-keeper who had numerous stocks of bees, which were in good condition and managed on the modern system; he had never kept any other but natives, which had always done well. Last autumn he was advised to try a change, so ordered a Cyprian queen from a well known dealer; but the queen arrived dead. He was disappointed at his first attempt in introducing a foreign queen into his apiary, and intended trying again. We advised him to keep natives only, as they had done so well for him in the past.

The only reason given by the majority of bee-keepers for trying one or other of the varieties of foreign bees is simply for a change. After going to the expense of procuring them they find they do not obtain more honey than they did previously with the common blacks. It is impossible to keep them pure in this country, and they become a nuisance when crossed owing to their propensity for stinging.

It is now upwards of forty years since the late Mr. A. Neighbour introduced the Ligurian or Italian bee. These came with a great reputation as honey gatherers and were supposed to have a longer proboscis, by means of which they could extract the nectar from the red Clover. It is a well-known fact that the tubes being longer in this variety than is found in the white Clover, the bees are unable to work on it. This fallacy was believed in for many years, but it is now practically exploded. This variety, as well as the Cyprian, is easily distinguished by the bright yellow bands round the body, which cause them to be much admired. They are easy to handle when pure bred, and are good tempered. They are, however, such inveterate swarmers, that they soon become crossed with our native bee; they are then known as hybrids, which are invariably good workers, but often very vindictive.

The Carniolan is another foreign bee that is not so attractive in appearance as the above; they are persistent swarmers which it is almost impossible to stop. We have seen upwards of thirty queen cells in an ordinary hive at one time. If the queen cells are removed they are soon replaced by others, and on the first bright day the swarm comes off, and by the time the swarming mania is over the honey harvest is past. It is therefore not advisable to import foreign queens even for a change.

Our Native Bee.

Our native black or brown bees are known throughout the country. As a rule they are quiet and easy to handle; of course they will protect their stores if molested. Every bee-keeper knows there is a right time and a wrong time for handling bees. If, for instance, it is a windy day, and the bees are unable to venture far from their hive, they are bad tempered, and should not be interfered with. If, on the contrary, the day is bright and warm, and stores are coming in freely, they may be handled with impunity without any danger of being stung. They are hardy, and if well supplied with stores, invariably winter well. They are also good workers, and if the weather is favourable, will store a surplus if it is possible to obtain it in the district. They are equally good for either comb or extracted honey, and what more can be wished for in any variety of bee?

Another important feature we have found since we have kept the native bee as true as it is possible to keep them, is their freedom from swarming. We now find it possible to keep numerous colonies of bees without the swarming mania spreading throughout the hives. Management may have something to do with this satisfactory state of affairs. We, however, do not think it possible to have this freedom from swarming with any other variety of bee.

It will thus be seen that we give a preference to our native bee when honey production is the bee-keepers' chief aim. But as shown, some of the foreign varieties are handsome in appearance, and may be kept for that reason alone.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Mixing Paris Green with Liver of Sulphur (W. H. Y.).—Paris green will not mix with liver of sulphur, soap, or paraffin washes, so that you will need to apply the liver of sulphur solution separately, and also that of the Paris green mixture. This will occasion separate sprayings, but Paris green can be mixed with Bordeaux mixture; thus one spraying answers for both fungous diseases and biting insects, or caterpillars.

The Gooseberry Apple (J. W.).—Your specimens are fine examples of this old variety, which is described by Dr. Hogg in the "Fruit Manual" as follows:—Fruit, above medium size; roundish, with obtuse ribs on the sides, which extend to the crown, where they form ridges. Skin, deep lively green, with a tinge of brownish red next the sun. Eye, open, not deeply sunk. Stamens, median; tube funnel-shaped. Stalk, short. Flesh, greenish white, very tender, juicy, and with a fine agreeable and subdued acidity. Cells, obovate; axile, slit. A very valuable late-keeping culinary Apple, which comes into use in November and continues "till Apples come again." It is said that because the fruit remained firm till Gooseberries were large enough for tarts that the Apple received its name.

Cannas from Seeds (R. M. D.).—Though we have had fair success by soaking the seed for twenty-four hours in water at a temperature of 130° to 140°, we find it absolutely necessary to insure germination of every sound seed to chip or file the outer skin of Canna seed before sowing. This is of the utmost value, as the moisture from the soil reaches the embryo or young plant, and it must either grow or rot. A Cucumber or other warm house is the best place for sowing the seeds, a mixture of sand and leaf mould being suitable for them. It is a good plan to sow the seeds singly in small pots, covering 1½ or 2 inches deep, as this prevents any damage to the roots, which are somewhat brittle and liable to injury or check in potting or dividing the plants out of seed pans or boxes.

Definition of Chrysanthemum Buds (Idem).—The buds are:—1, First break. This means the formation of a flower bud in the point of the young growing stem, which causes other branches to start from the axils of the leaves below the point where the flower bud formed. This may answer to what you term the "first crown bud," and forms during the early part of May in some varieties and others early in June. Such of the shoots as are allowed to advance in growth in time produce similar buds, known as "second crowns." At whatever time a bud forms in the point of a shoot, and other growths start from immediately below it, that bud is a crown bud, and perishes if the growths below are not promptly removed. 3, The name terminal bud implies a bud formed at the apex of growth, and no other growths start below it, but a cluster of flower buds instead. These are not appreciated by growers of plants for large blooms because the flowers are too small, as a rule, for exhibition stands, even if only the central bud is allowed to remain. The subject is clearly illustrated in Mr. Molyneux's book on Chrysanthemums. Securing and setting or "taking" crown buds at the proper time is an important point with exhibitors.

Potentilla fruticosa (F. J. B.).—On page 313 you will find a description of this perennial, together with an excellent illustration, which will, we hope, convey all the information you require. Do not hesitate to write if you want assistance on this or any other horticultural matter.

Cotoneaster microphylla Twigs Infested with Scale (Cymro).—The twigs are badly attacked by the Apple mussel scale or oystershell bark

louse, *Aspidiotus conchiformis* or *Mytilaspis pomorum*, one of the twigs being quite killed by the pest. The insects are now hibernating in the egg state beneath the parental coverings, which, like single valves of small mussel shells, adhere to the twigs. From these eggs the larvæ hatch out about the middle of May, and appear as mere specks to the naked eye. The eggs are magnified twenty times in the accompanying illustration, fig. 87, E at g; and the larva is shown magnified with natural size on side at H. The young lice move about over the bark for a few days, when they fix themselves upon it, inserting their tiny beaks far enough to reach the sap. Here they continue to increase in size, and by the end of the season have secreted scaly coverings similar to those shown in the illustration at K. The most effective treatment is spraying with a solution of caustic soda and pearlash, when, as in the case of Apple and Pear trees, the plants are quite dormant; but *Cotoneaster microphylla* being an evergreen, your best plan will be to assail the larvæ as they hatch out in May and June with paraffin emulsion, at the rate of a gill of paraffin (quarter of a pint) to 5 gallons of

to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. The practice of pinning numbers to the eyes of the fruits tends to destroy one of the most characteristic features and increases the difficulty of identification. When Plums are sent to be named young wood of the trees should accompany them. Leaves of the trees are necessary with Peaches and Nectarines, with information as to whether the flowers are large or small. (J. W.).—Your specimens most closely resemble the Gooseberry Apple; see description on preceding page. (H. L.).—1, Hoary Morning; 2, Wellington; 3, Dutch Mignonne; 4, Newton Wonder, in excellent condition; 5 and 6, not recognised, probably local seedlings. (W. J. E.).—1, New Northern Greening; 2, Wellington; 3, Cockle's Pippin; 4, Bess Pool; 5, Bramley's Seedling.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. J. R.).—1, *Acacia Drummondii*; 2, *Rhododendron fragrantissimum*; 3, *Daphne Mezereum*; 4, *Polypodium pedatum*; 5, *Doodia caudata*. (L. T.).—1, *Dendrobium nobile nobiliss*; 2, *Epidendrum vitellinum*; 3, *Odontoglossum luteo-purpureum*; 4, *O. triumphans*, see excellent varieties illustrated on page 301; 5, *Dendrobium primulinum*; 6, *D. fimbriatum oculatum*. (M. H.).—1, a good variety of *Clivia miniata*; 2, an *Amaryllis* or *Hippeastrum*, which probably never had a distinctive name; 3, *Streptosolon Jamesoni*. (R. C. J.).—1, *Phaius grandifolius*; 2, *Lycaste Skinneri*; 3, *Dendrobium Wardianum*; 4, *Angraecum sesquipedale*. (J. W.).—*Odontoglossum Rossi majus*; 2, *Blechnum occidentale*; *Selaginella canaliculata*.

Plants, Injurious and Otherwise.

RIGHTLY or wrongly, there is a great deal of ignorance shown respecting the properties of many weeds and plants that are found on almost all farms. Of course a weed is always out of place, but as weeds form part of the primeval curse, we shall not be rid of them yet awhile. Some may possess good properties; others, alas! are undesirable, if not even actually dangerous, and some again are actively dangerous.

In the Journal of the Royal Agricultural Society for last year is a most interesting paper by the consulting botanist, W. Carruthers, Esq., on his work during the year. It is full of useful information, and well worth a close reading; but as perhaps few of our readers will have a chance of coming at the article in question, we propose to mention some of its salient points. Part of this gentleman's work is the examination of seeds and their testing as regards the germinating powers; this is a most useful work, as farmers should have full value for their money. The seed bill is always a heavy one, and a season missed is missed for ever. That field shows signs for years to come where the growth of seed has been irregular and "chancy." Mr. Carruthers is consulted by many members of the Royal as to the injurious properties of many plants. So often mysterious ailments arise among stock, and owner and vet. are both sadly puzzled to see what the real mischief springs from. Some stock appear to possess curiously morbid or depraved appetites, and notwithstanding good pasture, will leave it to eat all manner of rubbish. (By the way, we once knew of some incalvers who feasted royally on nitrate bags that had been washed and hung out to dry. The bags disappeared, and the cows followed quickly, or at least the greater part of them.)

We are all ready to admire the beauty of a grass field rendered "golden" by Buttercups; nothing can be gayer or brighter, and yet every species contains an acrid and irritating juice. Generally it will be found that stock will leave Buttercups severely alone, but a case occurred last year where it might be inferred that, for some reason or

other, both ewes and lambs and young horses ate of the Buttercup in a field of Clover. This was the Upright Buttercup (*Ranunculus acris*), and the effect on the young animals was excessive scour. The juice of this plant is extremely acrid, and would produce the mischief laid to its charge. The Small-flowered Buttercup (*R. parviflorus*) also possesses in a green state a very acrid juice, but when the plant is dried into hay this property disappears. The Pilewort (*R. ficaria*), which is also much found in damp meadows early in the season, is also acrid, but in a less degree than the others; it occupies the place of better feeding grasses or herbs.

There is another plant very common in some neighbourhoods, and known by the names of "Lords and Ladies" or Cuckoo Pint (*Arum maculatum*); it has been known to act fatally on children, and would be most harmful to stock should they get any of it, as it has an acrid and pungent juice. We should hardly imagine that stock would eat it except in cases where pastures were very bare, or the appetite very depraved.

There were cases reported of the death of calves, which said calves had had access to both Laurel and Rhododendron trees. How this came about we are not told. It is a warning to be most careful to keep stock from ornamental shrubs of this nature, for they abound in that most poisonous of essences—viz., prussic acid. The form this poison takes is narcotic, and the symptoms are drowsiness and stupor. We remember a case where a tribe of most valuable Shorthorns got at shrubs of this sort across a frozen lake; that danger had not been foreseen or guarded against. In another case the natural fence was a stream of some depth which, owing to continued drought, became passable—and stock always like to forage about. We have known cases where gross carelessness has been shown in the disposal of clippings and cuttings of shrubs. The only safe method is to make a good bonfire. (Discarded Christmas decorations are often left lying about in a most haphazard manner, and neither decayed evergreens nor fine wire are desirable feed.) We remember a case where a careless boy mowed grass under a Laburnum tree just as the seeds were shed, and carefully conveyed it to a yardful of pigs—result, several funerals. Mr. Carruthers also finds death was caused to young cattle by the eating of *Nicotiana affinis*. It seems strange to us how they got a chance of tasting this particular growth; it is generally only found in gardens.

Need we speak of the poisonous nature of Yew? The action is so quick that there is time for no remedy; indeed the first intimation that anything is wrong is the dead body of the victim. It has been supposed that only half-withered bits of Yew were injurious; of that the authorities seem uncertain; but there is a concurrence of opinion that the fresh young shoots are fairly safe, though not a desirable feed.

There are two other plants that have been found to be fatal to stock not quite so well known as some of the aforementioned. The first which was fatal to sheep and cattle is a habitant of ditches and watercourses, the English name being Waterdrop Wort or Water Hemlock. It is supposed that stock accustomed to grazing in meadows where this plant is found learn by instinct to avoid it; and it would be only stock from upland pastures bent on trying all herbage in their new quarters would make a meal of Water Hemlock. Another plant to be carefully avoided is Dogs' Mercury (*Mercurialis perennis*). Left to themselves stock will not touch it, and in cases where it has proved fatal it has been found that the plant has been introduced to the stable among cut fodder. As it grows in woody or shady places there can be little or no excuse for the carelessness of the grass cutter. Fodder from such situations is neither good nor desirable.

After two years where acorns have been most plentiful, we are hardly likely to have another prolific season; still it is as well to be on the look out. There have been so many cases of illness and death from over-indulgence in this particular, shall we say fruit or nut. Like the schoolboy's rich cake, divided it would do no harm, but gobbled up by one the results would not be pleasant. Unfortunately, animals as well as boys do not always know when to stop.

Mr. Carruthers has been able to prove a "not guilty" in the case

of several suspected plants, such as Hogweed or Cowkeep, which stock will partake of freely; and Self-heal, which is simply a weed instead of a fodder plant. There has been an idea prevalent in some districts that Ground Ivy (*Nepeta Glechoma*) will cause abortion in foaling mares. This is quite an aspersion, as the plant is quite harmless. The seed of the Corn Cockle plant, which will usually be found in the small offals of corn reserved for poultry, are of a distinctly poisonous nature, and care should be taken to sow no sample of corn in which these seeds are found. There is a species of Bitter Vetch (*Lathyrus*), the seeds of which contain narcotic poison, and therefore were very much out of place in a sample of horse corn.

Year by year the work of the consulting botanist grows and increases—people are more alive to the value of assured knowledge on uncertain questions, and having regard to the national importance of such researches, and the fact that Continental nations pay for and organise similar ones out of national funds, it would not be unreasonable to ask the British Government to do the same. Now that the Royal Agricultural Society finds it to be necessary to suspend the touring nature of its annual show, and to make the show a fixture, in order to make ends meet, it might surely be relieved of the burden of carrying on public experiments and researches.

Work on the Home Farm.

We are having finer weather, as there has been only a wet night to break a fine week, so drilling proceeds merrily. We have met one farmer who had all sown by April 1st, but we must imagine that he is a *rara avis*.

We have much more satisfaction in drilling Barley now, as there is a better mould, and with a cloud of dust behind the drill there is a good prospect for a crop. We see many farmers sowing or drilling small seeds immediately after the Barley, and harrowing all in together. This is a good plan for the grasses, but Clovers may be buried too deeply, therefore we prefer to Cambridge roll the land after the Barley has been harrowed in, then sow the seeds on the roller seams. One more harrowing will well cover the seeds, whilst leaving them near enough to the surface. Some land is so given to weeds that it is absolutely necessary to postpone the sowing of Clover until after the Barley is up, but we do not like the system, and would not practise it unless absolutely compelled, as our own experience has quite convinced us that the harrowing of growing Barley is responsible for unevenness in many otherwise good samples.

Harrowing Wheat is quite another matter, and, as the weather is now favourable, it should be rolled, if that has not already been done, and well harrowed. We have never yet seen anything but good come from harrowing Wheat, if it be done before May. This is the time to put salt on, if it be thought desirable. Four cwt. per acre, costing 3s. 6d., will pay to apply on light land, especially if nitrate of soda be used as well, for the salt has a good effect on the healthiness of the straw. Nitrate should be applied this month if at all, 1 cwt. per acre is enough for any Wheat crop, and we have more often used about 80 lbs. per acre.

Spring Tares for use in harvest must soon be sown. We have generally sown autumn Tares in April to come in after the autumn sown ones, as we think this variety produces better green fodder than the spring sort, as it is not so frothy and watery. Autumn planted Cabbage are now beginning to grow nicely, and they must be kept clean by the use of the hose and hand hoe. 1 cwt. of sulphate of ammonia per acre will do this crop good. It should be sprinkled between the rows and skerried in. It may not be near the plants, but the roots will find it as it gets washed down, and nitrification takes place.

DAINTINESS OF SHEEP.—Sheep deserve the name of "neat cattle" much more than do the bovine race. They are more dainty about their food and water than any other animal we know, unless it be a thoroughbred horse. The food that other animals have left and have breathed upon they reject at once. They will not pick fodder or grain from the mud. They will not drink from a dirty puddle, and they would jump a rod or go a mile round sooner than to wade through one, or through a muddy place in the road. In all this they must be humoured, and if the hens roost on the sheep racks, and the floor of the sheep shed is not kept dry and clean, we cannot expect thrifty sheep or strong healthy lambs. They also object to the grain if it is mouldy, or if rats have frequented the bin, and will go hungry with grain or rotten roots before them if the smell is not such as they approve. The careful shepherd, says a contemporary, should keep all this in mind.

BARR'S GOLD MEDAL DAFFODILS

The Most Lovely
of all Spring Flowers.

The Finest Collection of

DAFFODILS

IN THE WORLD,

NOW IN BLOOM

AT

BARR'S NURSERIES,

A FEW MINUTES FROM SURBITON STATION (S.W.RLY.)

VISITORS INVITED.

Now is the time to select varieties while in bloom for delivery in autumn.

Climbing Plants! Climbing Plants!

FOR COVERING WALLS, TRELLISES, ARBOURS,
SCREENS, PILLARS, &c.

Well established in pots in various sizes and prices, suitable for any situation.

IVIES.—Grand plants, variegated and green, quick growing varieties, 1/- to 1/6 each; 9/-, 12/-, and 15/- doz.; extra large, 2/6 and 3/6 each.

CLEMATIS.—All the best known varieties, in lovely colours, stoutly grown, from 1/- to 2/6 each; extra large, 5/- each, suitable for forcing.

ROSES.—One of our leading lines, always kept up to date by the latest novelties; grand plants, ready for immediate use, 2/6 to 5/- each.

HONEYSUCKLES.—Quick growing kinds, all the best sorts, sweetly scented, yellow, white, cream, rose, scarlet, &c., 1/- to 2/6 each, according to variety.

PASSIFLORAS.—Passion-flowers, fine plants, well established, grows quickly, 1/- to 5/- each.

JASMINUM.—Rapid growing climber, great favourite, grand for verandah, lovely perfume, 1/-, 1/6, and 2/6.

VITIS.—Foliaged Vines, very ornamental and beautiful, charming for festooning, fruit exceedingly pretty, 2/6 to 3/6.

AMPELOPSIS.—Fine plants, in several varieties, from 1/- to 2/6 each.

WISTARIAS.—Splendid twiner, single and double sorts, 2/6 and 3/6 each. &c., &c., &c.

Stove and Greenhouse Sorts in all the known kinds. See Catalogue. PRESENTED—Manual and Reference Guide for 1900, giving detailed descriptions, just issued, the most complete list published, post free.

CLIBRANS' ALTRINCHAM.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM

AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is ECKFORD'S GIANT SWEET PEAS. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40! Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that ECKFORD'S SEED, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties
PANSY. World-famed strain of FANCY SHOW PEACOCK, and FLAKED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! **ILLUSTRATED** Catalogue & Cultural Notes POST FREE! If you love Gardening send for one!

Journal of Horticulture.

THURSDAY, APRIL 19, 1900.

The Journal of Horticulture can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

Pre-Victorian Days.

THIS is my Golden Wedding year of authorship, for I may now in my eighties fairly boast of the feat of having bent the printers' backs off and on for fifty years through this Journal. My baptism of flower-show took place in 1835, or perhaps a year later. This uncertainty makes me think I am growing old, as I do not always retain the power to remember names and dates. However, I must not complain. Suffice it to say I happened to be in London in those days of William IV., with the Rev. G. W. St. John, a near neighbour of T. A. Knight, the noted president of the R.H.S. Mr. Walpole, then of the Treasury, married a daughter of Mr. Knight—they were great friends of Mr. St. John's, their town house being in Upper Wimpole Street, Portman Square, and thither Mr. Knight annually resorted to be near Chiswick for the chief show. A peculiarity of Mr. Knight's was never to sleep upstairs in London, so the back dining-room had to be fitted up as a dormitory on those occasions. The footman having sprained his ankle, it prevented him taking his place on the carriage to Chiswick, so application was made for me to officiate, which I gladly accepted. I can see it all in my mind's eye now—a vast gathering of the élite from the West End and elsewhere. The pavilion and tents filled with horticultural productions of all kinds—flowers, fruits, and vegetables; also half-hardy and hothouse plants in huge pots and tubs, large and densely bloomed and trained in pyramidal and globe shapes. The gardens and lawns were then in all their integrity, furnished with rare and beautiful trees, which, alas! have nearly all long since had to give way to bricks and mortar.

It was a gay sight. Moving among the crowd of fashionables were members of the committee, judges, editors of the then sparse gardening periodicals, the nurserymen and gardeners exhibiting, young and active, among whom was Donald Beaton in all his glory. Little, however, did this young man then dream that he would in

No. 2690.—VOL. CII., OLD SERIES.

after years sit as a member of the fruit committee in the room of the pavilion devoted solely to that purpose—a position gained after years of self-searching toil, and a portfolio of first-class certificates and other awards. “Passing rich on fifty pounds a year,” I managed to keep myself in evidence with the R.H.S., not excepting the anxious troublous times at South Kensington with the Commissioners of the 1851 Exhibition, and the “inevitable Dilke.” I exhibited, too, a great deal in those years, though I seldom did so for competition prizes.

After the aforesaid fête in the Chiswick Gardens, in 1835, I believe the next day, we left. The old stage coach started in the morning from the Green-Man-and-Still, Oxford Street, for Reading, where it arrived in the afternoon, allowing me plenty of time to look about and to procure seeds at the Brothers Sutton. I have dealt with them ever since, and for the last three decades done business with the firm, but *O tempora! O mores!* How many wonderful changes have happened in Reading since those days! Leaving by coach early next morning, we wended our way to Oxford, and after looking over the Botanic Gardens, stayed to sleep at the Mitre. Starting again at an unrighteous hour on the following day for Worcester, we passed through Woodstock, over those Chipping Norton Hills when it snowed. After that the early breakfast at the Moreton-in-the-Marsh Inn afterwards was something to be remembered. Thence we made for Worcester, where the cathedral served to rivet one’s attention for the rest of the day, and rising with the lark, were off again next morning, through a lovely country to Ludlow, where we arrived about midday, posting by chaise from the Crown to our destination at Stanton Lacey.

To all my gardening friends at Ludlow and around I meted out my impressions obtained at Chiswick. Having become tinctured with flower-show I began to preach flower-show, but I soon found out that agitating for a local show was to be a long task. The majority of the gentry did not then favour shows, being under the impression that their best products would disappear for the advantage and glorification of the gardeners. However, I did not despair, but waited for a friend at court. After long waiting it came to pass in this way. My flirtations with the Cinderella of Nature, the Potato, began to be “talked about,” and reached the ears of Mr. Knight, who was himself inclined that way. Through him I procured the attention of the Hon. Robt. Clive, M.P., of Oakley Park, Bromfield, who took a great interest in the culture of that esculent.

I often walked over to Downton Castle, and in course of time became on speaking terms with Mr. Knight anent many things, the Cinderellas in particular. He was a tall, kind, sociable gentleman, and would converse with both young and old. I have descendants of his Elton Pine Strawberry, which he gave me about this time of year sixty years ago, and there are very few late sorts that can equal it. Mr. Knight was his own head gardener, the foremen being old retainers about him who carried out his multifarious instructions. His visitors sometimes had to look out in order to dodge the rotten Apples and Pears which would come flying out of his fruit room window upon the lawn. Well, for a long time, as I mentioned above, I had been waiting for an opportunity to speak with Mr. Knight on my pent-up subject. One day Mr. Knight happened to be in one of his glass houses when I was passing; I paused, he invited me to enter, and pointed out what I thought to be some extraordinary experiments he had proceeding there. They related to the growth of certain plants which were fixed upon the tires of small wheels kept perpendicularly slowly whirling round upon their axles by clockwork movements, in some way like a roasting-jack, against the sun, the roots growing in pots being now up, and then the foliage and branches. It was altogether very funny, and past my understanding. I know I found it difficult to start unfolding what I had on my mind, but then was the time. Chiswick, however, came to the rescue. A chat about the shows there gave me an opening to hint what a capital place the greensward within the walls of Ludlow Castle would make for a local flower and fruit show. Mr. Knight said my propositions were right, but the difficulties to arise were too great, unless I had sufficient power and guarantee at

my elbow to assist to carry them out, which of course in my position I had not. Hence my enterprise lapsed.

I then determined to rest upon my oars, as I felt I was twenty years before my time. Do you remember the meeting of the Royal Agricultural Society of England at Shrewsbury in 1845? I was staging at that fine old mansion, Condover Hall (Mr. Smith Owen’s), for that occasion. The gardens at “Condor” were noted and beautiful, and as a matter of course I foregathered with the gardener and made acquaintance with other local sons of the spade, with whom I never lost an opportunity of pressing my favourite topic. I suggested, as there was not then a horticultural show in the county, that Shrewsbury being the county town would do well to take a lead in that way. The subject became talked about, but though that was in some sense the sowing of the seed, years had to pass before I saw my dreams become a reality. My views had to await the growth of the railways, and with them the spread of broader notions of business and gardening. But I have been luckier than many reformers. I have survived the day of struggle, and now, in the eventide of a long life, I see every village celebrating its annual flower-show, and the horticultural festival of the West of England the event of the year.—ROBERT FENN.

The Value of Tree Shelter.

THE value of trees planted near gardens as wind-breaks from the north, west, and east has frequently been remarked upon. It is a matter, however, that has not always been sufficiently considered when the sites have been chosen. Garden walls, even when lofty, or say 14 feet in height, do not give anything like a proportionate shelter, in winter and spring, to the garden that trees do in suitable proximity. In a large garden cold east or north winds will pass over a garden wall, and at some yards distance from it the sheltering influence is scarcely felt, when there is open country outside it, and few deciduous or evergreen trees to filter it. Such gardens afford object lessons at the present time in the dearth of outdoor green vegetables, especially when compared with others suitably protected.

I had an instance quite recently clearly exemplifying the value of tree shelter in a good sized kitchen garden, this being bounded at a short distance away with evergreen trees. Here was much the best plantation of Broccoli I have seen anywhere, mostly of Late Queen, Model, and Veitch’s Maincrop. Winter greens, too, were abundant, and had been all the winter. It is needless to say that such a satisfactory vegetable supply has been most enviously viewed by gardeners less fortunately situated. This garden had no walls, but instead, hedges and tree belts, which in severe winters are most effective.

Walls are a necessity for the growth and protection of choice and tender fruits, and also for security against the raids of persons mischievously inclined, but their presence, apart from outside aid, does not afford so much shelter as is commonly supposed. They would be more effective if the enclosed space were intersected by dividing walls—that is, in the case of a large garden. It is curious how the force of westerly gales creeps into enclosures even when ample provision has been made to keep it out; tall plants and pit lights, for instance, can in few cases be left without concern during the autumn.

The nature of the soil has much to do with the condition of spring crops, apart from shelter, as also does the aspect. Soil overlying gravel or sand is much warmer than that of an opposite character—clay; and a garden having a southern slope possesses advantages over another which faces east or north, or, indeed, a perfectly level one; while in other respects the latter claim some particular advantages from a labour point of view over gradients more or less pronounced. It, however, matters not what the aspect or soil may be, there is the same value in tree shelter both for the growth of fruits and vegetables.—W. S.

**Cattleya intermedia Fowler's Variety.**

At the meeting of the Royal Horticultural Society held in the Drill Hall on Tuesday, April 10th, an Orchid exhibited by Mr. J. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford, was recommended a first-class certificate under the name of *Lælio-Cattleya intermedia* Fowler's variety. This is favouring the assumption that the plant is a natural bigeneric hybrid, though it has hitherto been regarded as a Brazilian species. Whatever it may be, the flower shown (fig. 88) was exceptionally beautiful, and received warm expressions of admiration from everyone. The shape of the flower is well depicted in the illustration. The sepals and petals are very delicate rose. The front portion of the splendid lip is deep crimson, while the side lobes are soft primrose and the throat bluish. It was well deserving of the honour accorded to it by the Orchid Committee.

Dendrobium**Leechianum.**

As showing the variation in hybrid Orchids this very fine plant is worthy of note. It is of course from the same parents as *D. Ainsworthi*, but it is very distinct, and I always consider a far better grower. In a short time healthy little bits make fine plants if well treated. They are best raised from flowering stems, and if these are taken off directly the blossoms are past and laid in pans of moss they will be nice stock ready for potting separately by the end of the season.

Much the finest collection of plants of this section—i.e., *D. nobile* hybrid—I have seen were growing in a small span-roofed house with absolutely no fire heat from May onward, and as soon as the majority of the stems were well developed the house was thrown open all day long and all shading removed, only being closed when danger from early frost was apprehended. The small pieces I noted above made stems from 9 inches to a foot in length the first season after potting, and flowered abundantly the next. This is a far better method of propagating than division of the plants. The flowers of a good form of *D. Leechianum* (fig. 89, page 325) are 4 inches across, the sepal white tipped, with purple and feathered blotch of crimson appear on the lip.

Phaius Cooksoniæ.

The specimen sent by "Young Orchid Grower" represents a poor flower of *Phaius Cooksoniæ*, which though only exhibited for the first time about five years ago is already comparatively plentiful. It is a hybrid from a cross between *P. Humbloti* and *P. grandifolius*, and

was shown by Mr. W. Murray, gardener to Norman C. Cookson, Esq., Wylam-on-Tyne, in competition for a special prize that was offered by the Royal Horticultural Society for the best seedling Orchid. *P. Cooksoniæ* (fig. 90, page 325) received the premier award, and is particularly handsome. The sepals and petals are of a peculiar shade of buff, with flushings of rose. The lip is superb, being purplish rose at the outer portion and yellow mottled with brown in the throat.

Lælia majalis.

This must certainly be awarded first place among the Mexican species of the genus, its large, wide-opened blossoms being extremely showy, especially when a well-flowered specimen is seen. Unfortunately, many growers still persist in keeping it in heat and moisture all the year and complain as to its paucity of flowering. It is free enough if thoroughly ripened by exposure in summer, and the only fault is that in such circumstances it is apt to exhaust itself in a few years, the pseudo-bulb being small when compared with the superb blooms. A native of immense tracts of country, it is naturally variable, but every form of it is good.

Dendrobium**Brymerianum.**

The flowers of this delightful *Dendrobium* vary considerably in size, but, excepting the almost worthless *D. B. histrionicum*, all are excellent Orchids, the long flexuous fringe to the lip being a very attractive feature, as well as the bright yellow tint of the whole of the flower. Under the usual treatment it blossoms every season, though it cannot be described as a very floriferous species, but what is lacking in quantity is more than compensated in beauty. The roots are rather larger than the ordinary, and the compost may be rougher, and the pots a little larger than usual.

Leptotes bicolor.

This pretty species comes for identification. It is not much grown

nowadays, being far too small for the majority of orchidists, but it is a pleasing plant nevertheless. From the base of the cylindrical leaves the flower spike springs, each blossom being of two colours, as its name denotes—white on the outer segments, with a purple streak on the lip. It is not a vigorous plant, and should be grown in small baskets or on blocks in the intermediate house. It will not stand severe drying in winter, but must not be kept too wet, and it should always be very firmly fixed in position.

Varieties of Dendrobiums.

On more than one occasion recently I have had complaints from amateur growers that plants they have purchased in flower one season do not come up to their proper form the next. In some instances doubtless there is a reversion from a good form to a poor one, but this is usually in the case of a newly imported plant being sold in flower, as the next season's blossoms are often disappointing. But in others the fault is often in cultivation, and this is proved by the fact that from certain parts of the stem on *D. nobile* there are often good flowers, while on others they are smaller and less perfectly formed.

FIG. 88.—CATTLEYA INTERMEDIA FOWLER'S VARIETY.

They are of course undeveloped when the plant is introduced to heat in spring, and only the most favourably placed blossoms appear in the proper form. If the whole of the stem shows poor flowers then of course the plant is either of a bad form or it has been insufficiently ripened. Large stems of most species when carrying many flowers will usually have the best of these towards the top, the lower ones being smaller and less perfectly coloured, evidently owing to want of light or something that hinders their full development. At any rate it is unfair always to blame the nurseryman who supplies the plants.—H. R. R.

Gardening on Grass.

TIMES out of number fluent pens have written of the kaleidoscopic changes that have come about in the art of gardening during late years, and the consensus of opinion apparently favours the assumption that the march has ever been towards better things. The geometrical precision with which our forbears laid out their gardens has given place to a more pleasing informality. But in this very informality there lies an element of danger, for it may occasionally lead to a state of wild confusion which is by no means beautiful or natural. Even the most ardent advocates of informal gardening could not lend their support to a condition of affairs that is nothing more than a chaos.

There is, however, one form of free and natural gardening that appeals with irresistible force to all, and that the planting of bulbs in the grass of mounds, dells, wildernesses, and in pleasure gardens generally. It is a phase of gardening that has come to the fore with enormous strides, but which is still to all intents and purposes in its infancy. A few years back it was the exception rather than the rule for many bulbs to be found flowering in a grassy carpet, but now the position is practically reversed. From this it must not be inferred that the practice is a new one, for such is not the case; on the contrary a few of the more advanced cultivators have long since adopted it and sounded its praises on every available opportunity. Until recent years, however, the results of their efforts for the popularisation of one of the most charming phases of gardening were not particularly encouraging. Although the present day stage is such an advance, there still remains abundance of room for development and extension, and it is more than probable that this and other forms of informal gardening will, during the next two decades, attain to such a degree of excellence as will satisfy everyone.

In perhaps only one direction can grass gardening be carried to an unwarrantable length, and that is in planting on lawns. To such a practice there are several urgent objections. The chief beauty of a lawn lies in its unbroken surface, and whether this be level or undulating, it is spoiled immediately bulbs are planted here and there in it. To many people no portion of the garden has greater attractions than the lawns, with their perfect sward—a sward, we are told, such as cannot be excelled by that of any country in the world, and, indeed, is rarely equalled. It is an act of distinct vandalism to plant bulbs in this grass, although it certainly has been done, and that in places of no small pretensions. This is the more regrettable as it will, if persisted in, bring the utilisation of bulbs and plants in the grass into disrepute. Advocates of the system must therefore, in recommending extensive planting, guard against advising it in too general terms, but instead, specify either positions that are suitable or those which are unsuitable. As a broad principle, it might be laid down that no bulb or plant shall be grown on any piece of grass, large or small, that is supposed to be kept as a lawn. The writer can picture in his mind one lawn, of splendid proportions, that is completely spoiled as such by the square patch outside one of the windows of the mansion, and which the owner insisted should be planted with Daffodils.

Once the dividing line, which should not, as is sometimes the case, be in the form of an iron fence, between the lawns and the pleasure grounds has been passed grass gardening may begin in earnest. In practising this phase of horticulture many things have to be considered before success can be positively assured. The number and variety of the plants and bulbs at command must be determined, and then positions must be sought that are suitable, according to the shade lovers the essential protection, and to those which luxuriate in the full light the benefit of all the sun. Continue the walk and pass by an imperceptible transition from the pleasure gardens to the woodland walks beyond, and still the grass gardening must be continued with the difference that here our own native plants are real adornments, and the addition of bulbs and exotic plants will be simply

adding another delightful feature to a beautiful part of the demesne. In brief, every portion of the grounds, save the lawns, can be improved and beautified by the utilisation of plants and bulbs which for the most part can be readily procured.

The present is the best season of the year for enjoying the charms of the bulbs that rise from their grassy carpet, and many instances could be cited of particularly pleasing results that have been attained to. In the Royal Gardens, Kew, in several of the London and provincial parks, as well as in numerous private places, hundreds of thousands of bulbs have been planted, and the results are almost invariably satisfactory. True some places are more attractive than others, this being accounted for by the surroundings, and also by the taste of the planter, for even as there must be taste in arranging a dinner table, a conservatory or a flower garden, so must there be in planting bulbs in the grass of pleasure gardens. To crowd every square foot of ground with different bulbous roots, irrespective of kind or position, is not exercising the gentle art of gardening, but simply filling space, and is not at all likely to prove pleasing to those of refined tastes. Discrimination must be used here as elsewhere in the garden, or it is best left alone, and reliance placed on the trees and shrubs and the grass.

Opinions differ as to whether the planting should be in mixture or otherwise. For example, some growers adopt the system of planting Daffodils, Crocuses, Tulips, Snowdrops, and others *en masse*, and the benefit of a long season of flowering in one special place is claimed. The wisdom of this is doubtful, as generally speaking the formation of colonies, so to speak, is followed by the best results. Some places that are suitable for one kind are not for another, and therefore the planter is on safer ground when he avoids heterogeneous mixtures. The distinction can under some circumstances be made even more stringent in planting only one variety of a kind in each situation. There can be little doubt that this is the best method of all to follow, but it is not always feasible, as the outlay in stock is likely to be much greater. Two or three bulbs or plants, as the case may be, are seldom sufficient for a given position; indeed, a similar number of dozens will not always suffice, and it becomes necessary to make special purchases which with some varieties may be an easy matter, but with others is difficult on account of the expense.

In the majority of instances the question of ways and means is much more readily answered, for little or no stock is specially procured. One of the most beautiful examples of gardening on grass has been carried out without the outlay of a single penny, except for labour, on the part of the owner of the garden. Many thousands of bulbs are there planted, but not one was procured for this specific purpose. Thousands of plants, too, have been employed, but these have been propagated from existing stock, or have come from brother gardeners in the customary course of exchange. The gardener made it his hobby, and not only found intense delight in it himself, but gave equal pleasure to his employers as well as to the numerous visitors. All the bulbs planted have been grown in pots or boxes for the conservatory and for cutting purposes, and when the almost unique beauty of the grass gardening is seen it seems nothing short of sin to throw away one single bulb.

Such a rigid system as this, however, unquestionably has its disadvantages, except in establishments where several thousands of bulbs are potted annually. As a matter of fact it is preferable in any case to order specially for the purpose, particularly of Daffodils and Crocuses, of which excellent bulbs can be purchased at such low rates. All bulbs from pots that are not required for shrubbery or other borders can still go to the grass garden, while for the wilderness and woodland where masses are most effective advantage may be taken of the cheap stock that is purchased in bulk. With a view to keep quite abreast of the times many of our leading bulb merchants make special offers of Daffodils for culture on grass, for which purpose some varieties are rather better adapted than others. Tulips are not invariably satisfactory, but otherwise practically all hardy bulbs succeed, while the plants that are amenable to this form of culture are so well known as to render names quite superfluous.

Although it is not always done, planting should always be carried out by first removing the turf, improving the soil if necessary, planting carefully and relaying the turf. Sometimes a dibbler is used, but it is not by any means good practice, as the planting is never done properly, hence the bulbs are not nearly so likely to produce satisfactory flowers. Let the planting be done thoroughly, and it will usually be found that instead of deterioration in quality in subsequent years, there will be improvement with an almost certain increase in the number of bulbs. The after treatment is of the scantiest, for it simply consists of the avoidance of mowing until all leaves have died away; to mow the grass and green leaves on the score of tidiness is simply to court failure, as it is the perfect development and maturation of the foliage that govern the after condition of the bulbs and the quality of the flowers they will produce in the future.—F. ROWE.

Garden Stock in England.

THE conquest of this country by the Romans was the cause of the first impetus given to the cultivation of culinary luxuries in Great Britain, and the further subjugation of England by the Normans was attended with an accession of hitherto unknown treasures of vegetation, which gave to the ground a wider scope for industry, and to the vegetarian a more appetising set of courses. The first fruit novelty introduced into this country is supposed to be the Cherry. Lucullus originally brought it from Cerasus, a city of Cappadocia; he introduced it into Italy, and thence it was imported into Britain about the middle of the first century. In his "London Lickpenny" Lydgate, the poet monk of the sixteenth century, thus alludes to their sale in the street—

"Hot pescode own began to cry
Strawherys rype an cheryes in the ryse."

But though they had thus early attained to a coster popularity, it was not till the close of the seventeenth century that some inventive genius conceived the idea of hawking them on sticks to tempt the youngsters of the period.

The Pear has a very ancient history as a cultivated fruit in the gardens of the East, where it was highly valued for its refreshing and luscious qualities. It was brought into England with the Peach, Apricot, Quince, Almond, and Melon; those exquisite delicacies of fair ladies' taste were imported from Epirus, Carthage, Armenia, and Syria, and became established in Britain under the cultivation of the Romans. The Walnut and Mulberry, originally indigenous to Persia, were first planted in England about the middle of the sixteenth century, at which time, also, the Plum and the Nectarine, natives of Asia, were brought to our gardens by the Crusaders. Filberts and Apples that are now of such staple importance in our markets, were first imported from France, where the nuts took their name from Phillipert, monarch of that kingdom. As late as the reign of Henry VII. Apples were very scarce in England, and sold at prices not less than 2s. each, while from 8s. to 10s. were paid for a like quantity of Strawberries to that which we buy now in the season for 6d.

Red Roses were such luxuries that 3s. was a moderate price for a single bloom, and when we take into account the extra value of coin of the period, these charges indicate their value as novelties. In the same reign Lord Cromwell introduced the Perdrigon Plum, and Apricots and Artichokes were luxuries cultivated for Royal use only by Wolfe, the King's gardener. Clover Grass was unknown in these kingdoms till its introduction by Sir Richard Weston about the middle of the sixth century; and another worthy knight, Sir Anthony Ashley, by importing the Cabbage, earned a debt of gratitude from those who appreciate the appetising qualities of that vegetable.

FIG. 89.—DENDROBIUM LEECHIANUM. (See page 323.)

It was about 1524 that the Protestant Walloons brought over slips of the Hop plant from Artois, and cultivated it in Kent, and its first use in the brewing of beer caused a serious commotion among the

anti-adulteration agitators of the period. The following old distich marks the time of its birth in England:—

"Hops, Reformation, bays, and beer,
Came into England all in one year."

Up to the end of the sixteenth century some of the most important vegetables were unknown to English taste, excepting as preserves

FIG. 90.—PHAIUS COOKSONII. (See page 323.)

salted down. Catherine of Arragon, who had been accustomed to the use of new green meat in her native country, was constrained to send for her daily dish of salad by special messengers to Holland and Flanders; such a long journey to market for a few vegetables is surely matter for curiosity and amusement to the visitor of the present day to Covent Garden Market. Throughout the reign of Henry VIII, a Cabbage from Holland was regarded as a valuable present, and during this dearth of garden table stuff Hull pushed a considerable trade in Cabbages and Onions. As late as 1595 a sum equal to 20s. was paid in that port for six Cabbages by the purveyor of the Clifford family. It was about this time, says the present writer in the "Standard," that the English appetite was whetted for the charms of the Apricot, Gooseberry, Pippin, and Artichoke, and the Currant bush, originally brought from Zante, was then a novelty. It was also towards the end of the sixteenth century that Cardinal Pole set the first Fig tree in the garden of Lambeth Palace.

In the reign of Elizabeth, Edmund Grindal, afterwards Archbishop of Canterbury, transplanted the Tamerisk to England, and it is to the Carew family that the country owes the early introduction of the Orange tree. The first China Orange which appeared in Europe, was sent as a present to Conde Mellor, Prime Minister to the King of Portugal; but of the whole case sent to Lisbon one tree only survived to be the parent of the Orange trees of Europe. Beddington, in Surrey, was their English nursery, under the fostering care of Sir Francis Carew; they had been growing there in open ground, under a movable covert, for more than a century, till they all perished in the great frost of 1739-40.

It is impossible to exaggerate the importance of the benefits bestowed on household economy and industry by the exiles of the Reformation, who sought England as a haven of refuge. On the arrival of the Huguenots in Spitalfields they started the horticultural societies, that quickly provided the country with such luxuries as Cauliflowers, Turnips, Carrots, and Parsnips. Those refugees who settled at Portarlington, in Ireland, were the first to familiarise the British public with the excellencies of the Jargonelle Pear and the black Walnut; and when the Flemings selected Sandwich as their adopted home, their first important work was to turn the land to the best account by flower and market gardening. The celebrated Canary Grass was until then an unknown object in our fields and lanes, and the reputation of the "Sandwich Celery" became celebrated throughout the kingdom. "Common knowledge" is responsible for many mistakes, amongst which Sir Walter Raleigh is credited with

having been the first to cultivate the Potato for the English dinner table. As a matter of fact, it is to Admiral Sir John Hawkins, the great Elizabethan navigator, that we owe gratitude for the first English grown specimen of that important tuber.

The Royal exiles of the Restoration brought with them, on their return to England, amongst other accessories of the kitchen garden, the Bean, Pea, Lettuce, and Asparagus, which were originally grown in the Island of Cos, near Rhodes, in the Mediterranean. Haricots or French Beans were originally native to the East Indies, and with regard to the common Broad Bean, its origin is lost in obscurity, for it is not found in any part of the globe in a wild state. The Tomato, that has been cultivated so largely in England of late years, is exclusively of Peruvian origin, neither it nor the Capsicum being known in Europe till after the discovery of America. Spinach found its way here in the first instance from Western Asia, but the most valuable species has been imported from New Zealand during the past few years. Asparagus and Beetroot originally found their way into our island from the sunny fields of Italy. The discovery of America produced for the gardens of England about 3000 novel varieties of vegetation, South Africa close on 2000, which, combined with constantly increasing additions from Australia and other countries, did fair to endow us with a vast cosmopolitan flora. Many of these will in course of time become thoroughly acclimatised, and should our civilization, like that of Rome, ever suffer an eclipse, future scientists will dispute much more regarding "What are indigenous British plants?" in the year 5000 A.D. than we do about the original habitat of the Apple, the Pear, the Wheat, and the Plum.

Dwarf Phloxes.

It is not many years since the species and varieties figuring under the head of Alpine Phloxes were comparatively few in number, and while the former remain about the same to-day, the latter have increased considerably, bringing new and pleasing shades of colour, while for free growing and flowering they are all that can be desired. These latter remarks apply more especially to the varieties of setacea which enrich our gardens in the spring to some considerable extent. The whole of the varieties of setacea, as well as frondosa, nivalis, and Nelsoni, form dense prostrate cushions, which in May and June are completely hidden by the numbers of flowers produced. Nothing can surpass them for effect in the spring garden, and where this is indulged in to any extent some of these Phloxes should be among the number.

For the convenience of those desirous of securing the most distinct varieties, I will give what I regard as the best, all points considered: atro-purpurea, dark rosy purple, very free and a good doer; The Bride, pure white, with a ring of scarlet spots in the centre, a telling variety, habit very compact, and an abundant bloomer; compacta well bears out its name, and produces rose-coloured flowers freely. Vivid in point of colour is the most effective; it does not produce flowers as large as some, but is remarkable for freedom, while for colour it stands alone; its rigid tufts, studded with rosy scarlet flowers with deeper centre, render it very conspicuous. The foregoing I consider the best and most distinct of the forms of setacea, apart from which there are several which cannot be omitted. Among these Nelsoni stands first, and is covered with pure white masses of bloom, a most charming plant; and frondosa, with rosy pink flowers. All these are very similar in general aspect, quite hardy, and most effective.

But what I regard as the gem of all the Alpine Phloxes is *P. amœna*. It is an excellent plant for effect, and so continuous a bloomer, according to the season, it flowering in April or very early in May, and continues a long time in perfection. I have had this one in flower for six months, and had as fine flowers in October as in May; but to get this result it should be divided as soon as it has ceased flowering, and planted in good rich soil. Attend to watering and so forth, it will speedily recover, and show signs of flowering again. Its full height is 6 inches; the colour of the flowers is a bright pleasing pink, and to see a bed some 40 feet long carpeted with this lovely plant in full flower, is one of the prettiest sights in spring. The only other that calls for mention now is that usually sold as *verna*, but which correctly is *reptans*. It has also been distributed under the name *stolonifera*, but this species has bluish or slate-coloured flowers, while *verna* (*reptans*) has reddish purple flowers. Both plants, however—i.e., *stolonifera* and *reptans*—possess the same habit, hence the confusion probably.

All the varieties of setacea and their allies may be increased by division either in autumn or spring after flowering. Cuttings of all these taken when about 2 inches long—that is, of new growth and with a heel attached, root readily in moist sandy soil, in hand-lights or frames kept close and shaded. *Amœna* may be had in abundance by division after flowering in May, while *reptans* will root readily if the runners are pegged on the surface of the soil, and may also be increased by division.

Every person who takes an interest in the cultivation of these plants should, I consider, take an interest in making the best possible display of them also. By this I mean that they ought not to be content by merely purchasing a plant and letting it do its best. That is not gardening in its truest motives, nor is it likely that the best

results will be forthcoming for such scanty pains. Let all cultivators make the most of the space at command, and few plants form a better starting point than these Phloxes. An amateur can buy one plant, and in three years it may make a good tuft, but if he had put in say fifty cuttings each year in the manner I have described above, and only succeeded in rooting half of them, and potted them singly in small pots, what a grand stock of such he may possess! But amateurs will wonder of what service such a stock may be to themselves, but I will explain. These Alpine Phloxes require to be seen in large spreading masses several feet across, and to quickly obtain these handsome floral carpets they should be increased freely. Established in small pots, and planted out about 6 or 8 inches apart each way, they would soon form a mass of colour such as is rarely seen, and make the garden a perfect paradise.—FLOWER GARDENER.

Notes on Figs.

EARLIEST FORCED IN POTS.—The small but very acceptable Early Violet and St. John's Figs are now being succeeded by Pingo de Mel, White Marseilles, and Brown Turkey. To secure perfect ripening and high quality, watering should be gradually reduced and syringing over the trees must cease, but trees swelling their fruit should be assisted with weak liquid manure twice a week and the foliage be kept clean by syringing at closing time. A temperature of 60° to 65° at night, 70° to 75° by day, advancing to 80° or 85° from sun heat, is suitable, closing so as to increase to 90°, but air must be afterwards admitted to allow the pent-up moisture to escape and prevent the deposition of moisture on the fruit, which settling on the apex is apt to cause decay. This should be avoided by a circulation of rather warm and moderately dry air.

EARLY FORCED PLANTED-OUT FIGS.—Trees started about the new year have the fruit advanced in swelling, and a mulching of sweet decayed manure about an inch thick is of immense service in encouraging surface roots and supplying nourishment not likely to induce grossness. Such mulching, if kept in a moist but not constantly saturated state, and added to from time to time, will be full of active feeders by the time the trees need most assistance, in order to perfect their crops; and some substantial chemical food every three or four weeks, or more distantly according to requirements, will, other conditions being favourable, secure sturdy growth and good results in the first and second crops. Trees in borders of limited extent, and those of short-jointed fruitful habit, will require copious supplies of water or liquid manure. Syringing may be practised twice a day in bright weather, occasionally in dull, maintaining a genial condition of the atmosphere by damping.

During favourable weather the ventilation should be free, with the object of securing stout growth, and thick, healthy foliage. Care ought to be taken to admit all the light possible, duly attending to pinching the growths, rubbing off the superfluous, and thinning out all the overcrowded shoots. The temperature should be maintained at 60° to 65° at night, 70° to 75° by day, advancing to 80° or 85° from sun heat, closing so as to run up to 90° on fine afternoons, but admitting a little air before nightfall, as pent up moisture is deposited on the foliage and fruit during the night, and favours fungoid pests.

SUCCESSIONAL TREES.—Trees started during February or early in March will require attention in disbudding or thinning the growths, regulating the terminal and successional shoots, and stopping the spurs at the fifth leaf. In order to secure a good and certain swelling in the first crop fruit, it is excellent practice to pinch the growths somewhat closely, or to three or four good leaves, and afterwards reduce them by disbudding, so as to prevent overcrowding, repeating the stopping, if necessary, at the fifth leaf. It is not advisable to bring the trees on too rapidly in the early stages of growth, 55° to 60° at night, and 65° by day, advancing to 70° to 75° from sun, with moderate ventilation, and above admitting abundance of air, as it is very important that the foliage be of good substance. When the trees are in full leaf the night temperature should be maintained at 60° to 65°, 70° by day, allowing a rise to 80° or 85° from sun heat, closing early with abundance of moisture.

LATE OR UNHEATED HOUSES.—The trees having had attention in thinning the least fruitful growths and the old and bare, so as to afford space for the successional, it is desirable to allow the shoots for bearing to grow somewhat loosely with their points to the light. Stopping must play an important part in cool houses. Pinch at the fourth or fifth joint on the young wood, which will assist the swelling of the fruit and induce the trees to break and produce short-jointed wood from the base of those in bearing, but do not allow more shoots to remain than can have full exposure to light, reducing them by timely attention to disbudding. Ventilate freely at and above 50°, advancing to 65° from sun heat. The border should be brought into a moist condition if dry, afterwards mulch lightly with short manure. Figs, however, in unheated houses do not require nearly so much moisture as those in heated structures, but an occasional damping will be necessary to maintain a genial condition of the atmosphere, ventilating freely on all favourable occasions, especially in the early part of fine days, so as to secure sturdy, short-jointed wood and well developed leathery foliage.—GROWER.

NOTES & NOTICES

Recent Weather in London.—The weather during the Easter holidays was somewhat changeable, but must be considered generally satisfactory. Both Good Friday (except for the gale of wind) and Saturday were fine, as also was Easter Sunday, except for a slight shower early in the evening. On each of these days the sun shone gloriously, and the wind had not the keenness of a few days ago. Monday was bright with slight showers at intervals; indeed, it was a typical April day, as described in the phrase "smiles and tears," as indeed was Tuesday also. On Wednesday it was very fine and warm.

Weather in the North.—Very high westerly and northerly winds have prevailed during almost the whole of the past week, and a good deal of rain has fallen in heavy showers. Sunday was very boisterous and wet, as was also the earlier part of Monday, but the evening of that day promised more settled weather.—B. D., *S. Perthshire*.

The Land of Daffodils.—Daffodils are being sent away from the South Lincolnshire towns in great quantities, and hundreds of women and young people are bunching the flowers. Despite the bad weather, there has been quite as much bloom sent to London and other centres this season as last. From the Spalding district, where the flowers are very extensively cultivated, last week 25 tons were despatched, 7 tons going away on Good Friday for use in the decoration of churches for Easter Sunday.

Recreation Ground for Bromley by Bow.—The Bromley Recreation Ground of nearly 1½ acre, purchased and laid out by the County Council at a total cost of £6780, was opened recently by Mr. B. Cooper, L.C.C., who said that after waiting many years and contributing much to the parks and open spaces in other parts of London, Bromley had become possessed of a lung. Bromley was one of the most densely crowded portions of the metropolis, where ground could not be bought at a low rate, but he felt sure that the residents would appreciate the outlay of the London County Council in providing such a charming space.

Messrs. T. S. Ware, Ltd.—For many years the business founded by Mr. T. S. Ware, and now being conducted as a limited liability company, has had its home at Tottenham, whence have been despatched many hundreds of thousands of hardy plants, for which the nursery had such an enviable reputation. So extensive and varied was the collection, that it was quite impossible for anyone to visit the Tottenham nurseries without finding something of interest in flower. But the old order changeth, and the headquarters of the firm have gone to Feltham. It was found necessary to move, and this position in Middlesex was chosen. Hardy plant lovers must hereafter, when they want to visit "Ware's," travel via the London and South-Western Railway from Waterloo, instead of from Liverpool Street as has previously been the case.

The Royal Gardeners' Orphan Fund.—Mr. Brian Wynne, of 8, Danes Inn, Strand, London, the secretary, desires us to intimate that the annual dinner of this most meritorious society will take place on Tuesday, May 8th, at the Café Monico, Piccadilly Circus. The objects of the fund are:—To make allowances or grants of money to aid in the maintenance and education of the orphans of gardeners, foremen in public, private and market gardens, and the managers and departmental foremen in nursery and seed establishments. By means of the fund eighty-five fatherless children are this year (1900) being assisted at the rate of 5s. per week until they attain the age of fourteen years, and who, with the sanction of the Executive Committee, may be placed with relatives or other responsible persons, acting as guardians. The committee also has power to grant a sum not exceeding £10 towards apprenticing or otherwise promoting the start in life of any orphan who may be eligible for such assistance; and to make arrangements for placing children elected to the benefits of the fund, either with carefully selected foster parents as cottage boarders, or with the master or mistress of a school or institution, from whom satisfactory security is required for the proper discharge of their duties.

Royal Horticultural Society.—The next Fruit and Flower Show of the Royal Horticultural Society will be held on Tuesday, April 24th, in the Drill Hall, James Street, Westminster, in connection with which the National Auricula and Primula Society will hold its annual show, 1 to 5 p.m. A lecture on "The Cultivation of the Narcissus" will be given by the Rev. S. Eugène Bourne, M.A., at three o'clock.

The Journal of the Royal Horticultural Society.—Volume xxiv. of this publication, which has just reached us, is undoubtedly one of the most excellent of the series. It embodies an exhaustive report of the Hybrid Conference which was held under the auspices of the Royal Horticultural Society in July of last year. The excellent introductory address of Dr. Masters, together with the complete text of the several papers prepared by experts, and a list of the principal plants exhibited are given, and form a most valuable addition to the not over-abundant authoritative literature on hybrids. To those specially interested in hybridisation the work will become a necessity; while to others it must prove interesting as well as instructive. The price to non-Fellows is 7s. 6d., and it may be obtained from the secretary R.H.S., 117, Victoria Street, London, S.W.

Royal Botanic Society.—At a recent meeting of the Royal Botanic Society the chairman, Mr. C. Brinsley Marlay, drew attention to some Marie Louise Violets grown in Ireland, and remarkable for their size, fragrance, and colour. He thought it would be of interest if he drew attention to the natural advantages Ireland had for growing plants which liked a limestone soil, and he had often been struck with the extreme delicacy of scent and brilliancy of colour of many plants growing in his garden in Ireland as compared with similar plants grown in England. The absence of sunshine during the summer months owing to the clouds prevented fruit and berries from ripening to the same extent or having the same colour as in England and Germany, but for many herbaceous plants there was no better soil than was met with in the neighbourhood of Dublin between the seashore and the mountains.

Kingston Chrysanthemum Society.—The annual show of this old society for the current year, and it will be its twenty-fourth, will be held as usual in the large Drill Hall on November 6th and 7th. Last year the executive avoided clashing with the first day of the National Society's show, but no one seemed to thank them for it. This year, also, there are one or two immediate local shows that it is felt to be more important not to be in conflict with. The schedule has been thoroughly revised, and whilst the great open class for cut flowers has been omitted, other classes for gardeners, likely to lead to greater competition, have been included. We believe the schedule of prizes, in slip form, is ready, and can be had on application to the new secretary, Mr. W. Hayward, Fife Road, whilst the complete schedule will be issued later.

Royal Agricultural Society.—We are informed that the special committee appointed to consider the question of sites for future shows, in presenting its report recommended that in place of a show in or near a different town each year, it would be much more economical to hold the show in some permanent locality, preferably in the centre of England, which would be convenient for railway access from all parts of the country. The report of the committee was fully considered, but the proposal for its adoption was opposed by Mr. Martin Sutton, on the ground that the council should not make such a drastic change without being sure that they were in touch with their *clientèle*. Mr. Sutton's resolution, however, was ultimately withdrawn, and the committee reappointed, with a view to selecting a suitable site for a permanent show ground.

Mount Vesuvius and Vegetation.—The inhabitants of the district of Somma Vesuviana, on the northern slopes of Vesuvius, writes the Rome correspondent of the "Morning Post," have just had an unpleasant reminder of the properties of the mountain on which they dwell. On ordinary calm days the head of Vesuvius is adorned by a plume of dark smoke, which, when the wind blows from the south laden with moisture, is carried northwards over the slopes of the mountain. During the last long spell of south wind it rained heavily without interruption. The rain in passing through the sulphurous smoke became impregnated with caustic salts, which have destroyed the flowers and young buds on all the trees, and have ruined all the young plants. The Vines alone escaped damage, because, on account of the cold season, their buds are still in a backward condition. The phenomenon is not new, though it is extremely rare.

Gardening Appointment.—Mr. G. Tyler, for the past ten years gardener to C. A. Jones, Esq., Bron Hendre, Carnarvon, South Wales, and late of Craig-y-Nos Castle, Swansea, has been engaged as head gardener to Mrs. J. W. Jones, Plas-y-Bryn, near Carnarvon.

Honouring Miss Eleanor A. Ormerod.—Miss Eleanor Ormerod, the eminent entomologist, who has done so much valuable work in bringing to the knowledge of agriculturists the life history of the several pests which afflict their crops, received the degree of LL.D. at the spring graduation assembly of Edinburgh University on Saturday. Professor Sir Ludovic Grant observed of Miss Ormerod that their roll of honorary graduates in law now for the first time contained the name of a lady. Miss Ormerod's labours had been crowned with such success that she was entitled to be hailed as the protectress of agriculture and the fruits of the earth.

Dollis Hill Estate.—The Select Committee of the House of Commons, of which Sir William Houldsworth is chairman, yesterday afternoon passed the preamble of the General Powers Bill of the London County Council, which includes provisions enabling the Council and the Hampstead Vestry to contribute to the acquisition of the Dollis Hill estate for the purpose of a recreation ground. The only opposed provision of the Bill was one to enable certain land at Battersea, now used as allotment ground, to be appropriated in part as an open space, and in part for the erection of artisans' dwellings. The Committee, in giving its decision on this point, expressed a hope that the County Council and the Vestry would give the allotment holders, and especially the older ones, as much consideration as the circumstances might justify, and thought it might trust them to do this.

Soil Samples.—We have received a catalogue of the first 4000 samples in the soil collection of the United States Department of Agriculture, prepared by Mr. Wilton Witney, chief of Division of Soils. To all interested in soil investigations this publication will be a useful and suggestive work of reference. Not only does the collection contain specimens of soils from the chief geological formations of the United States, it also includes samples from many of the important agricultural districts, and likewise special collections of Wheat soils, and Tobacco soils, from all parts of the world. Remarks are made concerning the collection of specimens, their arrangement and classification, and it is stated that sets of representative soils are arranged in boxes, to be distributed to agricultural colleges and experiment stations, with explanatory text regarding their origin, chemical and physical peculiarities. One object in publishing the catalogue is to suggest exchanges with institutions in other countries.—("Nature.")

Useful Hints by an Octogenarian.—That the occupation of gardening in association with prudent habits of life is conducive to longevity and activity, the frequent contributions to these columns by "D. Deal," and an occasional jaunty "screed," as he terms it, by Mr. Robert Fenn, afford good testimony. There is, however, another octogenarian in the gardening community, the bearer of a familiar and much respected name—James Dobbie, the founder of the enterprising firm that worthily bears his name at Rothesay. Mr. James Dobbie was for some years a gardener and a good one—a deep thinker and thorough worker. Though eighty-three years of age his eye is still clear, his hand firm, and his arm strong enough to enable him to enjoy a "good day's work with the spade" in his cherished garden at Tor Castle, Craigmere, Isle of Bute. Thinking some records of his fifty-five years' practical experience might be useful, he has embodied them in a sixpenny pamphlet of thirty-two pages. He treats of the importance of shelter for almost everything that grows in garden and field. He seems to have been a pioneer in supporting fruits in nets for their longer retention on trees, and the consequent gain in size and weight for exhibition, as he also was of raising Onions under glass and growing large bulbs thirty-three years ago. He tells of growing Leeks in tubes for winning prizes, also of his method and success with various other crops. Nor does he forget the enemies that beset his path—the underground pests, such as wireworms and millipedes; the night prowlers—slugs and snails; the leaf eaters and sap suckers—caterpillars and aphides; the "rusts" of Parsnips and Parsley. He has a word about them all, and explains his easy methods of conquering them. Mr. Dobbie, in short, covers a wide field in concise form with the object of being helpful, and his unpretentious pamphlet may be fairly described as a veritable *multum in parvo*.

French Colonial Garden.—The Colonial Garden established at Vincennes last July is rendering important service to the French Colonies. M. Dybowski, the Director, informed an interviewer that he was at present engaged in studying the Ko-sam plant, which had been found to be a marvellous remedy against the dysentery prevalent in hot countries. A discovery made at the garden was that *Eucomia almoides* contains 28 per cent. of guttapercha. Plants have been sent to Tonquin, Annam, and North Africa, and it is confidently hoped that very important results will be attained. Incidentally M. Dybowski found that the bark of Indiarubber trees contains 5 per cent. more rubber than the leaves and branches. All the Governors of the French rubber-producing Colonies have been informed of the fact. The bark has hitherto been thrown away.

London at Play.—The first bank holiday of the year passed off pleasantly and safely. London's millions had a full day of play and pleasure. A hasty bird's-eye view of London making holiday is presented by the following figures:—Kew Gardens, 70,000; Crystal Palace, about, 101,651; Alexandra Palace, 63,000; Hampton Court 23,000; Wembley Park, 8,500; Hampstead Heath, 110,000; Epping Forest, 120,000; Waterlow Park, 25,000; Highgate Woods, 30,000; Zoological Gardens, 33,883. It was a truly April day. Sometimes it was raining, sometimes the sun was shining brilliantly, and sometimes both kinds of weather synchronised. The showers were heavy while they lasted, but the sun had by far the best of the encounter upon the whole, and the great, good-humoured crowds everywhere looked as if they had no fault to find with the weather or anything else.

A National Rose Day.—Respecting the proposal to establish a National Rose Day, "F. R. H. S." writes as follows in the "Surrey Comet":—"Seeing St. George is a comparatively unknown quantity in English sentiment, and that Queen Victoria is a very practical factor in sentiment and patriotism, the saint should be ignored in the future as in the past, and so noble a woman and queen as is her Majesty be the subject of the proposed Rose celebration. It fortunately happens that the anniversary of Queen Victoria's coronation, which took place in 1838, falls on June 28th, and right in the midst of our Rose season of flowering. It is a time of the year when Roses are everywhere, and can be had by the humblest as well as by the richest. The Rose is peculiarly a British flower, as our woods and hedge-rows show, and from these native species have come most of the beautiful varieties we grow in our gardens. There would also be particular charm in this universal adoption of the Rose as a floral emblem in honour of our illustrious Queen, that far back in English history the wars of the Roses, red and white, showed how bitter racial animosity divided England, and now in wearing on June 28th Roses of all colours would show how the old divisions and hatreds had been healed in this mode of celebration of Queen Victoria's reign. We must not forget also that the present reign is the longest known in English history, and it has proved to be in very many ways by far the greatest and most progressive era of all time. Long after the Queen has been gathered to her fathers the Victorian era will be regarded with wonder and veneration. Were it universally agreed to establish a Victorian Rose Day on June 28th in this and succeeding years there can be little doubt that it would be universally observed.

The weather during the week has been generally dull with south-westerly gales, which were unusually strong on the 13th inst.

The New Chiswick.

WHATEVER may be the nature of the reception given to the proposals of the Council of the R.H.S. at the Fellows' meeting on Wednesday next, and it is hoped that the matter will be discussed on its merits, and not on any local or personal grounds, it may interest some Fellows to learn that whilst the nearest railway station to the proposed site for the new gardens at Limsfield, Oxted, is twenty-one miles from London, yet trains run there very frequently and rapidly. Thus, besides some half dozen from Charing Cross and Cannon Street daily by South Eastern Railway, there are about twenty-four each way daily from Victoria and London Bridge on the London, Brighton, and South Coast Railway. A train is timed to leave Victoria at 10.40, reaching Oxted at 11.27, another at 11.15, arriving at Oxted at 11.52, only thirty-seven minutes' run; another leaves Victoria at 1.30 P.M. and arrives at Oxted at 2.22. These are fairly fast trains, but even the stopping trains do the run in all cases under an hour. The return trains are also quick. This will enable Fellows to understand that whilst the ride is a little longer than has been the rail ride to Chiswick, it is not one that occupies much more time, and is through beautiful country. The Limsfield site is also in a most charming district, and a visit to it in due course will be amply repaid by the delightful air and views obtainable. It is hoped that should the site be fixed upon by the meeting in accordance with the desires of the Council, that the latter body will not only endeavour to secure special cheap rates of transit to and from London for Fellows, but also will do the same with the proprietor of the livery stables adjoining Oxted Station. —A. F.

The Old Chiswick.

IN writing under the now familiar title of the "New Chiswick" on page 307, a correspondent has some pertinent remarks on the historic old garden that would now seem to be doomed. Knowing something about this garden, I cannot help feeling sorry on observing a tone almost of rejoicing by one or two writers that its end appears to be so nearly approaching. If its abandonment is really necessary, I am one of those, and there must be many, who can only regard the fact with extreme regret.

It seems to be taken for granted, though I do not remember seeing any explicit statement to that effect, that the lease of the garden from the Duke of Devonshire, now shortly expiring, cannot be renewed on something like the existing terms. If that is so it would seem desirable that it be made clear, as it would do something to reconcile those who cannot view the abandonment of the famous old garden with complacency to the inevitable departure.

If the great change is simply based on the alleged "exhaustion" of the land it may be fairly asked if all has been done that might have been done, or that could be done to restore its condition? That it has been badly treated in the past can scarcely be disputed. Not so many years ago practically no manure was supplied, and the late superintendent had to trench a little deeper and deeper to get a film of fresh soil to support the crops as well as he could. That was before the present Council was responsible for its condition, and they certainly have in some respects improved the garden; still they have not been over-generous in the labour supply, and perhaps more substantial work has been expected from the "students" than has been done by them.

But accepting all the drawbacks, including "exhaustion," fogs, smoke, and everything else, it can scarcely be said that the old garden has militated against the prosperity of the society. In no period has there been such a great increase in Fellows as during the later years of Chiswick, and it would be interesting to know how many of these are residents in the locality, also if these are expected to remain supporters of the society when the garden is relinquished.

But while Chiswick has strengthened rather than weakened the society in that respect, the great accretion of Fellows has been mainly due to the Temple Shows and London meetings. When this fact is remembered, the opinion of the correspondent on the page above referred to seems not unnatural—namely, that a proper hall in London would be more in accordance with the wishes of the Fellows as a body than any new garden which very few indeed of them could visit.

That a suitable London building is very greatly desirable no one can deny. The president rarely makes a speech without admitting this, but leaves the question by what seems to have become habitual with him, in casting a bait for a millionaire. If Sir Trevor has some good reason to expect a "catch" his treatment of the subject is understandable.

The present building was only regarded as a makeshift, and it is likely to become more and more unsuitable. Then the time may come when there may be a check in the influx of Fellows, and at least the hundreds who have joined through the London gatherings are entitled to a large share of consideration.

Large numbers of these cannot be expected to care for a large and costly garden two or three miles from a station in Surrey, nor are they likely to be impressed with the high-sounding title of a "School of Horticulture," or to be convinced that the benefit resulting from it will justify the outlay involved. In a matter of such great importance, of leaving historic old Chiswick and embarking on a new enterprise, which, so far as the general body of the Fellows know, is of a speculative character, it would surely not be unreasonable to explain the whole scheme fully at a preliminary meeting, and afford time for the project to be considered in all its bearings before a final decision is arrived at. A month would not be too long for this. The matter is one of too great moment to be settled in a perfunctory way at a formal meeting at which, perhaps, not more than 1 or 2 per cent. of the Fellows may be able to attend.—A LOCAL FELLOW.

A National School of Horticulture.

"ANOTHER FELLOW" seems to think that the providing of a school of horticulture is work for the Government. As there are in Great Britain so many industries, all of which would equally clamour for a national school did the Government promote one specially for horticulture, we can well imagine the confusion that would result. If horticulture needs a national school, then I cannot conceive of more fitting work for the Royal Horticultural Society, established, it should not be forgotten, by Royal Charter, that it might be the leader in horticultural work in the kingdom. The question really is less whether what is proposed is the proper work and duty of the R.H.S., for that body has obligations to horticulture that are illimitable, yet bounded by capacity; but whether such a national school of horticulture is needed. Now something of the kind has long been asked for in many directions. Possibly even those who have thus asked for such an institution may not have thought out fully the possibilities or constitution of the same, but I cannot conceive of anybody more entitled to originate and assist in the conduct of such an institution than the Royal Horticultural Society.

Donbtless many persons have leaped to the conclusion that it is the council's intention to organise such a school alone; that is of course a great error. The notice of the meeting to be held in Victoria Street on the 25th clearly states that what is purposed in relation to a national school is so intended in co-operation with important public bodies, even including the Government Department of Agriculture and County Councils, and whilst the R.H.S. may obtain great advantages from the formation of such a school, the pecuniary obligations involved may be light. What seems possible is that with the aid of these various outside and important authorities there may be established at Limsfield the finest horticultural school in the world. And if that should result it will be much to rejoice over.

I hope, in relation to such a school, no one imagines that a few years' tuition and study at it can turn out capable gardeners. That would be too absurd. No matter how clever or capable a young man may be, he must, in addition to his college course, have several years' experience in market establishments, nurseries, and private gardens to make him fully qualified to undertake any responsible charge. But it should be evident that any youth who can have some three or four years' training at such a national school should possess elementary advantages far in excess of those a youth can obtain outside of such a school. I some time since showed how greatly we needed well-trained fruit growers; indeed, it is in connection with market culture of fruit and allied products that training is most needed, as just now there are far more demands for qualified youths in this direction than in private gardening.

Practically private gardening is an overdone vocation. It is far too crowded as it is with excellent and wretchedly paid men. It is in the direction of helping horticulture to become a national industry that we need the proposed school. But it must be a very practical school. Some such of so-called collegiate status have been wretched failures where pupils have had an easy life, wasting valuable time in sports and pastimes, and in performing trivial work perfunctorily. At any national school students must be compelled to realise that work is for them a grim reality. In that respect a heavy responsibility would rest on the authorities.—A. D.

Apple Norfolk "Biffin."

IN your issue of March 29th I see a paragraph on the Norfolk Biffin, pronounced as spelt. I have known the Apple over sixty years, and never heard it called Beefing by a Norfolk man. It is not now much grown, as cooks do not like it, and it is useless as a cider Apple. It is a grand Apple for drying, to be used as dessert. Fifty or sixty years ago it was in great demand for that purpose, and fine samples fetched a high price. I grow them for that purpose now. In "Nuttall's Dictionary," 1891, page 69, it is spelt Biffin.—H. T. H.

Cinerarias at Impney.

I ENCLOSE a photograph of Cinerarias in flower at Impney, the residence of John Corbett, Esq., near Droitwich. The plants have been grown from seeds supplied by Messrs. Sutton & Sons, and the photograph shows that the "strain" is equal to the cultivation. The plants (fig. 91) are dwarf and robust, the latter quality only being present in Cinerarias when they have been well nourished and kept free from aphids. The heads of flowers range from 18 inches to 30 inches across, and most of the individual blooms are 3 inches in diameter. The colours vary from white to deep purple, with intermediate shades of mauve, pink, deep crimson, and blue.

too stiff and formal in habit to be considered truly artistic, yet its masses of colour cannot be well replaced at the same cost of labour and money.

Cinerarias, as their leaves suggest, delight in light and rich soil, abundance of water without stagnation, and a position where they can obtain plenty of light and fresh air, and a temperature between 40° and 50° in winter, and 50° to 60° in summer. They are usually ruined in their youth through an insufficiency of food and water, which causes a premature formation of flowers, then good-bye to hope of fine plants. Young plants should be placed in larger pots before they become in the smallest degree root-bound, and this ought to be done from time to time until the plants are in the pots in which they are intended to flower. The same remarks are equally appropriate to most flowering plants under pot culture.—J. UDALE.

FIG. 91.—CINERARIAS AT IMPNEY.

The photograph shows the Cinerarias growing in two divisions of the plant houses. The range is span-roofed, 100 feet long by 12 feet wide, and is in three divisions, the third being occupied chiefly by Orchids, a class of plants to which Mr. Corbett has recently become partial, and is represented at Impney at present by healthy examples of Dendrobiums, Cattleyas, Laelias, Cypripediums, and Odontoglossums.

Cinerarias are very easily grown, given food, water, light, cleanliness, and coolness; but if one of those factors be absent the presence of the remaining four will not insure success. Mr. Jordan and his clever and painstaking foreman, Mr. G. Giles, have provided the five essential conditions, and have achieved a well-deserved triumph. The notes and articles which have recently appeared in the *Journal of Horticulture* prove that there is a re-awakening in regard to the value of the Cineraria as a decorative flowering plant; and although I think it is

Anthuriums.

THE spathes of Anthuriums varying in colour from pure white to deep crimson make them remarkably showy and worthy of attention from all lovers of plants. When a collection is grown the plants produce when carrying their spathes an appearance at once novel and attractive, and they serve the gardener many a good turn for various decorative purposes. Of course it is not given to every gardener to have a stock such as that so admirably grown by Mr. W. Bain for Sir Trevor Lawrence, Bart., V.M.H., Burford Lodge, Dorking, but they are always valuable. At Burford one may find practically all the finest Anthuriums in cultivation, and their beauty has been demonstrated over and over again when the plants have been exhibited at the Drill Hall. Some produce immense spathes of self colours, and others are most chastely

Fig. 92.—ANTHURIUMS

spotted and blotched with brilliant rose on a pure white ground or the reverse (fig. 92), while still more have small spathes with gorgeous colour and floriferousness as their chief recommendations.

Apart, however, from the species and varieties that are cultivated for the beauty of their spathes we have others with noble foliage, and of which *Anthurium Veitchi* may be mentioned as typical. This is undoubtedly, when well grown, one of the handsomest large-leaved plants in cultivation. These, however, must have abundance of room to show off their good points, and perhaps this is one reason why plants are not more commonly seen in gardens. Grown in large tubs standing in some conspicuous position they never fail to attract attention from everyone, and as a rule they are much admired. Until the plants of the fine-foliaged *Anthuriums* have attained to considerable size annual repotting is desirable, using a mixture largely composed of sphagnum moss and fibrous peat. When, however, the plants are in large receptacles this practice is not generally adopted owing to the labour entailed, and it is not really necessary provided the pots or tubs were efficiently drained at the outset, and that great care is always exercised in watering.

Reverting to those which are cultivated for their spathes, it may safely be said that *A. Andreanum*, *A. Scherzerianum*, and the many hybrids, are all worthy of extended culture, but as the brilliant *A. Scherzerianum* is perhaps the most popular, the succeeding remarks may be taken as applying more particularly to this section. Broadly speaking, this plant occupies a position in our stoves in summer similar to that of the *Poinsettia* in the winter. They, too, are like the last-named in another respect, for though really stove plants, they are exceedingly useful for the embellishment of the conservatory. The plants are much less tender than was at one time supposed, and although considerable heat is required to bring them to perfection, they are quite safe in the conservatory during the flowering season, while a high temperature is not essential during the resting period. I look for the time when a collection of Flamingo Flowers, as *Anthuriums* have been called, on account of their gorgeous colour, will be found in every garden where gay flowering plants are required. *Anthuriums* should not be grown merely to represent the species or simply to add to the collection, but, where conveniences permit, should be cultivated by the dozen, according to the demand for decorative plants during the spring and summer months. For associating with Ferns nothing can be more effective for room and corridor decoration, and they will not suffer nearly so much under these circumstances as do many stove plants.

The cultural details are very simple. At the outset it must be borne in mind that the plant is an epiphyte, being found growing on the trunks of fallen trees where Mosses and other Cryptogams vegetate, and care must therefore be taken not to pot the plant too low or in too close a compost, as has sometimes been done in the past. The fact of its growing on trees in its native habitat suggests the methods of procedure for its successful cultivation in this country. A suitable compost is lumpy peat, sphagnum, leaf mould, charcoal, and sand, to be mixed to form an open fluffy mass. For small plants pots must be used; but they should be more than half filled with drainage, to be covered with a layer of moss, and the plant be potted high above the rim, after the manner of Orchids. For large plants pans are preferable to pots. About four to six weeks after potting, when the roots are showing through the surface, cover with green flake moss, into which they will penetrate freely. The plants should have a high temperature at starting, and be frequently syringed in preference to watering.

Anthuriums generally grow slowly at first, but when once established they are rapid in their movements, especially when assisted with liquid manure. That made from horse droppings has been found to assist the plants materially; cow or other cooling manures are, no doubt, equally useful, but guano is not recommended. An average temperature of 65° is suitable, but they are capable of enduring a much lower temperature, and will also flourish in a higher one. They have been seen luxuriating at 80° to 90°, and looking quite happy in 50° to 60°, and have further been known to be wintered in a house that was commonly down to 45°. There is, however, abundant evidence to suppose that this plant is not delicate and tender, and that it may be grown in any garden which has convenience to ripen Muscat of Alexandria Grapes. The rich scarlet spathes of *Anthurium Scherzerianum* render a healthy specimen a magnificent object, and it is a blaze of beauty over a long period. In young plants the spathes are rather small, but they increase in size as the plants gain in strength.—J.

Amaryllises at Chelsea.

WITH many people perhaps it will be a matter for speculation as to when the old name will go to the wall and the newer one of *Hippeastrum* be brought to the fore. That the latter is the more correct no one, it may be assumed, cares to dispute; but when a very beautiful class of plants has become familiar to growers by one name, it is no easy matter to oust it for a fresh one that is even longer and more unwieldy. One might say with the Bard of Avon, "What's in a name?" particularly when reference is made to such splendid plants as these. They are not plants that are found in every nursery or every garden, but in the latter, at any rate, they ought invariably to be grown, as they provide such boldly handsome flowers as cannot be seen in any other family. No better illustration of their effectiveness could be found, or need be desired, than is provided by Messrs. J. Veitch & Sons, Ltd., at the Royal Exotic Nursery, Chelsea. The *Amaryllis* or *Hippeastrum* exhibition there has become an annual event, and one which behoves every horticulturist who can find the time and opportunity to see.

The large span-roofed house that affords them accommodation is generally a magnificent sight by the middle of March, but this year the plants were fully three weeks later in attaining to perfection. Day after day the buds remained in one condition, and some of them continued thus over such a long period that they could never reach the highest state of excellence. There were, however, at the time of my visit hundreds of spikes carrying flowers of splendid substance, form, and colour. Rarely, indeed, have the plants presented a better appearance than this year. One observes, too, in addition to the greater range of colouration that the skill of Mr. John Heal has brought into the flowers that the foliage now comes with the spikes to some considerable extent, whereas only a few years ago the leaves were decidedly later. This combination materially enhances the general effect, as the leafage is very handsome in itself; the green colour is rich and acts as a most desirable foil to the gay flowers.

As with other florist's flowers hybridisation at the outset and subsequently cross-fertilisation has transformed the plants from a comparatively uninteresting, because restricted in colour, family to one of the greatest value from a decorative point of view. We now see as we take an elevated position at one end of the structure peculiar colours and shades that were unknown and possibly undreamed of only a few short years ago. These most desirable additions are the result of unremitting care and patience on the part of Mr. Heal, and there is probably no firm that can claim to have done one tithe as much as Messrs. Veitch & Sons in the development of the *Amaryllis*. Each year brings something new, and though the long sought for yellow variety is not yet an accomplished fact, one may see faint traces of its presence in at least two varieties; it is one of those colours that may or may not be secured, but one thing is quite certain, which is that if it never comes it will not be for the want of trying.

Amidst such a plethora of excellent varieties it is no easy matter to select a dozen or so and say that they are the choicest of the choice. One has to take at least four points into consideration in appraising the merits of an *Amaryllis*, and these are—1, colour; 2, form; 3, substance, and 4, size. To some persons, perhaps, the last named attribute would carry a considerable weight, but one must always bear in mind that a small flower may comprise the other three essentials, and that the chances are that increased age and strength in the bulb will bring commensurate increase in the magnitude of the flower. In some, however, such as Jas. H. Veitch, we find the combination of every excellent point, and have a perfect flower. The colour towards the outer extremities of the segments is very intense velvety crimson, deepening in the throat to a rich blackish crimson without the slightest suspicion of the green tint of which traces are found in many of the flowers. It is regarded at Chelsea as one of the finest dark varieties that has ever been raised. It is a noble flower in all its parts. In striking contrast to the last named is *Sostrata*, which is brilliant orange-red in colour, and while it has not the size of Jas. H. Veitch, it is of fine form and stout texture. Another dark variety that commands attention is *Merula*, the peculiar shade of which is most difficult of description. In a single word perhaps the best colour to name it is magenta, but it would require an artist to give a correct portrayal in words.

Handsome as are the dark *Amaryllis*, no one could possibly fail to admire the chastely beautiful lighter flowers. One of these, named *Iphis*, is a pure white save for the flush of delicate green that pervades it. *Zephyr*, scarlet rose with white margins, is one of the most charming, while *Leo*, white with rose on the upper portion of the flower, is likely to take the popular fancy. Other light varieties of undoubted merit are *Cupid*, rose and white; *Lycius*, bright rose with a considerable amount of white; and *Titan*, white and crimson. Though rather a small flower, *Zehina*, a brilliant orange-scarlet, is very fine, as also is *Nazara*, dark crimson, but the flower of the latter is of considerable size. *Xantho*, a deep velvety red, is superb, and the same may be said of *Laverna*, which is deep crimson. As a scarlet *Theodora* will not be easily surpassed, as not only is the colour good, but also the form, substance, and size. Of fine shape is *Medores*, which is of a peculiar brownish red shade, and with it this brief list must be closed. Let those who would like to see them remember that "time flies fast," and that the day will soon be here when the Chelsea *Amaryllis* will have passed to their rest for another season.—F. W. H.

The Delights of Gardening.—Everyone who has once tasted the real delights of gardening returns to it with zest. Tranquilly pursued it gives, says a contemporary, a certain richness to life and thought, a wholesome basis for intellectual labour. It is a common bond between the wise and the ignorant, a pursuit wherein men of different station can interchange rôles, and mutually impart knowledge. Rivalry is of the friendliest. The cottager's Rose may surpass that of a duke, and the interest of one in his specimen be as keen as that shown for the flower of the other.

Bulbs in Hyde Park.—The displays of spring flowering bulbous plants in the London parks, which are so eagerly looked for by all visitors, are now rapidly advancing in beauty. In the many beds that flank the walk running parallel with Park Lane the bulbs are flowering handsomely, and will be a source of delight to thousands of visitors during the coming weeks. Both the spring and summer bedding in this park are invariably exceptionally handsome, and many designs may there be noted for subsequent use in private gardens. The bulbs in Victoria Park are decidedly backward.—F.

Garrya elliptica.—I was pleased to see the illustration (page 288) of this neglected shrub, and was much interested in the accompanying remarks. When looking round the gardens of a friend a short time back I observed a plant growing on an east wall, and was informed it produced catkins 8 or 9 inches long with great freedom every year. The plant is worth growing as a shrub in the open or trained on a wall, not only for the sake of variety, but also for its unique appearance. It thrives in a mixture of fibrous loam and burnt refuse, annually top-dressed with leaf soil. I have seen beautiful specimens that have been treated as indicated.—C.

Overdoing Gardening.—I went to stay at a very grand and beautiful place in the country, where the grounds are said to be laid out with consummate taste. For the first three or four days I was enchanted. It seemed so much better than Nature that I began to wish the earth had been laid out according to the latest principles of improvement. In three days time I was tired to death; a Thistle, a heap of dead bushes, anything that wore the appearance of accident and want of intention was quite a relief. I used to escape from the made ground and walk on the adjacent goose common, where the cart ruts, gravel pits, bumps, coarse, ungentleman-like grass, and all the varieties produced by neglect were a thousand times more gratifying.—SYDNEY SMITH.

What Plants Require in Feeding.—There is yet a great deal to be learned regarding the positive influence of feeding various crops; yes, and even the different varieties of one plant respond differently to the application of fertilisers and water. These and similar questions afford good opportunities for investigation by experiment stations. At a meeting of the New Jersey Horticultural Society one of the most instructive papers presented was that detailing the work along these lines now in progress at the State Experiment Station. The excellent results that have been produced by the use of yard manure do but confirm the practical experience of so many. But the end is not yet, and the work merits the attention of growers everywhere. A further line of inquiry, and one not yet sufficiently advanced to be reported on is in connection with the tree fruits, from which we anticipate some important data. This is a study of the annual drain upon the soil for the essential elements of plant food. This was begun in 1896, when the trees were set; at the end of the season one tree of the several kinds of fruits was defoliated. The amount was recorded and a sample analysed at the station laboratory. The annual growth of these trees also is measured and recorded, and when trimmed, the amount removed is measured and samples taken for analysis. As the trees come into fruiting the fruit will also be sampled and analysed. This will be continued annually for a time, and "American Gardening" believes that at the end of a few years there will be in all probability very important facts regarding the growth of trees, and their annual needs as they develop and come into bearing.

Sugar Beet.—We learn that under the auspices of the Sugar Beet Committee of the Central Chamber of Agriculture, a limited number of experiments are to be made during the coming season in the growth of this useful vegetable. Oxford, Kent, Hants, Hereford, Suffolk, Beds, Wilts, Berks, Worcester, Lancaster, and Warwick have been selected as the counties in which the trials are to be made, and it has been decided that each plot selected for the experiment shall be at least 1 acre in extent.

Almond Trees.—The chief arboricultural attraction of the metropolis at the present moment is found in the hundreds of Almond trees whose branches are wreathed with flowers. The lateness of the season has of course affected them, as it has done everything, but though rather later than usual they are none the less appreciated. Thousands more might advantageously be planted in suburban London, where they appear to thrive in a most satisfactory manner. The Poplars in South London are rapidly swelling their buds under the influence of sunshine and shower.—H.

Where Market Gardening Pays.—The value of land under fruit, as compared with shooting preserves, was recently demonstrated, says a daily paper, at a sale at Yarmouth. A market garden occupation at Ormesby, four miles from the town, fetched no less than £1400, representing £280 per acre, the highest price paid for a long time for agricultural land in Norfolk. This was the first lot of the sale. The last lot touched the other extreme. This was a 3½-acre plot at Winterton, a few miles distance, which only realised £25, or less than £8 per acre, though it affords plover, snipe, and rabbit shooting.

Azalea Duchess of Wellington.—At the last meeting of the Royal Horticultural Society I observed, among the several Azaleas exhibited, a variety named Duchess of Wellington. This I thought one of the most charming plants in the whole exhibition. It had not the brilliant beauty of other exhibits, but was rather of a chaster and more refined type. The plant was shown by Messrs. R. & G. Cuthbert of Southgate, who received an award of merit. A Duchess of Wellington belongs to the Ghent section, and has neat flowers of a pale blush colour and with brilliant rose on the upper portion. It is a variety that can scarcely fail to find a wide popularity.—VISITOR.

The Barr Daffodil Cup.—It was most unfortunate that this cup should have been offered for competition on the occasion of the Royal Horticultural Society's meeting on April 10th. The effects of the lateness of the season were demonstrated by the fact that there was only one competitor, whereas there ought to have been at least half a dozen. It is, of course, impossible for anyone to know when the arrangements are made what the weather will be prior to the date chosen, but it seems regrettable that some scheme cannot be formulated by which a fair competition can be secured. There is certainly no honour in winning a prize when there is no other exhibitor; the honour comes with numbers of competitors, and the higher the average quality the greater the amount of interest derivable from the class. Messrs. Barr & Sons offer a cup that is thoroughly well worth the winning, and the keener the struggle the better for all concerned.—DAFF.

Leather Jackets.—These are said to be the well-known daddy longlegs in a grub state, and are so called on account of the toughness of their skins. Like other enemies of the gardener, they are not common to everyone; indeed, while they may be very familiar in one garden they are absolutely unknown in another. Their presence, however, is very quickly felt, either under glass or in the garden, when young plants such as Melons or Cauliflowers are planted in soil infested with them, and it may be said remedies for exterminating them are not many. I have recently had some trouble among Melons planted in newly cut soil, some being eaten off just beneath the surface. A search among the injured plants revealed the enemy lurking beneath the soil close by. Recent experience shows that not until they arrive at an adult or full-grown stage do they seek or take food—tender Melon plants. A lump of turfy soil placed on the bed near each plant acts as a decoy or hiding place for them during the day, and a morning search being instituted will soon clear them out. I have not tried this simple trap for them in the garden, but I do not doubt that it would be equally effective. This little expedient which has done me such signal service might be found useful to others similarly troubled. I cannot say whether old turf stacks are likely to be free from these grubs, or if they are found only in that recently cut.—W. S.

Late Rooted Chrysanthemums.

CUTTINGS rooted in the spring are each year becoming more appreciated, and really for many purposes late-rooted cuttings give the best results. In grouping, for example, there is no comparison between the big three-stemmed plants and those having only one stem bearing a huge single blossom. The latter lend themselves to better arrangement; each specimen can be placed so as to exhibit its cultural merits. Those seen at such shows as the Aquarium are very fine in this respect, for not only are the blooms large, but the foliage is especially fine.

If group arrangements at shows are improved by this system of culture, so too could conservatories be at home. Another consideration is that less time is required in growing the plants and the trouble slight compared to that necessary to obtain big specimen plants. Some varieties are better adapted than others for the production of single-bloom plants, it being well to choose those of a sturdy habit of growth. And in respect to that handsome Japanese variety Mrs. H. Weeks, this mode is the one now generally followed, since its peculiarity of late bud production is more understood. From what we hear of the habit of the handsome new variety Florence Molyncux, a similar plan of culture is advised, and the earliest flower bud a plant shows is secured.

A good time, then, to root a quantity of cuttings is in early April in a cold frame. After being duly potted singly they are allowed to grow about 6 inches high, when the tips of the plants are pinched out, except in the two cases noted above. This heading back is to delay the time each plant shall produce a flower bud, the object being to select crown buds in each case. Potting in the final size takes place before the small ones are root-bound, and then growth goes on without a check. For single stems of course all except one shoot are removed. A stick is fixed in each pot, and the shoot trained as required. A 7-inch pot is large enough for the strongest growers, a smaller size being employed for the more weakly. In the matter of soil and manures the plants require equally generous treatment to those grown in the more ordinary way for large exhibition blooms. These single stemmed plants have other advantages. They require less tying to prevent damage from wind, and being dwarf are easily managed to trap insect pests.

For what may be termed ordinary decorative plants, late-rooted cuttings are advisable. Oftentimes we meet with Chrysanthemums rooted early, but neglected and stunted through want of repotting in early spring. Such plants as these are easily beaten by late-rooted ones, which grow freely, and keep the foliage on to the last in a healthy state. The single-flowered Chrysanthemums, too, lend themselves to late propagation. Neat miniature bushes were last year grown from cuttings rooted as late as May. These in 6-inch pots were admired on account of their usefulness for decoration.

Most varieties esteemed for the big blooms may be cultivated on the one-bloom-to-a-plant system; still those named below are especially suitable because of their dwarfness and ample foliage. The buds, too, appear at a time when they may be secured to produce a well-developed flower. Annie Prevost, white; Belle of Castlewood, blush pink; Chatsworth, white and rose; Dorothy Seward, crimson; Emily Towers, pink, tinted white; Ella Curtis, yellow; G. H. Kerslake, jun., white; Hon. F. W. D. Smith, crimson; James Bidencope, rosy red; J. R. Upton, yellow; Louise, blush; Lord Ludlow, bronzy yellow; Master H. Tucker, crimson; Matthew Hodgson, crimson; Mrs. Barkley, rose; Mrs. Coombes, light pink; Mrs. J. Lewis, white; Mrs. White Popham, pink and white; Madame Gustave Henry, white; Madame G. Bruant, white and rose; Mutual Friend, white; M. Chenon de Lèche, yellow, shaded red; M. Hoste, bluish white; Occana, yellow; Phœbus, yellow; Pride of Madford, amaranth; Robert Powell, bronze; R. Hooper Pearson, yellow; Surpasse Amiral, yellow.—SPECIALIST.

April Potting Chrysanthemums.

THE majority of Chrysanthemums are now growing freely in 2½ and 3-inch pots. In order to continue them in a healthy and vigorous condition it is essential that they have more root room, so that the fibres can freely extend and multiply, enabling the stems to strengthen and the leaves to enlarge, the plants at the same time increasing in height. This growth must, however, be made under cool and airy conditions after the first few days succeeding potting. In a collection of Chrysanthemums it will be found that all do not require repotting at the same time. The most forward will probably be the strong growers which were rooted early. These ought to be

attended to before roots begin to mass round the sides of the small pots in which the plants are growing. This does not imply that roots must not be allowed to multiply freely round the ball of soil, as they should, before moving them into larger pots. The weaker growers do not root so rapidly, hence they may not be ready for a shift at the same time, but all that are in a proper state may with advantage be attended to.

The most suitable size for the April potting are 5 and 6-inch. Let them be clean and dry, and drain moderately well, with one large crock at the bottom, and over that some smaller sized, covering the whole with a layer of the fibrous parts of the compost. The soil ought to be fairly rich, and may consist of three parts of fibrous loam, one part of dried and sweetened horse manure, one part of leaf soil, one part of coarse silver sand, and one part of charcoal and wood ashes. The whole should be thoroughly well mixed several times, and if dry be brought to a moist condition.

It is important also that the plants to be potted should have the ball of soil and roots quite moist, therefore the day prior to potting make a thorough examination of them, watering all that are, or are likely soon to be dry. In potting turn the plants out of small pots, and pick away all the drainage. This will loosen the lower roots. The roots on the side of the ball need not be touched, provided the plants are just in the proper condition for the shift. Loosen the soil on the surface of the ball. Place a little compost in the pot, making it firm, then introduce the plant, arranging it so that the surface of the ball will be half an inch below the rim of pot. Fill in soil, working it down with a potting stick until it is at least as firm as the old ball. Insert a neat stick to each plant, and place the pots in a frame on a hard bed of ashes.

For a few days the frame may be kept close, and during that time no water is needed, but light syringing is beneficial. Water, however, must be applied before the foliage droops. Air should be admitted gradually. When the plants are established, expose them fully on favourable occasions, so that the growths may become hardened to full outdoor treatment in a short time. Stood in a sheltered position they will progress sturdily. On bright days the watering must be carried out as necessary, the freest rooting plants requiring it frequently. Afford plenty of space, as the growth is benefited by a free circulation of air and unobstructed light.—E. D. S.

Flowering Climbers.

CLIMBING plants are not sufficiently utilised in gardens, which can never be complete without its complement of flowering climbers. They are rarely used except for wall decoration; while there are so many desirable kinds and varieties, which if taken up tall poles would have a very charming effect, or trained upon trellises they might be used to hide tool houses, sheds, or any outbuildings from other parts of the garden. In fact, all suitable places about the house and grounds may be thus adorned; even arches at intervals placed over walks might be covered with them, or they may be trained over arbours or garden seats, when the comfort of their shade can be enjoyed in summer, while we admire the grandeur of their floral display, and inhale some of their lavish odours.

Few prettier objects can be found than the beautiful Wistaria, with its pale blue pendulous blooms giving out a sweet fragrance. By training this in different aspects the flowering period can be greatly extended, as in one aspect it may be just coming into bloom when in another it is passing away. Not many hardy plants afford such combined beauty, luxuriance, and wealth of bloom as the various forms of Clematis. Of the several types the Jackmanni section is the commonest in gardens, and the most popular, flowering during summer and autumn in continuous masses on summer shoots. Notwithstanding, however, that the large flowering types are very beautiful, it is questionable in many cases if they are so useful as some of the smaller flowering wild species. *C. flammula* is so sweetly scented that we can well afford to dispense with gay colouring. If planted in any ordinary garden soil it will quickly clothe a verandah, or porch; or if planted at the foot of some tree where the leafage is not dense, it will clothe the naked trunk with a wealth of green foliage, and if allowed to ramble at will, what can be more effective than when the shoots hanging loosely and informally are densely covered with pretty, sweet-scented, white blossoms, which are produced from July to October?

Clematis montana with its beautiful white fragrant flowers which are borne in clusters from the axils of the leaves, is also one of the best hardy climbers. Where bright touches of colour are desirable

C. viticella rubra may be added. The blooms are not large, but they are produced with great freedom from about June to October. It is of very vigorous habit, and will grow in shady moist places, where it would be too cold or too wet for more delicate forms to do well. *C. aethusaefolia* is also desirable. The stems are delicately slender, and the plant attains to a height of 6 to 7 feet. The flowers are produced in great abundance, and are Campanula shaped, and of a yellowish cream colour. Their drooping habit has a very pleasing effect when the plant is in full bloom, which is during August and September. Some of the hybrids, such as *C. Countess of Onslow* (fig. 93) may be advantageously grown in the garden as well as in the conservatory.

While speaking of flowering climbers we must not lose sight of the

in any little spell of mild weather which may occur in the depth of winter. Of climbers which spring up from the roots annually, the best is *Tropaeolum speciosum*, which is grand when seen drooping over a bit of rockwork, or covering a shrub or tree. It does well on a warm wall where it can be allowed to ramble among ordinary wall climbers. The double *Convolvulus* (*Calystegia pubescens*) is not grown nearly so much as it might be, for it is an excellent climbing hardy plant, producing in summer and autumn large rose coloured blossoms. The Everlasting Pea is another valuable ornamental climbing plant, of which many varieties are in cultivation, but we consider the white variety *Lathyrus latifolius albus* a real gem, although it has been much neglected by gardeners; its pure white

FIG. 93.—CLEMATIS COUNTESS OF ONSLOW.

climbing Roses, which are the joy of many a garden. But at the same time we cannot find space in our present article to enumerate any of sorts which have come under our notice. We will pass on to that favourite of every old-fashioned garden, the common Honeysuckle, with its sweetly fragrant flowers. The Honeysuckles proper, or *Lonicera caprifolium*, prefer a rich, moist, but well-drained soil, while the Scarlet Trumpet (*L. sempervirens*) and *L. reticulata*, require a warmer, lighter soil, and more sheltered positions. The blue Passion Flower, and its white variety, Constance Elliot, flourish in well-drained light soils, but they require to be planted in a sunny situation, and cut back to the old wood when the leaves fall.

The common Jasmine is perhaps the best climber for a town garden, and does equally well in the country. The winter-flowering yellow Jasmine should find a place in every garden, flowering as it does

flowers, produced in a loose raceme, are simply lovely. The type *L. latifolius* is also very showy. *L. sylvestris* is similar, but the plant is smaller in all its parts. *L. grandiflora* is not so rampant in growth as *L. latifolius*, but the flowers are very large and showy, having the keel and wings dark purple, and the standard large and broad of a lighter shade.

No hard and fast rules can be laid down in the planting of climbers, for no two gardens are alike. But here we have an infinite variety of plants for the embellishment of the garden. If possible they should be placed where they can have sufficient room to develop their beauty. Judicious pruning to promote vigour, and the removal of old growth will be needed. Climbers are nearly always beautiful—beautiful from the very wealth of vegetation that too often is allowed to run in them.—T. G.

Rose Show Fixtures in 1900.

* Shows lasting two days. † Shows lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear in an early issue.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Tea Roses.

ANYONE who has noticed the natural mode of growth of Tea Roses will have observed that to thrive at all well they must throw up a continual succession of suckers, first weakly, then a little stronger, and afterwards, if encouraged, stronger still. This, then, is the key to the only right way of growing them, and to make sure that all the suckers shall be of the right sort it is necessary to have the plants on their own roots. I know no reason for growing them on Briars or Manettis. It cannot be to make them grow stronger, for it has the very opposite effect in the long run. It cannot be to enable them to withstand the winter, because if they are killed down to the ground, all is gone but the Briar; whereas Tea Roses on their natural roots down in the ground a foot or two would probably start again from the base in the spring. Nor is it because they are difficult to propagate, for they are as easy to root as Verbenas. If it is argued that it makes them more floriferous, then remember that, with the exception of one or two sorts not strictly Teas, where there is growth, flowers will follow as a matter of course, and the finest blooms do not come on the weakest growths.

One summer I inserted cuttings of the best varieties I then had, including some which are not yet surpassed—viz., *Devoniensis*, *alba rosea*, *Catherine Mermet*, and *Souvenir d'un Ami*. The cuttings were made of the firmest growth of the current year, and placed under hand-lights on the north side of a wall. They soon rooted and started growing without losing much of their old foliage; they were then potted into 4-inch pots, placed in a cold frame, kept rather close and shaded till they started, then gradually hardened, and soon after—probably in September—they were shifted into 8-inch pots and placed outside. They were protected a little during the winter, being in a cold house not by any means frost-proof, and during the next summer were repotted into 14 and 15-inch pots, using soil such as would grow fruit trees well in pots—viz., fresh rather heavy turfy loam, a sprinkling of half-inch boiled bones, a few pieces of charcoal, and a little decayed farmyard manure of good quality dried and rubbed through a sieve. The loam was rough, many of the pieces being half the size of a brick. The following spring I had flowers such as I never saw before, and the plants kept constantly throwing up suckers.

Mildew does not often come spontaneously on plants grown thus without a check, though it often attacks others weaker in nature. When such a case occurs I practise and advise no half measures, but

gather all expanding flowers, place some sulphur with water in a water pot, stir well about, and apply with a syringe in a fine spray to both sides of every leaf in the house whether affected or not, and the first time the sun shines on it every spore will be killed. This is much easier and a far more effectual plan than dusting. The sulphur can be syringed off in a day or two, leaving hardly a trace behind. I do not think sulphur does much good in dull weather either inside or out; it is not at all easy to kill mildew outside in the autumn, when the sun has little power.

Tobacco powder is very useful for dusting whenever there is a suspicion of fly. It is certain death to the fly with which it comes in contact, and if applied in the evening when the sun is not powerful it will not injure the foliage even if allowed to remain on next day. Dusted over cuttings closely confined in a hand-light or bell-glass it will kill every insect whether it touches them or not, but in this case the cuttings must be protected from sunshine.—R.

Planting Flower Beds.

A CORRESPONDENT desires guidance for planting flower beds, but gives no particulars of the surroundings, only that the three beds are situated about 50 yards from the main walk on a slope facing the walk. The pattern is a semicircle, 30 feet across and 15 feet wide, and as the beds are somewhat novel, we give a sketch (fig. 94) of two of the beds, the other being simply a duplicate of that on the left hand. To give a meaning to the beds we have assumed that they are on grass or lawn, A, backed by a shrubbery or clumps of shrubs and trees, B, and the two side ones a background of shrubs, C.

We have also supposed that it is intended to occupy the beds with summer bedding plants. Centre bed, D:—a, *Canna Queen Charlotte*; b, *Zonal Pelargonium Vesuvius*; c, *Calceolaria Golden Gem*, or *Pelargonium Crystal Palace Gem*; d, *Lobelia Bluestone* or *Emperor William*; and e, *Chlorophytum elatum variegatum*.—Or, a, *Begonia*, tuberous, white or yellow var.; b, *Heliotropium Miss Nightingale*; c, *Centaurea*

FIG. 94.—DESIGN FOR PLANTING FLOWER BEDS.

References.—A, lawn. B, clump of trees and shrubs. C, group of shrubs. D, central bed. E, one of side beds. Scale 1 inch = 24 feet.

candidissima, dotted on ground of *Viola Cliveden Purple*, or *Viola Pilrig Castle*, blue; d, *Antennaria tomentosa*; and e, *Alternanthera magnifica*.

Two end beds, E, but same design as D; a, *Canna*, *President Carnot*, bronze; b, *Pelargonium*, *Madame Crousse*; c, *Lobelia*, dwarf blue; d, *Koeniga maritima*; and e, *Begonia semperflorens nana rosea*. Or, a, *Pelargonium Henry Jacoby* or *Pentstemon*, red or crimson; b, *Pelargonium Princess Alexandra*, silver leaf; c, *Iresine Lindenii*; d, *Sedum glaucum*, or *Alternanthera paronychioides aurea*; and e, *Echeveria metallica*.

Beds all three alike, design E:—f, *Pelargonium Flambeau*, scarlet Ivy-leaved; g, *Lobelia* dwarf blue; h, *Koeniga maritima*; i, *Alternanthera amœna*. Or, f, *Pelargonium Vesuvius*; g, *Pelargonium Crystal Palace Gem*; h, *Lobelia* dwarf blue; i, *Alternanthera paronychioides aurea*. Or, f, *Begonia*, tuberous, crimson or scarlet; g, *Centaurea candidissima*; h, *Ageratum Swanley Blue*; and i, *Alternanthera magnifica*. Any of these would be effective on a bank especially in large beds, and the arrangement might be varied according to plants at command or taste, those given being suggestive.

The beds are rather large, and the intention may have been to have mixed flowering plants, but this was not stated. They would answer for such plants as *Pæonies*, *Liliums*, *Delphiniums*, various bulbs, herbaceous plants, dwarf flowering shrubs, and annuals—that is, mixed beds. They would, however, be most effective occupied by summer bedding, and in turn by spring bedding plants, these being more striking when viewed from a distance than mixed beds.

Culture of Lettuces.

ALTHOUGH the Lettuce is by no means a difficult plant to grow, the production of large solid heads of crisp leaves is not so general in gardens as it should be. This is to be accounted for in many ways the main cause being sowing the seeds too thickly, and the subsequent crowding of the plants before they are pricked out in nursery beds and finally transplanted in the positions in which they are to develop. It is an evil that no judicious after treatment will altogether remove, although good culture will do much towards securing fairly satisfactory results from plants so neglected.

Lettuces—other points being properly attended to—will succeed in any fairly good soil. Early and late planting should be made in a warm and somewhat dry situation, this being preferable to a cool moist one. But these conditions are highly favourable to the production of Lettuces of the best quality during the summer and early autumn months. Liberal dressings of well decayed manure should be dug into the ground a good spit deep some time before setting the plants in it, although very satisfactory crops are yearly obtained by planting the ground the same day as dug. However, should the manure dug into the ground be of a rank description, it is certainly prudent to defer planting for a few days until the rankness has escaped.

If transplanting is not carried out in due time the plants become crowded in the seed and nursery beds, and poor results are obtained in consequence. Therefore, if the object be to produce examples of good cultivation in the shape of close heads of tender Lettuces, the young plants when a couple of inches high, and before they touch each other, should be pricked out on a border having a south or west aspect in rows about 4 inches apart and at the same distance in the rows, making the soil moderately firm about the roots, and if no rain falls at the time supply water through a rose watering pot to settle the soil about the roots. If the ground be ready by the time the young plants are fit for pricking out they may be placed in rows 12 inches asunder, and at the same distance between the plants in the rows, giving water to settle the soil about the roots, as already advised. Before planting the ground should be trodden and surface-dressed with soot, raking it level, as the Lettuces will do better by being planted in a fairly firm ground, and the dusting of soot will save them from the attacks of the grub, which in some soils is very destructive, eating through the stems of the plants underneath the surface of the soil.

However, very good Lettuces may and are very often grown on Celery ridges during the interval of making the trenches and earthing the Celery plants in the summer. But if plants thus grown are not well supplied with water at the roots during a spell of dry weather thin loose heads of tough leaves will be the result. Where there is abundance of ground the largest, most solid, and crisp heads of Lettuce are secured by sowing the seeds very thinly in drills about 1 inch deep and 12 inches apart, the ground having been previously dug, trodden, and raked level, afterwards closing the soil in drills with the feet, treading and raking it level in the same direction as the drills. In due time the plants should be thinned, first to 6 inches apart, and later to 12 inches in the rows. Thus grown, and being afterwards attended to in the way of giving water at the roots when necessary, the plants never experience the slightest check.

In transplanting Lettuces, which had been previously pricked out as indicated above, they should be lifted and planted with a garden trowel with good balls of soil adhering to their roots, letting them into the ground the same depth as they were before, and making the soil firm about the roots. In making early plantings of Lettuces level the soil well up about the stems of the plants so as to prevent the lodgment of water. But, on the other hand, in making plantations during the summer a slight depression should be left round the collars of the individual plants for the reception of water. Successional plantings, like the sowings, should be made every three or four weeks in the middle of August. The plants raised from seeds sown during the latter month should in due time be dibbled out, those in slightly heated pits at 6 inches every way from plant to plant, drawing every other plant for early use before they touch, allowing 3 inches between the plants in cool pits and in warm and somewhat dry borders out of doors. The plants in cool pits and out of doors must be protected from frost by shutters and fern and similar material. Slugs being very troublesome to Lettuce plants so grown they should be sought and destroyed, subsequently occasionally laying a mixture of fresh soot and lime between the plants and the wall, fence, or edging as a means of keeping them off.

Plants raised from seeds sown in June and July will be ready for cutting in the late autumn and early winter months. The July raised plants will be ready for lifting with good balls of earth, transplanting 3 or 4 inches asunder in a cool frame, placed on a south border, before they are injured by frost, say the end of October. The plants may be placed the same depth in the ground as they were before, giving water to settle the soil about the roots. This should be poured round the stems and roots, so as not to wet the leaves. These plants must have abundance of air in the absence of frost and heavy rains, and always bear in mind that the great enemy to be guarded against in the preservation of Lettuces during the winter is damp.

The only attention required in the several plantations made during

the spring and summer months from the interval of planting to cutting is to keep the plants well supplied with water at the roots during dry weather until they have taken well to the soil, and to keep them free from weeds by passing the Dutch hoe between the rows a few times, an operation that will at the same time promote growth in the plants.

In blanching the heads the object of the cultivator should be to get as great a portion of the leaves of the individual heads of Lettuce as white and tender as possible, therefore recourse should be had to tying up the leaves, but not too tightly, with bands of matting when the heads are nearly full grown. One band of matting tied within a couple of inches of the top of the heads is quite sufficient for each Lettuce.—S.

Royal Horticultural Society.

Scientific Committee, April 10th.

Present: Dr. M. T. Masters (in the chair); Dr. Müller; Rev. W. Wilks, Mr. E. Im Thurn, Mr. Hudson, and Rev. G. Henslow, hon. sec.

Vine Leaves diseased.—With reference to the samples brought to a previous meeting from Gunnersbury, Dr. Masters observed, from further examination, that they were certainly not attacked by red spider, but possibly by mites. There was still some doubt as to the presence of the young condition of *Gloeosporium*.

Oranges striped.—With reference to the Orange brought to a previous meeting, Dr. Bonavia writes further in regard to the criticism on his theory that the stripe did not correspond to a single carpel, but covered halves of two:—"If this be so, I think that fact would seem rather to strengthen my theory, for the law of phyllotaxis [alternation of whorls] would appear to require such a disposition. My view is that the peel and the pulp with carpels are two independent whorls, the former coalescing to form a protective covering, while the latter has its carpels separable." The difficulty in accepting this theory arises from the fact that there is no mark of separation, the spongy tissue being continuous from the ovary cells to the circumference, the latter being charged with oil glands. Secondly, if the superficial layer were "foliar" one would look for fibro-vascular cords running through it, whereas there are none. All that are present permeate the soft tissue. Lastly, if it were foliar it must represent a whorl of stamens; but where such a whorl takes on a pistillate character, they form short horn-like processes around the base only, and not a uniform covering.

Mandarine Oranges striped.—Mr. Hudson brought some fruit which always has slightly raised ridges, on a line with the backs of some of the carpels, and green. They proved to be quite superficial, only retaining the chlorophyll grains, which had disappeared elsewhere.

Acorn with three embryos.—Mr. Saville of Maplestead, Essex, on growing an acorn in water, found that it sent up three stems. They proved to arise from three distinct embryos within the common husk. Such polyembryonic conditions occasionally, but not very frequently, occur.

Douglas Fir diseased.—Dr. Smith reports on the specimen sent to him that it is attacked by *Phoma pithya*, but will add fuller details hereafter.

Potatoes diseased with scab, &c.—Dr. Smith also reports on samples received from Mr. Escombe, Penshurst, Tunbridge, in August, 1899. Prolonged cultivation of the fungi showed several species, that it was difficult to detect, which was the primary cause of the disease. "The skin of the Potatoes bore two distinct forms of disease. (1) scab, the cause of which is not yet known; (2) dark brown bodies adhering to the skin, called *Rhizoctonia solani*, being a mycelium of some unknown fungus. Other fungi present appeared to be Potato dry rot (*Fusarium solani*) and the Potato mildew (*Phytophthora infestans*)." Dr. Smith proposes to continue the culture, and to add a further report hereafter. Mr. Hudson observed that scab frequently appears on Potatoes when pig manure has been added to the ground. Such would appear favourable to the fungus which causes it.

Horticultural Shows.

Manchester, April 10th and 11th.

FEW people can realise the great progress which is being made by the Manchester and North of England Orchid Society. It was a happy idea to hold the meeting in connection with the Royal Manchester Botanical Society. In none of the classes was money awarded, but gold and silver medals of the Botanical Society and silver medals of the Orchid Society were granted to noteworthy flowers.

Messrs. Dicksons, Ltd., Chester, staged a fine assortment of miscellaneous foliage and flowering plants, receiving an award of merit. Mr. A. J. Keeling exhibited a choice collection, being honoured with a vote of thanks and certificates for *Cypripedium selligerum majus* Drewett's variety and *Laelia Jougheana* Keelingiae. Messrs. F. Sander

and Co., St. Albans, had a handsome stand. *Odontoglossum elegans* St. Albans var. received a first-class certificate; the silver medal accompanied this. Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs, sent a wonderful collection of *Odontoglossums*. The background was composed of splendid plants of *Oncidium sarcodes*. A silver-gilt medal was awarded by the North of England Orchid Society for *Odontoglossum crispum* The Earl, and first-class certificates for *O. excellens luteum*, *O. crispum* Victoria Regina, and *O. Andersonianum album maculosum*. Not only was the gold medal of the society awarded, but the Orchid Society awarded their silver medal. A gold medal, also the Orchid Society's silver medal, were accorded to Jno. Leeman, Esq., West Bank House, Heaton Mersey. The silver medal was unanimously awarded for *Dendrobium Venus*. Awards of merit were also granted for many beautiful and rare types.

† Messrs. R. P. Ker & Sons of Aigburth had a collection of *Amaryllis* and received the gold medal. Mr. John Robson's silver medal for a collection of Orchids was well deserved. Mr. James Cypher of Cheltenham was in fine form. Not only was the exhibit extensive, but every plant was of notable quality. Awards of merit were unanimously granted for *Sophranitis grandiflora giganteum* and *Dendrobium rubens magnifica*. Messrs. Charlesworth & Co. were remarkably good, especially noticeable being *Odontoglossum crispum* Duke of Connaught. An award of merit was adjudged for *Cattleya Schröderæ* Prince Patrick. The gold medal of the Society was deservedly awarded, and a silver one by the Orchid Society. A charming exhibit, brought from Worsley Hall by Mr. Upjohn, gardener to the Earl of Ellesmere, was much admired. A bank of seedling *Clivias*, handsomely grown, came from O. H. Wrigley, Esq., winning the silver medal in a most decisive manner. — Duckworth, Esq., had a splendid collection of cut Orchids. Charming, too, was the somewhat extensive collection of spring flowers sent by Joseph Broome, Esq., Llandudno. The Edwardian ware, much of which contained cut flowers and plants, formed a very pleasing feature at the entrance of the show.

Dublin, April 11th.

ROYAL visitors, wretched weather, and a fine display of flowers that bloom in the spring characterised this exhibition of the Royal Horticultural Society of Ireland. Mr. Hillyard, the courteous secretary, supported by a strong executive, augmented for this special occasion, planned all admirably, save the weather; and one could not but feel thankful that in spite of the flag-fever now raging in Dublin which, with the exception of some tastefully disposed trophies, they had contented themselves with gracefully entwining the bulky pillars in the entrance hall of the Royal University with a soft drapery of red, white, and blue. Severely simple as the decoration was, it was highly effective; and, moreover, the exhibits being practically confined to the spacious rooms on each side of the hall, ample space was afforded for suitably receiving the distinguished visitors, the Duke and Duchess of Connaught, the Princess Christian, and the Viceregal party, who honoured the show by a visit.

A fine floral circular shield, furnished by the Messrs. Henderson of Oakley Park Nurseries, which faced the visitors on entering, could not pass unnoticed, but space precludes more than a brief sketch of what was an excellent show. In the room on the right the Daffodil, in rare beauty and apparently endless variety, reigned supreme. Most conspicuous was a superb stand of ninety varieties, over which Miss Fanny Curry lingered with many a loving touch, and kindly pointed out the pet of her collection, Lismore, a chastely beautiful green tinted trumpet of her own raising. Here, too, with trumpets blowing all around it, was the Barian cup won by Miss Curry at the Drill Hall, London, on the previous day. Each variety in this stand was represented by about a score of fine blooms. In the same room the masses of yellow were relieved by 240 Rose blooms, staged by Messrs. A. Dickson and Sons of Newtownards, among which twenty-four faultless flowers of Catherine Mermet were very noticeable. Four boxes of these Roses were eventually commandeered by his Excellency the Lord Lieutenant for the delectation of our Queen, who from obvious reasons was unable to gratify loyal hearts and true by her presence at the show.

The special prize presented by Messrs. Hogg & Robertson, who put up a representative stand of blooms from their bulb farm at Rush, for a collection of *Narcissus*, was awarded to Lord Cloncurry, who also took the Drummond prize for a stand of twenty-four bunches in twelve varieties, and the society's prize for a stand of double *Narcissus*. In the popular class for twelve bunches, distinct varieties, competition was very keen. C. S. Spear, Esq., taking premier honours, being closely followed by Mr. Carroll of Dornden, whose superb blooms of *maximus* were very telling. To Dornden, too, went first honours for six pots of Tulips, exhibits of spring Cabbage, Broccoli, Lettuce, and a tray of six kinds of vegetables, the latter winning the bronze medal offered by Messrs. Tongood of Southampton. The same firm's silver medal for ten kinds of vegetables going to Lord Ashtown for a tray of high merit. Hyacinths were in good form, George Drimmie, Esq., Lord Ashtown, and Miss Martin leading in different classes, the best Tulips being staged by Lord Cloncurry; Edmund D'Olier, Esq., leading in class thirty-five for Roses. Strawberries were remarkable for size and colour, Lady Caledon, Lady Bury, and the Hon. C. F. Crichton setting up fine dishes of Royal Sovereign, and taking prizes in order named.

In the large concert room devoted to plants Mrs. Goodbody's table of *Amaryllis* formed a dazzling bit of colour. Nine good pot

Roses, staged by Mr. Crawford, well merited the challenge cup. Huge pots of Arum Lillies were splendidly shown by Mr. Coghlan, gardener to the Rt. Hon. I. M. Meade, and *Deutzias*, *Spiræas*, and other spring flowers were largely in evidence, although *Azaleas*, except some bright specimens of *mollis* from John Miller, Esq., staged in quantity were poorly flowered. Messrs. Drummond, Ltd., and Messrs. Henderson & Sons contributed to the general embellishment of the Royal University with plant groups; the Glasnevin selection of exotics proving, as it always does, very attractive; F. W. Moore, Esq., ably assisting, as usual, the Royal Horticultural Society of Ireland, which, unfortunately, does not receive that support from the general public it so well deserves. Perhaps the society is a little too conservative; perhaps not. However that may be, all connected with this spring show was admirably carried out, even to a substantial luncheon for the judges, for which thanks are returned by—ONE OF THEM.

Fruit Forcing.

Vines.—*Early Forced House.*—Red spider is the great enemy of Vines subjected to forcing, and is best kept in check by a timely sponging of the leaves. Syringing, even between the bunches, with the clearest water, militates against the appearance of the Grapes, and employing sulphur on the hot-water pipes is sometimes attended with serious discolouration in white Grapes. Inside borders, if needing a supply of water, should be attended to early in the day, so that surplus moisture may pass off before closing time. A light mulching of dry material will prevent moisture rising prejudicial to the Grapes, and may mitigate the tendency to cracking in certain varieties. Early Grapes do not always colour well, the defect chiefly arising from over-cropping, or continued hard forcing with attacks of red spider; it is only avoided by moderate cropping, rational treatment, and cleanly culture. A constant supply of rather dry, warm air, and a low night temperature will do much to assist heavily cropped Vines in colouring the Grapes.

Succession Houses.—The stopping and tying of the shoots must have attention. Where the space is restricted stop the shoots two joints beyond the fruit, and as foliage is necessary to sustain root activity as well as elaborate the juices, leave the laterals on the shoot both above and below the bunch, or at least those from the two lowermost eyes, and those level with and above the bunch. Pinch these at the first joint, especially those from the basal leaves, also those above, unless there is space for extending the laterals, when they may be allowed to make two or three leaves, but no more growth must be encouraged than can have full exposure to air and light. After the space is fairly furnished keep the growths closely pinched to one joint as made. The great evil in Grape growing is overcrowding, which deprives the foliage of light and air; and restricting the growth is intended to avoid that, and secure thoroughly solidified wood as it is made.

Tying Down.—It is a good plan to have the rods somewhat lower than the trellis, so that the side shoots have a slight incline upwards. In tying these in their places where they are to remain during the summer it is a common practice to begin to tie them down as soon as they are long enough to bend. This is not advisable unless as a precaution against injury from frost, as the shoots at this stage are so tender that the slightest twist the wrong way breaks them. It is a good method to defer tying down until the shoots are less sappy, which may be when the bunches are showing clear of the leaves. Sufficient space should be left in the ligatures for the swelling of the shoots. Stopping ought to commence when the leaf at the joint or place of pinching is the size of a halfpenny.

Vines in Flower.—Afford Muscats a free circulation of rather dry air and a temperature of 80° to 85° or 90° by day from sun heat, 70° to 75° artificially, and 70° at night, falling 5° on cold nights. Raise the points of the bunches to the light, and liberate the pollen at midday by gently rapping the footstalks of the bunches, or go over the bunches carefully with a large-sized camel's-hair brush, and afterwards dust them with another charged with Alicante pollen, or that of some different and free setting variety. Hamburgs set freely in a lower temperature, but they are better for a little assistance from fire heat, and other varieties are similarly aided during the flowering period.

Thinning Bunches and Berries.—It is advisable to make a selection of the best bunches, and leave only those required for the crop before they come into flower. This concentrates the forces on those retained, and by proper attention to fertilising the flowers a good set and finer bunches and berries are secured. Thinning the berries should commence as soon as they are set, especially in the case of the free-setting varieties, and where fine specimens are required for exhibition it should

be attended to while they are in flower. This concentrates the forces on those retained, and by proper attention they swell to a large size. With the shy setters thinning should be deferred until the properly fertilised berries can be distinguished by their taking the lead in swelling. Follow it up on dull days, or early and late in bright weather. Remove surplus bunches, under rather than overcropping the Vines, as too heavy cropping is fatal to colour and finish.

Feeding.—When the Vines are in full leaf, and the Grapes swelling, they require abundant supplies of nourishment. This may be given in liquid form, but it is not by any means the safest method, as an overdose sometimes destroys the young fibrous roots. Shankling also often follows filling the soil with organic matter held in suspension. All the advertised fertilisers are excellent and handy. It is best to give the borders a thorough supply of water, then supply the fertiliser, and water in moderately. By this procedure there is no fear of losing any virtue the fertiliser contains; but when it is given on a dry border, and followed by a heavy watering, it is likely to be worked into the drainage, and roots be encouraged at the bottom of the border instead of near the surface. A light mulching of short manure will be of advantage in keeping the border uniformly moist.

Late Houses.—The Vines are making rapid progress. Disbud and tie out the growths as they require it. Close the house early in the afternoon with sun heat, and maintain plenty of atmospheric moisture by frequently damping the houses and syringing the Vines at closing time, but not after the bunches show. Late Hamburgs are starting naturally, and need only a little fire heat to exclude frosts.

Young Vines.—It will be necessary to afford a gentle fire heat in cold weather to keep the Vines in steady progress, otherwise they are best allowed to start naturally, and secure a short-jointed growth by free ventilation. Disbud, leaving the best shoots on both sides of the canes and alternately at about 18 inches distance apart. The canes will have been depressed so as to cause them to break regularly down to the basal buds, when they can be tied in position. Crop lightly, one or two bunches being the maximum on permanent Vines. Any super-numeraries planted to fruit early, and afterwards be cut out, may carry a bunch on each shoot; six to eight bunches, however, are as many as vigorous Vines can bring to perfection, and fewer should be left on weakly canes.

The Kitchen Garden.

Dwarf French Beans.—The later sowings of these under glass succeed better in boxes than pots, not suffering so much from dryness at the roots. As heated pits are cleared of early Potatoes or other crops, they may well be planted with Dwarf Beans. Raise stock in 4-inch pots, and plant out of these in rows 15 inches or rather more apart. While the cold weather lasts, and till such times as the plants are well established in pits or frames, keep them somewhat close and warm, ventilating more freely when the cropping stage is reached.

Broccoli.—If midseason and late Broccolis are sown in quantity much before the end of April, the plants are liable to remain in the seed beds longer than is good for them. Sown now thinly in drills 5 inches apart, abundance of sturdy plants should be available by the time the ground is ready for their reception. Plants raised under glass, or thickly in a sheltered position, ought to be pricked out in nursery beds, disposing them 4 inches asunder each way. From these they should be eventually transplanted with the aid of a trowel—not drawn and replanted with a dibbler.

Cauliflowers.—For a very late crop sow seed of Autumn Giant as advised in the case of Broccoli. Plants of early and main crop varieties that were either raised last autumn or early this year in heat ought to be large enough and sufficiently hardened to plant out finally. Some of the earliest may well be planted at the foot of a south wall, and the rest either on a warm border or in hand-lights. All should be planted firmly in rich ground.

Lettuces.—Plants raised early and pricked into frames must not be kept in a crowded state. After hardening transplant to the open, moving each plant with a little ball of soil about the roots, and replant in rich ground. The Cabbage varieties may be arranged 8 inches apart in rows 10 inches apart, and the Cos varieties 2 inches more apart each way. Sow seeds if possible in drills where the bulk of the plants are to develop to their full size.

Onions.—Plants raised in pans and boxes have made poor progress, but, small as they are, all ought to be planted out before dry, hot weather sets in. Those that are somewhat drawn will recover most quickly from the check of transplanting if the tops are shortened somewhat. Plant in freely manured, well prepared ground, 6 inches apart, in rows 12 inches asunder. This work should be done carefully, burying the roots one-half inch below the surface, spreading them out evenly, and fixing firmly. Autumn sown Onions may also be transplanted, that is if this is not already done, treating them similarly to those raised under glass.

Tomatoes.—Plants that are being prepared for the open ought not to be left in the seed pans long enough to become drawn and weakened, nor should any early raised be kept in small pots from now to the end of May. The former may be placed singly in 4-inch pots, sinking them to the seed leaves. Return to moderately warm quarters till well rooted, when they may be moved into frames. Before earlier raised plants become badly root-bound, shift them into 5 inch or 6-inch pots, and treat as advised in the case of the later raised plants.

THE BEE-KEEPER.

Seasonable Notes.

ALTHOUGH the climatic conditions have been more favourable during the past fortnight, it has not been ideal bee weather, the wind remaining in a cold quarter. The few bright days experienced have made a great improvement in the condition of the stocks. The wind being in the south for forty-eight hours caused the temperature to rise. The bees took long flights, which have proved most beneficial to them. Bee-keepers have thus been able to form a pretty correct opinion as to the number of bees in the various colonies without disturbing the combs. Some of our stocks are strong, but others are indifferent. Owing to the late spring they are not as strong as usual at this season. We do not, however, think this will seriously affect them, as all vegetation is very backward, and the honey flow will probably be a fortnight later than usual.

Bee-keepers who have several colonies in straw skeps should study their requirements, and not allow them to become short of stores; the bees may be fed with thin syrup. If a piece of perforated zinc is placed over the hole on the top of the skep, a bottle feeder may be used, which will prevent an escape of heat from the brood nest. If there are no other bees kept in the immediate neighbourhood, open air feeding may be practised. A great quantity of syrup is not required at this season. The plan we adopt is to place a little in the feeders daily when the sun is shining, and it will then be carried into the hives. The disadvantage of open air feeding is the strongest stocks take the bulk, whereas in many instances it is the weak colonies which require the more food.

The past winter has proved the fact that straw skeps are to be recommended for wintering purposes. We invariably keep several stocks in skeps for early swarms. They are, however, useless to the modern bee-keeper unless the swarms are obtained as early as possible. The system we adopt most successfully is to place the swarms in frame hives, using full sheets of comb foundation; or, if we have them to spare, combs that were used the previous season for extracting. If this is done, it is surprising how rapidly the bees increase.

After Treatment of Swarms.

If a strong swarm is obtained before the end of May and treated as suggested, a hive containing ten frames will be filled with brood in less than three weeks, and if the weather is favourable during that time they will require little attention; but should it be dull and showery, which is often the case at that season, feeding must be resorted to. Only enough syrup should be given for daily consumption, as if the cells are clogged with syrup the queen will be unable to fill them with brood, which will cause a serious loss of workers when the honey flow comes. Natural swarms always work much more freely when treated in this manner, than if left to take their chance in an ordinary hive.

If several swarms are obtained and treated as above they may be worked on the same lines as the bees wintered in frame hives. If honey in sections is required a crate containing twenty-one sections may be placed in the hive as soon as it is crowded with bees. If extracted honey is preferred the stocks can be treated in the same manner as recommended in doubling hives. Shallow frames may be used. These are excellent for obtaining a good sample of honey, and the bees take readily to them. Combs that were used the previous year are to be preferred to comb foundation, as new ones are liable to break down whilst the honey is being extracted from them.

If full-sized combs are used it will be an advantage to take some combs from another stock to strengthen the one intended for honey production. These combs should be placed in the middle of the surplus chamber, and the empty combs on each side, as the greater the number of bees in a hive so will the honey be in proportion.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Planting Flower Beds (Gardener).—We thought it preferable, in view of the nearness of the bedding season, to give an illustration of your beds, together with explanatory notes, in the form of an article. If, therefore, you will turn to page 336, fig. 94, you will find an answer which will, we trust, be of assistance to you.

Seeds from Egyptian Mummy (H. M.).—The seeds are probably those of the so-called Egyptian Mummy Pea, as the three seeds are about the size of a Pea. We should sow them singly in 3-inch pots and place in a gentle heat, as that of a Cucumber frame or hotbed, and when up, if they germinate, keep near the glass, removing to a greenhouse when about an inch high, hardening and planting outdoors when the weather becomes mild. Perhaps, if you were to send the seeds to Kew they would be able to identify them for you. Some we have seen were simply grey Peas, and certainly had no connection with the mummy from the case of which they were taken.

Tips and Edges of Arum Leaves Turning Brown (Idem).—The usual cause is moisture deposited on them and hanging on the parts so as to destroy the tissues. This may result from syringing, or from keeping the house too close and moist, the atmosphere becoming what is known as stagnant. The preventive is to admit a little air and maintain a temperature of about 50°. Thus, with the air in motion, the water or air moisture is deposited on the glass or evaporates and passes off with the heated air, and the foliage, also spathes, develop properly.

Exterminating Rabbits and Rats (Conejo).—The best "cure" for the rats is poison, baiting the haunts for several days, and then use the vermin killer according to instructions. Smearing the holes with gas tar tends to drive the rats away. Another excellent mode of exterminating rats and rabbits is to pour some bisulphide of carbon into the holes and stop them up, but this is very inflammable, and requires the greatest care. Gas tar is distasteful to rabbits, and is best used on twigs or parts of branches placed at the entrance to the holes, so as to allow the rabbits free egress and ingress, yet so that their bodies brush against the gas tar. We have also used wire netting on the boundary, this being necessary where rabbits abound in the locality, having it let into the ground 6 inches and extending on the outside at a right angle a similar extent.

Vines Weak and Showing Small Bunches (H. S.).—Probably the Vines have been heavily cropped, and are showing the effects. This we suspect is the case, as "they showed good bunches last year," and although well manured with cow manure and lime every year the nutriment has probably been inadequate. We should give the Vines a dressing of the following mixture:—Bone superphosphate, dry and crumbling, three parts; sulphate of potash, two parts; and sulphate of magnesia, one part, mixed, applying 4 ozs. per square yard, and pointing into the border very lightly. It may be repeated when the Grapes have been thinned and are swelling freely. The extension system is the best for rather old Vines, or perhaps the semi-extension method, as they give finer bunches, the pruning not being so close as by the spur mode. The bringing up of young rods is an excellent plan, and mostly gives satisfactory crops. One Vine would be better than five, as there will be extension, and consequently more foliage relative to the crops.

Fruit-bearing Phoenix (J. C. S.).—Of the species comprised in the genus Phoenix, only three possess edible value. The Date Palm, *P. dactylifera*, produces the well-known dates; and the Wild Date, *P. sylvestris*, yields juice from which sugar is obtained, but it does not produce edible fruit. The Chitta-eita Palm, *P. farinifera*, affords from its trunk a farinaceous substance, used in times of scarcity, but regarded as much inferior to and less nutritious than common Sage. Of the other species *P. rupicola* is the handsomest, and next perhaps is *P. tenuis*, which in general appearance resembles *P. dactylifera*, but is slenderer and finer in all its parts.

Dip for Tomato Plants Infested with White Fly (F. S.).—We do not consider it would be feasible to kill any eggs there may be on the plants without injuring the foliage. The eggs are much more tenacious of life than the perfect insects, and the foliage of Tomatoes, from its hairy nature, is susceptible of injury. The insects are easiest destroyed by heating the hot-water pipes to 170° or more, and then painting them with a cream formed of flowers of sulphur and skim milk, keeping the pipes hot for about an hour, then allowing to fall to ordinary warmth, the house being closed. It is necessary to repeat this at intervals, so as to thoroughly destroy the pests as they emerge from the eggs.

Nycteria selaginoides (J. Row).—This plant is an annual that has been more or less largely grown in England for a number of years, and to some people the rose and white small flowers (fig. 95) have a never failing charm. It is very dwarf, and on this account is peculiarly useful for edging beds. The flowers at first glance resemble those of some of the *Silenes* and *Saponarias*, and like those of the plants named are profusely borne. *N. selaginoides* succeeds in any soil that is not heavy and wet, and must be treated in precisely the same manner as other hardy annuals. As you have several small beds that you fill with

FIG. 95.—NYCTERIA SELAGINOIDES.

annuals we should utilise the *Nycteria* for edging one or two of them, and if the seeds are good and the plants receive proper attention, we think you will be delighted with the result. Bear in mind, however, that, like other plants, it does not like to be crowded in dense masses.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (C. J. H.).—1, *Celsia arcturus*;

2, *Oxalis rosea*; 3, *Grevillea robusta*; 4, *Moraea sisyrinchium*. (M. F.).—1, *Dendrobium nobile*; 2, *Lycaste Skinneri*; 3, *Dendrobium Farmeri*; 4, *D. primulinum*; 5, *Cœlogyne ocellata*. (S. R. S.).—1, *Cyathea Smithi*; 2, *Dicksonia antarctica*; 3, *Asplenium bulbiferum*; 4, *Adiantum graeillimum*; 5, *A. cuneatum*. (A. G. L.).—Nareissi are florists' flowers that can only be named by comparison; send specimens to Messrs. Barr & Sons, Long Ditton, with stamped envelope for a reply, and we have no doubt they will assist you.

Dutch Farming.

IN May, 1899, a trip to Holland was organised by a number of Essex farmers, or rather, to speak more correctly, two trips, for the forty-six farmers were divided into two parties, and left England at an interval of a fortnight, though each party carried through the same programme. The report of the visit is before us, and we think some of its conclusions are worthy of note.

The places visited included various markets and farms, agricultural schools, an agricultural analysis station, a condensed milk factory, a co-operative cheese factory; coop, dairy, bulb, fruit and vegetable farms; and shrub nurseries.

The Dutch grow the ordinary English farm crops, but in addition there is a very large acreage of Rye grown for seed, Caraway, and Sugar Beet. The Rye probably finds its markets eastward in Germany and Russia, Dutch seed having been found profitable to sow, just as English farmers purchase warp-grown seed for the same reason. Caraway is used chiefly for kummel distillation, and is a very profitable crop; but there would be a very small demand for it in this country. Sugar Beet is said to be the sheet anchor of Dutch arable farming, realising as much as £60 per acre, but the value is artificially raised by the bounty put upon the export of sugar. This increases the price so much as to make sugar an article too costly for consumption by the Dutch working classes. If we consider the low price which the English workman pays for sugar, jam, and sweets for the children, we must conclude that the profit arising from this bounty system does not all return to the credit of the Dutch nation. The Dutch farmer not only gets the value of the sugar, but has the pulp for use amongst his cattle. It may fill a gap, but it must be poor stuff with all the juice extracted.

Dairying—the production of butter and cheese—appears to be the chief industry. One of the English visitors, Mr. E. C. Pritchard, says, "The English arable farmer will not find much to copy in Holland. Their methods of cleaning land and making ensilage are far from satisfactory, and their harvest operations would be too expensive, going back to the days of our great grandfathers; but when we come to the question of dairy farming the scene changes, and in dairying our Dutch friends are far and away ahead of us." In the parts of Holland visited all the cattle were of the pure Dutch breed. The Dutch cow is not a good beef animal, but as a milk producer is almost unrivalled. For instance, at the Waddinsveen dairy farm during the last six years the average annual production of milk per cow was 880 gallons, which is much higher than that of most English cows. The best cow gave 1179 gallons in 1897, and 1217 gallons in 1898.

Practically no heifer calves are fatted and killed in Holland; all are reared and tested as milkers, and only non-breeders and the few which fail as milkers are fed off in early life. In cleanliness Dutch farms, and especially the cowhouses, compare very favourably with their average British rivals. Listen to the report: "The cows are kept in a condition of scrupulous cleanliness, and to such an extent is the cleanliness of the cowhouses carried out in North Holland, where they form a portion of the farmhouses, that in the summer it is possible to use them as sitting-rooms." Again, "In view of the health and cleanliness of the Dutch herds, and of their great milk-producing value, the restrictions on the importation of Dutch, in common with all other live cattle, into this country appear entirely unnecessary."

This sounds all right, but it is difficult to draw a line between.

one country and another when they are in juxtaposition, and we know that some parts of Europe are very prone to, and in fact hotbeds of, cattle disease. In order to improve the breed of cattle the Dutch Government offers premiums for the best bull in each district, a condition of the award being that the animal shall thereafter be available at the request of any person living in the district, the customary charge for service being 1s. 8d. "In North Holland the bull travels from village to village." Private enterprise has been sufficient here hitherto to keep up and improve the breeds of cattle, and premium bulls will hardly be needed until the country is cut up into small holdings.

At the same time it is interesting to note the close interest the Dutch Government takes in the welfare of the rural communities and how it assists them in a way unknown in England. A peculiarity of the country is the nature of the farm buildings. "In North Holland the dwelling house, cow house, and cart or implement shed are all under one roof, the centre of the building where the high peaked roof gives the greatest height, being used for the storage of hay."

But how about sanitation? One of the party, Mr. T. S. Bell, says, "Here in this land of cleanliness are a farmer and his family living in one room under the same roof as twenty or thirty cows, and the only door of that room actually opening into the cowhouse. What would our district councillors and their sanitary inspector say to them?" The answer to this query lies in that one word cleanliness. How far removed from cleanliness is the average English cowhouse?

The Essex farmers found Holland a paradise in one respect; there is a plentiful supply of country labour; wages are 30 to 40 per cent. less than they are in Essex, and this cheaper labour must have much to do in enabling the Dutch farmer to pay his way. For one thing, it is no encouragement to parsimony in the matter of the labour bill, and this is seen to work out in practice, for "on the mixed farms visited it was found that the labour bill reached the high figure of £2 10s. per acre per annum, and it is thus evident that though individual wages may be low, the total amount paid for labour is high." Says Mr. B. F. May, "We often saw twenty labourers in one field, and I went into a field where thirty-four men, women, and children were on their knees hoeing Oats with short-handled spuds"

The whole party seem to have been much impressed by one noticeable fact; they saw no bad crops and no waste land. Mr. Pritchard says, "I do not think the whole of Holland contains 1 rood of derelict land." Even the hedgerows were hoed on some farms, and the grass by the sides of the fields was cut to the water's edge and made into ensilage.

Holland being so largely agricultural, the money spent by government in sugar bounties, premiums for stud animals, support of agricultural schools and analysis stations, and the construction of light railways, has to be provided to a large extent by the agricultural community, therefore taxation is as high there as it is here. The total taxation amounts to 10 per cent. of the income of the people, but farmers are not charged income tax, or tax upon capital such as other Dutch business men have to pay.

The English visitors were much impressed by the thrift of the people, and came to the conclusion that it was the chief factor in Dutch agricultural prosperity. By thrift is denoted the lower scale of living, and also the small amount of money spent in dress. To quote the words of one of the party, "A great deal of the prosperity of the Dutch may be accounted for by the old saying, 'He is not the richest who has the most money, but he who has the fewest wants in proportion to his means.'"

Work on the Home Farm.

The weather is still very cold, though there has been a fair amount of sunshine. Farm work has made good progress, in fact it has been the best week since Christmas. If hands were only more plentiful the arrears could soon be worked up.

A friend informs us that in his village the men lately struck work for a rise from 2s. 9d. to 3s. per day; the masters put up with incon-

venience, and stood firm, and after a few days the men returned to work, except a few wastrels, whose services were no longer required.

Barley is all drilled, and the latest has gone in dusty and well, but the land is cold for the time of year, and we do not expect a quick growth. The early sown has been a long time in the ground, and now it is up makes very slow progress, as if it were in doubt as to the season of the year.

Mangold must be sown at once. The wisdom of growing a fair acreage of this crop has never been so well demonstrated as in the past season. On strong soils Mangold is sometimes drilled on the flat, the land having been prepared previously, and the manure ploughed in during the winter; but we and most others prefer ridging. There is as good a chance of getting a plant if care is exercised, and we think we get heavier roots. The land should have been clean in early spring, and ploughed and rolled down in February. It will now be in a moist, fresh condition, and should ridge up well. The whole operation of sowing must be done quickly to avoid loss of moisture. The land must be ridged 28 inches wide, the manure be spread and shaken, the hand manure sown, the ridges split, and the seed drilled on the same day. The ridges must afterwards be lightly rolled down. Manure for Mangold should be short spit manure that has been turned, and is partly decomposed, having no straw amongst it. As manure on ordinary farm soil we should use 1½ cwt. sulphate of ammonia, 3 cwt. superphosphate, and 3 cwt. common salt, with a further dressing of sulphate after the plants are singled. Sow 6 lbs. per acre of good new seed. The seed should be put in water forty-eight hours before being required, remain in steep twenty-four hours, and then be spread out on a sheet in the granary to get the surface of the seed sufficiently dry for drilling. If not dry enough a little fine ash mixed with it will make the drilling go all right.

Ewes and lambs are very unsatisfactory; the ewes are poor, and are giving little milk owing to poor pasturage. All the lambs are below average in strength, and many weakly ones are dropping off. This will seriously reduce an already scanty crop.

THE PASSING OF THE AGRICULTURAL LABOURER.—Agriculturists in Lincolnshire—especially in the southern parts of the county—are suffering serious inconvenience owing to the difficulty in obtaining farm hands. In a measure this is due to the migration of the labourers to the towns, where they can command higher wages than in the rural districts, while the war is responsible for a further depletion. The difficulty in obtaining men has never, says the "Morning Post," been so great as that experienced during the present spring. In one village seven labourers' cottages were vacated at Lady Day, and all attempts to secure men in the place of those who have left have been unsuccessful. Agricultural work, consequently, is very backward.

PRACTICAL SHEEP HUSBANDRY.—Once a week fresh bright Oat straw will make a very acceptable change from the most nutritious of other kinds of food. Be sure to supply ample water to the flock. Let it be fresh drawn from a well, and see that the drinking troughs are not surrounded by ice. As the ewe is so will the lamb be. It is not enough to get the best ram possible and then neglect the ewe. Sheep love change; they fret when confined to one pasture or one kind of food. Do not stint the fodder or the grain. If there is any good reason for buying wool on the sheep's back for 18 and 20 cents a pound, is there any good reason why the grower himself should not hold it till shearing time? As there are many kinds of people so there are many kinds of sheep. We must not expect every ewe in the flock to bring as good and strong lambs—there are always weaklings and degenerate lambs in a flock—and it may be wise, says an American contemporary, to let these go, as weeds, to the waste pile before they have cost more than they will ever come to.

AUSTRALASIAN NOTES.—The increased value of wool has, from information from Australian sources, been most advantageous to the sheep owners in those colonies. At Wellington, New Zealand, in December last the special feature was the keen competition for the Kent, or Romney, wool, which is produced in large quantities in that district, one clip making as high as 11½d. in Wellington, New Zealand, with strange contrast to the value of this wool at home, whilst at the same market the Lincoln wool was also being strongly competed for, with a tendency of hardening prices. From Hamilton, N.Z., we learn that a further commission has been placed for the purchase of Lincoln rams for Argentina, the commission being restricted to shearing rams. This information shows that the competition between our home breeders and those in New Zealand for the supply of Lincoln rams to the Argentina market is not at an end. Consequently it is a matter that should have the serious consideration of our home breeders, whose interests are threatened by this competition, as to how this can best be met and overcome. Possibly the better plan is for the home breeders to avoid, as far as possible, shipping to the Argentine any other than first-class rams, which, when compared with their competitors from New Zealand, will, by their greater merit, larger size, and typical character, show that the English bred sheep are better than the Australian or New Zealand imports.—("Farmer and Stock-keeper.")

BARR'S GOLD MEDAL DAFFODILS

The Most Lovely
of all Spring Flowers.

The Finest Collection of

DAFFODILS

IN THE WORLD,
NOW IN BLOOM

AT

BARR'S NURSERIES,

A FEW MINUTES FROM SURBITON STATION (S.W.RLY.)

VISITORS INVITED.

Now is the time to select varieties while in bloom
for delivery in autumn.

A CONSTANT DISPLAY OF DAFFODILS IS ALSO
MAINTAINED DURING APRIL AT

12 & 13, KING STREET,
COVENT GARDEN, LONDON.

FRUIT TREES IN POTS.

FINE BUSHES OF

APPLES, PEARS, AND PLUMS.

Well set with bloom for the present year's fruiting, 42/- to
60/- per dozen. GRAPE VINES in pots, 2/6 to 10/6 each.
FIGS in pots, 2/6 to 7/6 each.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM
AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is ECKFORD'S
GIANT SWEET PEAS. The PURITY and
STAMINA of these Home Grown Stocks are
so conserved by SPECIAL METHODS of
CULTURE that the seeds are PHENOMENAL
for UNRIVALLED STRENGTH and VI-
TALITY, and with proper cultivation, give
the HIGHEST POSSIBLE MAXIMA of results!
Prizes offered in 1900 alone exceed £40!
Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA
NOVELTIES for 1900, sent gratis with each
Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively
UNRIVALLED by any on the Market for
FLAVOUR and CROPPING CAPACITY!
ENORMOUS YIELDS under favourable con-
ditions. Collections for 5 months continuous
supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that
ECKFORD'S SEED, for PURITY, VIGOUR, and
YIELD, are the CHEAPEST and BEST
ever offered to the Public! Collection for 12
months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all
carriage paid. Other Collections, 2/9, 5/-, 7/6,
post free.

A National Rose Day.

It be desirable that any flower
be worn on any particular day of
the year in commemoration of any
notable personage surely the royal
Rose should be that flower, and
the coronation day of Queen Victoria
the day of all others which should be thus
gracefully recognised.

The proposition of a Fellow of the
Royal Horticultural Society (on page 328, last
week) is an admirable one, and the reasons adduced
for carrying it out most cogent. The Rose by
common assent is the emblematical flower of
England, and there is no personage in ancient or
modern times with whose name it could be more
appropriately associated, on the anniversary of a
great historic event, than that of England's good
and venerable Queen Victoria.

Great as may have been the services rendered
to the nation in various ways and at critical times
in our long island's story by distinguished men
in peace and in war, there is no name that will be
more honoured through the coming centuries than
that of the revered monarch of these realms. Nor
will this be so simply because of the exalted
position occupied by her Majesty through a period
of time without a parallel, but because of the
manner of such occupation, and the resulting
advantages in the upbuilding of the greatest nation
of the earth and its ever growing prosperity.

How much our truly noble Queen has con-
tributed to this wonderful and mighty consummation
by untiring devotion to duty, by wise council, rare
experience, ripe judgment, purity of motive, and
grandeur of character—the grandeur of simplicity
that appeals to all—can never be fully described,
but it is not the less accepted because felt by
all classes of the community. There are none so
high who do not rejoice in doing reverence to the
occupant of the throne. None so low and needy
who do not feel they have a real friend there in
deep sympathy with them and with all who suffer
in the vicissitudes of life; and, therefore, all
delight in various ways to do honour to one who

has, during a long life, won their confidence, not more by her greatness in station than by her goodness of heart.

It is surely well to evoke the sentiment of a community and afford means within the reach of all for its symbolic display. Thus we find mutual pleasure incited and displayed by "favours" in celebrating domestic events; we have "colours" denoting loyalty to an "idea" or object as personified by an individual; we have the "flag that's braved a thousand years," of small material value, but as a symbol priceless, and which numbers of heroic men have defended by the cheerful sacrifice of their lives, while others are equally ready to do so. Both in war and in peace emblems have their uses in fostering unity and affording means for a common expression of feeling and admiration for a person or object believed to be good.

As all know, only quite recently the value of a symbol, initiated by the Queen, in promoting fraternal kinship has been remarkably demonstrated. As with the wand of a wizard, the "wearing of the green" has been invested with a significance very different from what it was formerly supposed to bear. From a badge of bigotry, as by some good people interpreted, it was suddenly ennobled as an expression of trust, loyalty, and good feeling between the Sovereign and peoples of the British Isles. That act of grace and tact of the Queen did more in an hour in engendering a spirit of good will among and between her subjects on both sides of the narrow sea than could have been effected by an Act of Parliament hotly debated for a session. The permission to wear the Shamrock of Ireland was intended and understood as an expression of trust in, and honour conferred on, her subjects. Let, then, these in turn honour the Queen by wearing the Rose of England on Coronation Day.

Just as one of these emblems was worn by men and women from all the sectional parts of the United Kingdom, so should, and would be, the other, in commemoration of an event as worthy of being celebrated as any that is to be found in the historical records of the nation. Let those who wish to honour St. George, whoever he was, by wearing Roses when they are scarce and dear, do so. Vendors will not complain, and the great multitude will look complacently on; but on the 28th of June Roses will be everywhere, and everybody will understand the wearing of them then and readily join in the celebration. It would be a great floral demonstration of the affection in which the Queen is held, and of rejoicing that her reign has been of such unexampled duration and beneficence.

It is interesting, as the proposer of the movement observes, to remember "that far back in English history the Wars of the Roses, red and white, showed how bitter racial animosity divided England; and now the wearing of Roses, of all colours, would show how the old divisions and hatreds had been healed in this mode of celebrating Queen Victoria's reign."

How, when, and in what manner the Rose became the emblematical flower of England, perhaps Mr. William Paul could tell us. His fine work, the "Rose Garden," contains much—very much—that is highly interesting historically, but the particular point, if treated, has been overlooked by the present writer. That it was the favourite flower of the luxurious Roman emperors is clear enough; and we are told that about 2000 years have rolled away since Sappho christened it the "Queen of Flowers." This was done in the following lines, written, of course, in Pagan times:—

Would Jove appoint some flower to reign
In matchless beauty o'er the plain,
The Rose (mankind will all agree),
The Rose the queen of flowers should be;
The pride of plants, the grace of bowers,
The blush of meads, the eye of flowers;
Its beauties charm the gods above;
Its fragrance is the breath of love.

Associated with Royalty through past ages, and now a favourite flower of the Queen, also, no doubt, broadly speaking the most popular flower of the inhabitants of the United Kingdom, it would be appropriate that it be selected as commemorative of the longest reign in the annals of history, and so abundant are Roses on Coronation

Day that they would be within the means of the millions to obtain. If as suggested a "national Rose day" should be fixed, then would the fragrance of the flower in city, town, and village be dispensed as the "breath of love" by the people for their Queen.

The Roses, moreover, would not be the production of foreign lands, as would be the case largely if an abnormally large demand occurred at a season when our home growers could only produce them under glass. Under these circumstances enormous importations from southern Europe would be inevitable; but in our natural Rose season the flowers required for a Royal celebration would be grown in the gardens of the British Isles. This, as perhaps will be generally conceded, would be entirely appropriate; it would further have a tendency to induce thousands of persons to grow their own flowers for such a purpose, and thus widen still more the deserved popularity of the "queenly Rose."

Another word. On the occasion of the completion of the sixty years' reign of her Majesty in 1897—the Diamond Jubilee—the Royal Horticultural Society provided a Victoria Medal of Honour in Horticulture for commemorating the event in perpetuity. This medal can only of necessity be held by sixty recipients. If the society can by the exercise of its great authority be the means of bringing about the celebration of Coronation Day in the simple floral manner suggested, instead of pleasing sixty people, it would afford gratification to millions. A strong recommendation widely distributed would have a good chance of success, and in any event the endeavour would be regarded as most creditable, not only by the Fellows of the Society, but by members innumerable of every class in the community, from peer to peasant, who would like to unite in a common method throughout the United Kingdom of doing honour to the Queen.
—V. M. H.

Salsafy and Scorzonera.

THE culture and treatment of these esculent rooted vegetables are practically the same. They are grown from seeds sown at the present time. In selecting a position for their cultivation choose one that is open and sunny, and where the soil has been deeply trenched with the special view of growing tap-rooted vegetables. In this case the manure used is placed very low down as a thick layer, and none at all in the soil above. Roots will then grow straight down, but if there is manure in the upper layers the result will be that the roots divide and are contorted in shape. On the other hand manure in the lower spit induces the formation of long straight roots of a good size.

Previous to sowing the seed break up a piece of ground to a moderate depth with a fork, so that it may be well pulverised and freed from rough stones, which would hinder the growth of the roots. Avoid forking so deeply that the manure at the bottom would be disturbed. Having made the soil fine on the surface, and of a good tilth, draw drills 15 inches apart and $\frac{1}{2}$ inch deep. Scatter the seed thinly along the drills or place three or four together at a distance of one foot, eventually thinning to one plant when the seedlings have grown a few inches. The cultivation consists in keeping down weeds, and stirring the surface soil to promote growth. Should the plants produce flower heads nip these out as soon as seen.

Salsafy is a hardy biennial with white skin and white internal tissue of the roots, which are tapering in shape and under good cultivation long. Scorzonera is a Carrot shaped root, but the outside skin is dark, while the internal tissue is white. This root is good but not superior to Salsafy, which is termed the "Vegetable Oyster." Both are fit for use in October, but after that month the majority of the roots should be lifted, growth being then completed and the roots as large as they will be the first season. Carefully lift without breaking them, and twist off the leaves from the crowns in preference to cutting them off, this latter method causing a certain amount of bleeding or loss of sap. When dry store the roots in layers of sand in a dry cool place, and withdraw as wanted for cooking.—E. D. S.

**Odontoglossum luteo-purpureum Mossi.**

There are now numerous varieties of the handsome *Odontoglossum luteo-purpureum* in cultivation, and Mr. de Barri Crawshay, Rosefield, Sevenoaks, has provided still another, and it has been named *O. l.-p. Mossi*. This is represented in the illustration (fig. 96), in which the strikingly handsome form of this variety can be readily seen. The sepals and petals are yellow, but this colour is almost wholly obscured at the base by brown, and the whole shines as if with a coat of varnish. The lip is very beautiful. The chastely fimbriated front portion is pure white with reddish brown at the base. The Orchid Committee of the Royal Horticultural Society at the meeting held in the Drill Hall on Tuesday, April 10th, recommended to *O. luteo-purpureum* an award of merit.

Cypripedium bellatulum album.

The typical *Cypripedium bellatulum*, that is so well known and so highly appreciated by Orchid growers, is fortunately abundant, and with reasonable care thrives well in most places. The white *C. bellatulum album* (fig. 97) is much choicer and rarer, and we are not surprised that a correspondent, signing himself "An Amateur Orchid Grower," has not met with it. Examples have nevertheless been exhibited occasionally at the meetings of the Royal Horticultural Society, where it was first shown by Mr. W. H. Young on June 11th, 1895. The flower is, as may be seen in the engraving, of perfect form, while the colour is pure white. On the occasion of its initial appearance at the Drill Hall it was accorded a first-class certificate by the unanimous vote of the Orchid Committee. It is described in the Journal of the Royal Horticultural Society as "a pure white unspotted form of great beauty."

Cypripedium bellatulum.

Excepting under very favourable circumstances I doubt whether this Orchid could be grown in a cool greenhouse. It is not so much a matter of temperature, as congenial atmospherical surroundings, which, for Orchids, can seldom be obtained in ordinary greenhouses. However, as this attractive species is not an expensive one to buy, an attempt, even if it resulted in failure, would not cost much. Established plants should, in this case, be suspended in a position where the

FIG. 96.—ODONTOGLOSSUM LUTEO-PURPUREUM MOSSI.

greatest amount of moisture is secured, and where the air is fresh and pure but not draughty. In a structure of this class shading would hardly be necessary. Water should be given by immersing the pots or pans to their rims in tepid rain water, so that all chance of any lodging in the axils of the leaves is removed. A simple way to tell whether

the plants require water or not is to gently bend a leaf, and if the action cause wrinkles more water is needed, but if stiff and rigid, sufficient moisture is present in the soil. Less harm will follow dryness at the root than prolonged saturation.—W. H. YOUNG.

Dendrobium Bullerianum.

This very pretty *Dendrobium* has never been common in collections, and is now seldom seen, yet it is one of the best of the showy flowered deciduous species, not unlike *D. Devonianum*, but rather stouter in growth. The flowers appear in the usual manner of its class along the last year's stems, and are about a couple of inches across, with rosy purple tips to the whitish sepals and a large yellow disc to the lip. It likes an ample moisture supply when growing, especially in the atmosphere, and may be kept quite dry while at rest in winter.

Mormodes luxatum.

I recently noted some very fine spikes of this Orchid, a plant that some may think more curious than beautiful. I consider it one of the best in the genus, but it is not often, I think, seen in flower so early. This may be accounted for by the fact that the plants have been kept in heat all the winter, not the wisest of proceedings according to my

FIG. 97.—CYPRIPEIDIUM BELLATULUM ALBUM.

experience of it. I have found it do well when wintered on the dry side in the Cattleya house, exposed as much as possible to the sun and allowed plenty of air.

In early spring more heat ought to be allowed, and the change should be rather quickly brought about, this being conducive to free flowering. The plants should remain in heat until the growth—and the spikes if any appear—are progressing freely, and finished with ample sunlight in a more airy if not a cooler house. Although the flowers last a little longer in a cool dry house, it is not wise to keep them out of their growing quarters too long, as the young heads are apt to be checked, and this may prevent their flowering the succeeding season. In colour the blossoms vary considerably, the type having yellowish flowers, slightly rose red, with reddish brown. The creamy white variety *eburneum* and the spotted *punctatum* are both charming forms.

Odontoglossum Mulus.

The origin of this species or variety has always been doubtful, many considering it a hybrid between *O. luteo-purpureum* and *O. gloriosum*. It has always struck me as having a little of *O. Halli* in it, but whatever its origin, it is a fine garden Orchid—free flowering and very handsome. I have known it to produce branching spikes with flowers larger than the majority of *O. luteo-purpureum*, and the blotches are in some cases clean cut and bold, like those of *O. Wilckeanum*. It is easily grown, thriving well in a cool house under the conditions usually allowed for *O. crispum*.—H. R. R.

Royal Horticultural Society.

Special General Meeting, April 25th.

THIS meeting was called with a view to the consideration and sanction, if approved, of new bye-laws, which were rendered necessary under the new charter of the society; to consider the desirability of removing the gardens of the society from Chiswick to some more suitable site as a means of celebrating the centenary of the society, which is now rapidly approaching; and to consider the desirability of the society collaborating with certain other bodies to establish on the new garden a school of horticulture. As is customary, the president, Sir Trevor Lawrence, Bart., occupied the chair, and he was supported at the table by Sir John T. D. Llewelyn, Bart., M.P., and Messrs. J. T. Bennett Poë, T. B. Haywood, C. E. Shea, Frank Lloyd, W. Marshall, P. Crowley, Jas. Hudson, and the Rev. W. Wilks. Amongst the Fellows present were Sir Wm. Thiselton Dyer, Sir Michael Foster, Dr. Maxwell T. Masters, and Messrs. G. Paul, G. Bunyard, G. Nicholson, H. J. Pearson, R. Wilson Ker, W. Watson, C. T. Drury, H. Balderson, J. Douglas, G. Gordon, G. Wythes, J. Wright, W. H. Divers, E. Beckett, H. Pinches, L. Castle, A. Dean, J. Weathers, C. J. Salter, J. Cheal, A. Mortimer, C. E. Pearson, H. S. Rivers, W. Roupe l, with many others.

It was originally intended that the meeting be held in the Lindley Library, but as the accommodation there is limited, it was resolved to go to the canteen of the London Scottish Drill Hall, and though this room was not packed there was a goodly attendance. The removal, of which no notice had previously been given, caused some delay, and several Fellows were late from this cause alone. There was apparent an air of suppressed expectation, and the participators in the meeting waited developments. It was generally surmised that the policy of the council would be severely criticised, and this proved to be the case, though practically nothing definite was decided at the meeting.

After the notice convening the meeting had been read by the secretary, the president brought forward the first recommendation of the council respecting the adoption of the bye-laws. These were, he said, rendered necessary by the new charter, and considerable time and care had been expended upon their formation by the society's legal advisers in endeavouring to bring them up to date, to make them thoroughly applicable to the society at the present day, and to reduce so far as possible the somewhat unwieldy length that had hitherto characterised them. Sir Trevor suggested in view of the fact that they had been available for consideration by the Fellows for several days that they should be taken as read, but this was met by almost general dissent on the part of those present. Sir Wm. Thiselton Dyer and Sir Michael Foster evidently voiced the views of the majority of the Fellows when they protested against the non-distribution of these bye-laws to the Fellows in order that they might be thoroughly considered and digested prior to the meeting. It was thought that a document of such moment was worthy to have been posted in a formal and official manner. Sir William concluded by moving that the consideration of the bye-laws be deferred to a subsequent meeting, so that Fellows might study them, and if necessary bring forward various alterations or amendments. Dr. Masters seconded this. Sir William also protested against the manner in which the notice convening the meeting had been distributed, and received the support of Surgeon-Major Hince, who however, considered the bye-laws excellent. Before putting Sir William Dyer's motion, Sir Trevor Lawrence pointed out that the council had no objection to an adjournment, but that the society's lawyers had pointed out that the new charter abrogated the old bye-laws, and that they were now a society without laws. Mr. A. Dean said he had sent a stamp for the bye-laws, and had received them, and supposed that other Fellows could have done the same, and that personal application had not been necessary. The proposal for adjournment was, however, carried by a large majority. The suggested bye-laws will be distributed to all the Fellows prior to next meeting.

This matter having been disposed of, Sir Trevor rose to refer to the second portion of the business of the meeting. This had reference to the most suitable means for celebrating the centenary of the society. He referred to the fact that at the annual meeting held in February he had spoken at some length of the scheme that should be adopted, and that he had then affirmed that the most popular means of celebration would be the provision of a central hall of horticulture. To this opinion he still adhered, but the difficulty of finances had to be faced. The Fellows were, no doubt, aware, continued the speaker, of the strenuous endeavours that were made some years back by Baron Schröder to establish such a hall, when the whole matter was seriously discussed, and it was estimated that a sum of at least £40,000 was absolutely essential, of which only £27,000 were forthcoming. Thus the scheme collapsed, and, so far as he could see, the prospects of to-day were no brighter. This not commending itself to the council as feasible, it was recommended that the garden be removed from Chiswick. In dealing with this the council

had considered the fact that the society had still twenty years as the residue of the lease, and that this must be regarded as a valuable asset. Personally, continued Sir Trevor, he had never considered Chiswick good enough for the society; it was too small, and lacked that variety of soil and aspect in which lies, to a large degree, the value of such a garden. Moreover, the garden was becoming more and more enclosed by villa residences and some factories, and the soil was yearly becoming poorer and poorer. The council had, bearing these and many other facts in mind, decided that the most suitable means of celebration was the establishment of a new garden, and in this view the members at the general meeting in February had acquiesced, and Sir Trevor did not think they would now go back on the assent then given. No ground was then specifically mentioned, as many sites were under inspection and discussion, and in conclusion the speaker moved that the meeting should confirm the recommendation of the council to remove the garden from Chiswick.

Mr. H. J. Elwes was the next speaker, and occupied the meeting at some considerable length. At the outset he stated that it was obviously impossible for the meeting to decide upon the abandonment of the old garden until a new one had been found. He was, he affirmed, reluctant to come into opposition to the council, but he considered it necessary in the best interests of the society. He laid great stress upon the importance of unanimity of the council in such an important matter, and pointed to the resignation of Mr. Arthur Sutton, as the latter gentleman could not agree to the council's recommendations. He stated that he had not received a notice of the meeting, but this must have been owing to an oversight, as each copy of the recently issued *Journal* had contained to the notice on red paper. He considered the several reasons, such as the soil and situation being unfavourable invalid, as there were several neighbouring gardens of great excellence. He would not, however, oppose removal if something better could be found. He made some references to financial matters, but Sir Trevor Lawrence pointed out that he was not apparently so well qualified to speak on these as on the gardening aspect of the case, as he was inaccurate in several essential points. Mr. J. Weathers supported Mr. Elwes' motion that the two schemes relative to the new garden and the acquisition of a site at Limpsfield be considered as one, but it was not put to the vote. Mr. G. Paul was emphatically of the opinion that Chiswick was exhausted.

Sir Trevor Lawrence then brought forward the motion that the garden should be removed from Chiswick, and this was seconded by Sir John Llewelyn, and it was eventually carried unanimously with an important addition from Mr. H. J. Pearson—"subject to the Council finding a new garden that was acceptable to the majority of the Fellows of the society." Mr. Roupell thought it would be better to retain the old garden, and was of the opinion that it sounded peculiar for such a society to lay itself out to teach the art of horticulture, at the same time as it acknowledged its inability to renovate its own ground. Mr. Roupell's assertion that the fogs of London were not so bad as they were in the past was received with some derision, and certainly is not in agreement with the majority of London horticulturists, who, as a rule, hold the view that they are decidedly worse.

Sir Michael Foster followed with some pertinent remarks regarding the immeasurably more popular notion that a hall should be the means of celebrating the centenary, and said he had yet to learn that much good could not be done with a smaller sum than £40,000; but Sir Trevor Lawrence dissented strongly from this view, for reasons that he had already set forth.

The chairman at this point considered it desirable to assure the meeting that the council had not gone into this matter with their eyes shut, but had done the very best that could be done. He referred to the fact that several sites had been carefully inspected by experts, but all had been rejected except Limpsfield, upon which the report was favourable, save that the land having been neglected it would require much labour and especially perfect drainage to bring it into proper working condition. The council, he said, welcomed the criticisms of the several gentlemen who had spoken, as there could be no doubt that they were given in the friendliest spirit, and because the speakers had the very best interests of the society at heart. He then suggested that the meeting be adjourned, and promised that proper notice of the date of the next meeting should be given.

Sir William Dyer said the meeting would be sorry to dissolve without acknowledging the conciliatory manner in which the council had received the various remarks, and considered the tone of the meeting augured well for the future of the society.

It was then asked if the council would receive recommendations from Fellows as to other sites, and an answer in the affirmative was given. Mr. Gordon wanted to know something about Limpsfield, but this question was relegated to the subsequent meeting, Sir Trevor Lawrence remarking that the society was not committed in any way.

On the proposition of Surgeon-Major Hince, seconded by Mr. Balderson, a hearty vote of thanks was accorded to Sir Trevor Lawrence for his services in the chair.

Basal Rot in Narcissi.

THE present moment, when many hundreds of thousands of Daffodils will be in bloom, cannot be other than opportune for putting forth the exhaustive paper by Mr. Wm. Crawford, M.D., Uddingston, N.B., which was read at the Royal Botanic Gardens. We extract this from the quarterly record of the Royal Botanic Society of London, and commend it to the particular notice of our readers as containing valuable information relative to the disease, and also embodying suggestions for its prevention.

Of all the difficulties surrounding the growing of Narcissi, either on a large scale for commercial purposes, or on a smaller scale for pleasure, none are so disappointing as that insidious decay which the Rev. Wolley Dod was the first to describe and call by the name of "basal rot." The whole question of successful culture is bound up in this term, and while an occasional bulb may go down through the ravages of the *Narcissus* grub, whole plots of certain varieties may be swept away in two seasons by decay.

As a boy I was struck with the impossibility of growing the wild "scoticus" of our glens in the cultivated flower border, and, in more recent years, when I began to form a collection, I was met by the same difficulty in very many varieties. My first collection, over ten years ago, was planted under the same cultural conditions with very unsatisfactory results, and I was at once convinced that the varieties of *Narcissus* springing from such varied conditions of cross-fertilisation and in-breeding required very dissimilar treatment, for while single and double poeticus Van Sion and many of the bicolors (planted in porous soils) revel in heavy mulchings of farmyard manure; the spurious class and white trumpet section sicken and die in two years in the same soil, under what would be styled for any other plant very careful treatment.

Nature's Rules.

Now Nature, though slow, is a sure and safe guide, and it will be well to turn for a moment to her and learn how she deals with the *Narcissus*. Our native Lent Lily, which has a wide distribution over the whole of the western counties of Scotland, is found in its greatest luxuriance in sloping woods and glens where the soil has been undisturbed by the hand of man. If this plant is put into cultivated soil it goes down immediately. Reasoning from these data we may arrive at the conditions necessary to healthy culture and the conditions leading to disease. In the uncultivated soil "scoticus" received the plant food which ministered to its perfect development; in the cultivated soil it met with something over which it sickened and died. It is our purpose to find out what that something is, and the correct rendering of it will be a solution of the "basal rot" question.

All plant food resolves itself into four elements: Nitrogen, phosphoric acid, potash, and lime; these four are essential to all perfect plant formation. Yet we find whole families of plants that have a special preference for one element more than another—the Grasses delighting in nitrogen, the Brassica family in phosphoric acid, the Leguminosæ in potash; and all successful manuring is comprehended in supplying the special wants of the plant. In the vegetable, as in the animal kingdom, what is one's food is another's poison, and this is particularly so of the *Narcissus*. The *Narcissus* is a phosphate and potash-loving plant; evidently the slightest quantity of free nitrogen or ammoniacal compounds is poisonous to it. In uncultivated soil, Nature has formed her plan, that there is no excess of nitrogenous compounds from decaying manure, and the potash and phosphatic elements have not been eaten out of it by continuous cropping; but the very reverse occurs in the cultivated border, where there is an excess of ammoniacal compounds with generally a deficiency of potash and phosphates. The balance of manurial ingredients is reversed, and the bulb falls a victim to those changes (caused by microbic action), which are going on in cultivated soils.

The Physical Signs of Basal Rot.

It is not necessary for me to detain you with a description of the outward or physical signs of "basal rot." There are just two to which I would draw particular attention, as the one is a guide to a choice of bulbs while buying, and the other the first indication that something is wrong with the stock. The first sign is that of the brown thumb-like markings on bulbs that are just affected; these markings may be very slight or run into a burnt and scrubby appearance of the whole outer tunic of the bulb. Avoid such bulbs however little they are marked, as they are already infested with the microbe "*Penicilium*." The second sign is the stunting and clubbing of the foliage, with the ends of the leaves withered. The vascular bundles of what we might call the inner or feathered side of the leaf atrophy, while the vascular bundles of the outer side continuing to grow, cause a clubbing of the leaf. This is a sure sign that the stock is affected. The foliage of such bulbs will die down a considerable time before the foliage of healthy bulbs. All such bulbs should be lifted whenever the foliage dies down, and be well dried during the summer.

The microscopic examination of the bulb demands our earnest attention, because, if my contention is correct, we shall find in it the

true secret of "basal rot." I have been fortunate in having the aid of an expert microscopist in determining in every instance that the microbe "*Penicilium*" was the active injurious agent in all bulbs affected with basal rot. I need not go further into the methods of examination than to say that seemingly healthy portions of diseased bulbs cultivated in Koch's jelly always revealed this organism.

I am quite sensible that I shall be met with the reminder that this "*Penicilium*" is nothing more than the mould or fungus which affects all vegetable substances in the processes of decay—that it is in no sense specific to the bulb as the Potato fungus is specific in causing the Potato disease. My answer is, that it is quite possible that this "*Penicilium*" is specific in the sense that it has more affinity for bulbous structures than it has for ordinary decaying vegetable products, and that when bulbs are planted in such soils they immediately begin to suffer. All cultivated soils are teeming with this microbe, especially near the surface, but the organisms become fewer deeper down, until a depth is reached beyond the ordinary cultivated area where they are absent. Wherever one has decaying manure or vegetable products giving rise to ammoniacal compounds, one has "*Penicilium*." In such soils bulbs, especially of the spurious class or white section—what we might call inbred bulbs with delicate constitutions—will fall a prey to this germ or fungus. I look upon the species of *Acarus* or mites, which some observers have described, as scavengers, eating up and clearing away the already all but dead bulbs.

If my reasoning is not correct, how otherwise is it that *Narcissus* "scoticus," one of the hardiest plants in its native habitat, fails immediately it is placed in cultivated soil? It is not that it is starved in the rich border—it is that it is poisoned with ammoniacal compounds and infested with the fungus "*Penicilium*."

Experiments in the Prevention of the Disease.

At first, as a safety, I tried various expedients to ward off the "*Penicilium*"—surrounding my bulbs with rough sand, soil from banks of rivers, and road grit—with partial success. Some have used burnt clay, which is simply soil sterilised and freed from the "*Penicilium*." I look upon all these as antiseptic screens. But sooner or later the *Penicilium* will pass through these, or perhaps, entering the bulbs through attacking the roots, will destroy them.

The conclusion I have come to is that with deep planting where "*Penicilium*" may be either few or absent; with antiseptic screens of various kinds and yearly lifting one may get on fairly well in cultivated soils; but to be really successful one must go back to Nature's plan, and use soils that have long lain undisturbed—that are free from decomposing vegetable or manurial ingredients, and consequently free from "*Penicilium*." In such soils, with a dressing of phosphatic slag-meal at planting and a dusting of potash over the beds about the end of January, ample success will follow. And to make surety doubly sure, sow the beds with fine lawn grass seed, and there will be little to fear. The grass, with its strong affinity for nitrogenous compounds, will speedily clear the ground of these, and leave nothing for the fungus "*penicilium*" to make a *nidus* of. This is the reason why Daffodils do so well in grass.

My own plan is to plant in an old grass field, turning the turf well down. After opening the trench, I gave a good dusting of slag-phosphate into the bottom of the trench. Next I put in a layer of marl. This is a pure carbonate of lime found extensively on the sea shore in the neighbourhood. Into this marl I plant my bulbs and give them more on the top, until, I may say, they are completely surrounded with an agent in which no germs can possibly be present. As anyone who has used potash in growing bush fruit, and knows its value, it is wise to dust the beds through the winter with a sprinkling of the sulphate of potash or with kainit, to give abundance of flowers of a fine colour and texture. For those who work on a smaller scale and cannot get old lea land to turn down, the proper plan is to sow down the bed with grass seed the first season and plant the bulbs in the grass the next. By this time the land will be becoming free of the nitrogenous compounds which give rise to and perpetuate the "*penicilium*;" in other words, the grass will have eaten them out for its own nourishment, and the land will be what is called mellow or sweet.

There is no doubt that the Dutch growers largely save their stocks by yearly lifting and drying; but they also complain that they have a great difficulty of growing many varieties in their highly cultivated soils, though they are wise enough to manure the previous crop before planting *Narcissus*. They take a crop of Potatoes or other produce off the ground, which removes the greater part of the ammoniacal compounds and leaves the soil freer of nitrogen. But even with this treatment, many Dutch stocks are affected when they arrive in this country; and sometimes one is apt to blame one's own soil when the disease was already present in the bulb at planting. I look on the Dutch system of growing as a rushing of the bulb through its active state of growth. By planting in the autumn, when the vital action of the bulb starts, and lifting in the early summer, when it ceases, the very vitality of the bulb wards off the disease. Were the Dutchmen to allow their bulbs to lie in their heavily manured ground all the summer through, the results, I fear, would be disastrous, for the "*Penicilium*" is much more active in warm than in cold weather. The serious losses that I had at first occurred during the summer, when the bulbs were allowed to lie for increase.

Deductions from Personal Observations.

These, then, are the conclusions I have come to—that the widespread disease of Narcissus bulbs which has come to receive the name of “basal rot” is caused by an active injurious fungus—viz., “*Penicillium*”—specific in the sense that it has a special affinity for bulbous structures; that it occurs always, if not altogether, in cultivated soils infested with the fungus, and where there are present free ammoniacal or nitrogenous compounds; that all injurious agencies affecting bulbs, such as frost, late planting, half-ripened roots, cause the bulbs to fall an easier prey to the disease; that healthy culture consists in choosing a mellow soil, free from nitrogenous compounds, or in rendering the soil mellow by first growing on it a crop which will free it of nitrogen (and perhaps the best crop for this is grass); that the disease may be warded off by allowing the roots to lie only sufficiently long to cover the growing or active stage; that they require deep planting if there is fear of disease; that they require plant food in the way of phosphates at planting and potash later on; and with all these, as a further precaution they may be surrounded in the ground by some agent that is known to be free from *Penicillium*.

“Home and Garden.”*

THIS is a book over which the appreciative reader will gladly linger, forgetting the toil and turmoil of everyday life, and even the reviewer may abate somewhat of his customary speed. It is one of the advantages of our numerous free libraries that books like the present, which otherwise could only be found in the homes of the wealthy, are brought within the reach of any ratepayer. Many a reader has little chance of imitating what is so happily described in these pages, still, even to him or her, its contents may bring pleasure, showing how delightful a home and its surroundings can be made. In an age distinguished by its tendency to seek enjoyment everywhere but in the home, we welcome every book which endeavours to give it new fascinations, and point out its neglected privileges. Someone has said that the word “home” is peculiarly English. Other languages have been explored in vain for its counterpart, still the foreign equivalent of “asylum” comes near to its meaning—a place that should afford a secure retreat, if possible. But it is rather pathetic that Miss Jekyll had to conclude her preface with a request that her friends, known and unknown, would allow her somewhat more of “peace and privacy.” Popularity may have its advantages, yet it also brings frequent sundry annoyances to the possessor.

Both Nature and Art are made contributors to the contents of this agreeably diversified volume, which proves the authoress to be a keen observer, and perceptive of the poetry which often irradiates what to the ordinary person is a commonplace object. Then the book is so full of kindness and healthy optimism that we feel there is some excuse for those who, knowing Miss Jekyll only by her pen, have wished to be acquainted with the scenes she has depicted, and the authoress too. The villagers casually mentioned, and the very wonderful pussies, seem almost to be friends of our own. Wisely, the locality is not indicated, but a passing remark leads us to surmise it is in Hampshire or in Sussex. To us, the interest of the book is largely in the chapters that discourse on wild or garden flowers, vegetables, and trees; still, those upon the house itself and the workshop appeal to all in some degree. Curious and beautiful again were some of the articles stored or on view in this home. One would fain admire the ancient tear bottles, the bronze or green coins, the Venetian glass, the Florentine stuffs, the embroideries of gold and colours, the rare English patchwork.

Many people, having verified the jocose saying that a house is an instrument of torture constructed by builders, have resolved to build one embodying their ideal. Two or three personal friends have done so; unfortunately, the result was less satisfactory than was expected, probably illustrating the risk of speculating where one has had no experience. Very likely Miss Jekyll's success is to be attributed to the fact that architect, builder, and owner worked together harmoniously, and she had first-class materials, which some amateur builders will not afford. Wood, chiefly Oak, grown close by; sandstone of the adjacent hills; bricks, probably such as no London builder could get; no wonder a good and secure house was erected, that might brave the centuries. Miss Jekyll allows, however, some excellencies to the London builder; he has method and precision, but his bricks are apt to be bad, his wood unseasoned, and he does not build substantially for the most part. “What's the good?” he would say, “you never know how soon you may have to pull it down.” One point to which Miss Jekyll gave special heed is constantly neglected. She had all fittings—for instance, the hinges, bolts, locks—proportioned

in size and strength to the material on which they were put. There may be pleasure found in both the sights and sounds of building operations, as Miss Jekyll suggests, but it must be under certain circumstances—not amid the clatter of suburban bricklayers and carpenters.

But we pass from the house to the woodland, since her chapter on a visit in April is appropriate to the season, though I doubt whether this cold spring, even in that locality, the wild flowers can be numerous. We may quote a part of the authoress's description of the Woodsorrel, a plant much in evidence recently, showing how minutely she observes. “The tender little blossom is about as white as the lightest part of a pearl. Its downy stalk is flesh-coloured and half-transparent, and the delicately formed calyx is painted with faint tints of dull green edged with transparent greenish buff, and is based and tipped with a reddish purple that recalls the veining of the petals. The brilliant yellow-green leaf is a trefoil of three broad little hearts, each joined at its point to the upright stalk by a tiny stalklet just long enough to keep the leaf divisions well apart.” Miss Jekyll names, among the flowers of April, the Violet, Primrose, Dog's Mercury, Cinquefoil, Stitchwort, Arum, and the Burdock, a plant she much admires, considering it worthy of a place in gardens. It has, she says, “a grand wave of edge and strength of line,” the grandeur of the Gourd tribe without their weakness. We have also noticed what a curious tangle of stems and branches a group of old Laurels will produce, as she has remarked, when left untouched in a shrubbery. Of course the species meant is the *Cerasus Lauro-cerasus*, not the Bay or true Laurel, but what the early botanists called the Bay Cherry. The Portugal Laurel has longer racemes, and is more erect in habit.

“The Garden of Wallflowers” is a chapter appropriate just now, but the authoress had not a garden all of them, only banks devoted to the forms she cultivates; associated with them are Vincas and Acanthus. But the authoress's idea of a Wallflower garden is that of one where many of them are grown upon walls, variously planned, as well as on banks. For contrast, she would add some patches of Tulips, Aubrietias, yellow Alyssum, *Corydalis capnoides*, and sundry others. It is, however, in the chapters on “Roses and Lilies,” “Briar Roses,” and “Midsummer,” that Miss Jekyll seems to be at her best, and these have illustrations that are specially attractive. A lover of all flowers, she gives the chief place to the Rose and the Lily, or such species as are so styled, if not in botanical strictness. To the Briars Miss Jekyll is partial, as representing old style garden plants; the Scotch, she says, have beauty nearly all the year. Of the many Briars grown nothing surpasses the double white Blanche de Coubert. After commenting on Lilies and Irises, Miss Jekyll remarks that some of the commoner kinds really have excellent qualities, *L. croceum*, for instance, which thrives in London; it is the Herring Lily of the Dutch, as flowering when the great hauls of herrings occur. By management it will make a grand show in the borders, like *L. tigrinum*. Referring to midsummer, she states that in her county its arrival is announced by the Elder bloom being fully out.

The chapter on “Trees and Lanes” appeals to our human sympathies, since the life of cottagers is touched upon, and we have portraits of Mary Huntingford and James Furlonger. That quaint old fashioned cottages, farmhouses, too, are often unhealthy we know. About Kent we see many samples of what Miss Jekyll depicts in her county. Bricks or boards in the lower floors laid flat on the earth, possibly with a green growth under them, low ceilinged rooms, above and below drafty or stuffy, roofs seldom sound, and drainage lacking; yet somehow people lived, even thrived in them. They had pure air, and, for ourselves, we would rather occupy such a cottage than an up-to-date London flat. But they might have given these buildings some slight elevation generally, sometimes they are below the level of the adjacent ground.

To the botanist a part of the above chapter will be acceptable, as it contains observations on methods of growth and development, also on the effect produced by the earth breaking away from the roots of trees. We might commend the chapters on rock gardens. That on “Plants for Poor Soils” and “Gardening for Short Tenancies” are replete with useful matter for gardeners. Again, there is in “Conservatories” many valuable suggestions. Thus the authoress plans out a series arranged according to temperatures—the outer houses in a circle for show, the centre for service. Much more might be made, she thinks, of the winter garden under glass—a place not without its flowers, but displaying chiefly species having handsome foliage, and kept at a temperature that persons could sit or walk about, and feel no inconvenience.

“The Kinship of Common Tools” is only a short chapter, yet it appeals to most of us workers, particularly in regard to the love we come to feel for an implement which is our constant companion, while it enables us to turn out some of our valued work. We must confess to a strong regard for an old penholder, which we have handled frequently during twenty years. From the authoress's name, we are tempted to conjecture she is of Scottish descent—one in the long illustrious roll of North Britain's devotees of gardening.

* Home and Garden: Notes and Thoughts, Practical and Critical, of a Worker in Both. By Gertrude Jekyll. London: Longmans, Green & Co.

NOTES & NOTICES

Recent Weather in London.—On Saturday and Sunday Londoners had apparently been dropped into the middle of June, for the heat was great. Overcoats were left at home, and straw hats became the order of the day. The nights continued moderately cool considering the heat of the day. On Monday and Tuesday though dull in the morning it became clear and quite warm later. Wednesday opened cold and wet.

Weather in the North.—With an occasional dull forenoon or evening the weather of the past week has been extremely fine for the season, the 19th and the two following days especially so. The wind set into the east on Saturday evening, and rain fell during the night. Sunday was dull; Monday brought alternately sunshine and heavy showers.—B. D., S. Perthshire.

Royal Horticultural Society of Ireland.—In your brief report of the spring show of the above society, I notice no allusion was made to the new double Violet, *The Countess of Caledon*, which was staged by Mr. Jeffreys, gardener to the Earl of Caledon, Caledon Park, Tyrone. It is much finer than *Marie Louise*, with greater substance of petal, and in shade a pale lavender or heliotrope. The exhibitor was awarded a certificate. Mr. Jeffreys' dish of Strawberries contained the finest fruits ever shown in Dublin. Several specimens weighed over 2 ozs., and six of them cleared the scales at 13½ ozs.

Sheffield Chrysanthemum Society.—Upwards of seventy members were present, at a recent meeting, to hear Mr. H. J. Jones, of Ryecroft Nursery, Lewisham, give an excellent lecture entitled "Chrysanthemum Culture on the Newest System for Growing Flowers for Exhibition." Mr. Jones spoke at some length on propagation, and recommended the cuttings to be inserted in boxes instead of pots, letting them have plenty of light and space at all times, and keeping them in a temperature of from 45° to 50° until ready for 3-inch pots. He considered that early varieties were best pinched the third week in March, and later ones the first week in May, giving preference to second crown buds. The lecture was most interesting.

Minnesota Horticultural School.—Minnesota now boasts one of the most complete horticultural buildings connected with a school or college in the United States. It was completed and occupied January 1st, 1900, and is connected with the Minnesota School of Agriculture and Experiment Station, St. Anthony Park. The building and equipment, according to "Meehan's Monthly," cost 67,000 dols., and consists of a main building, an annex for a greenhouse, laboratory, machine shed, about 4000 feet of glass, and a good nursery cellar. A large number of students can be accommodated. This term the classes in horticulture number 178. A very important feature of the school work consists of practice by the students of seed-sowing, transplanting, the growing of plants by cutting and grafting, the packing of nursery stock, pollination, testing of seeds, the making of Bordeaux mixture and grafting wax, and similar horticultural operations.

National Chrysanthemum Society.—The annual report and the schedules of the shows to be held during the coming autumn have reached us from the secretary, Mr. R. Dean, V.M.H., Ranelagh Road, Ealing. The report has already been dealt with in our columns, and we need therefore only call attention to the schedules at the present moment. The early autumn show will be held on October 9th, 10th, and 11th, and, as usual, the quality at this early date will be governed wholly by the season. The principal exhibition opens on Tuesday, November 6th, and continues over the two following days. This is invariably most excellent, and it is scarcely likely to prove an exception this season. Numerous valuable special prizes are offered for competition, in addition to the ordinary ones of the society. The president (Sir Edwin Saunders) offers a premier prize of £15 for a floral display of Chrysanthemums and suitable foliage plants, and other awards of £10, £8, and £6 will be given by the society. This should prove to be a splendid class. The dates chosen for the early winter show are December 4th, 5th, and 6th. Full particulars may be had from the secretary at the address given above.

Alexander College.—An effective piece of floral decoration was seen at this educational establishment on the occasion of the recent visit of some members of the Royal Family, and the Lord Lieutenant and party. The task of opening some new wings devolved upon H.R.H. Princess Christian. The various halls were decorated with Daffodils, the principal variety utilised being *maximus*, from Mr. Hartland, Cork, whilst Miss F. Currey, of Lismore, forwarded a choice collection of the leading types, which were suitably displayed in one of the class rooms. A handsome bouquet of Shamrock and white Narcissi was presented to H.R.H. Princess Christian.

Croydon Horticultural Society.—The schedule for the show of this society, which is to be held in the grounds of Brickwood House, Addiscombe Road, on Wednesday, July 4th, is now published, and may be obtained from the secretary, Mr. A. C. Roffey, St. Andrews Villa, 55, Church Road, Croydon. Particulars are given of upwards of 100 classes, embracing practically all the products in season at that moment of the year. Roses are always an excellent feature, and this year, provided we are favoured with a propitious season, will probably prove no exception to the rule. There are numerous local as well as open classes, and so far as can be seen provision has been made for all sections of growers.

New Ross Agricultural Society.—At a recent meeting of the New Ross District Council a motion was put forward tentatively, namely, the starting of an Agricultural Society for New Ross. As a result, a number of influential men assembled in the Grand Jury room, on April 19th, with the object of taking the necessary preliminary steps to bring the motion into concrete form. The chair was occupied by Captain Barrett-Hamilton, and after a brief discussion a committee was formed. The following consented to undertake the secretarial duties: Messrs. A. Tyndall, J.P., Ballyanne, and John Jeffares, Seark. Prior to the dissolution of the meeting it was unanimously decided that a general meeting be held in New Ross on the next fair day.

Linnean Society.—At the last meeting of this society under the presidency of Mr. C. B. Clarke, F.R.S., Dr. D. H. Scott, F.R.S., read a paper on "Sphenophyllum and its Allies, an Extinct Division of the Vascular Cryptogams." The author explained that his purpose was not to communicate new observations, but to give a summary of our present knowledge of the group and to discuss its affinities. He pointed out that the study of the Palæozoic flora not only greatly widens our conception of the three existing classes of Pteridophyta, but adds a fourth—that of the Sphenophyllales—to their number. The different views which have been held as to affinities of the Sphenophyllales were then discussed in the light of the results recently attained. The supposed relation to Hydropteridæ, though supported by some ingenious arguments, was rejected as baseless, and as inconsistent with the manifest Filicinean affinities of that family. The author came to the conclusion that the Sphenophyllales were most naturally regarded as the derivatives of a synthetic group, combining the characters of Lycopods and Equisetales, and indicating the common origin of those two classes.

Ipswich and District Gardeners' Association.—At a recent meeting of this association, Mr. Geo. Gilbert presiding, a paper on "Daffodils" was read by Mr. R. C. Notcutt, vice-president of the association. The paper was illustrated by a large selection of specimen blooms, a number of which had been kindly sent for the purpose by Messrs. Barr & Sons, T. S. Ware & Co., Ltd., and E. J. W. Disbrowe, of Bennington. The essayist commenced by giving some account of the history of the Narcissus, pointing out that it was quite a flower of antiquity, and well known to the ancients. Reference was made to the existence of the Daffodil in a wild state, over the whole of Western Europe. The classification of the flower next occupied the lecturer's attention, and the system introduced by Mr. J. G. Baker in 1869 was explained and discussed. Naturally the Trumpet Daffodil and its sub-divisions were dealt with fully, and fine examples of *maximus* and some interesting specimens of minor and the tiny *minimus* were shown. The concluding portion of the paper was devoted to what may be termed the practical side of the subject. An interesting account was given of the production of bulbs in a typical Lincolnshire bulb farm, the bulbs from which, the lecturer said, were often, in his opinion, better grown and in a healthier condition than those from Holland. Some useful advice was given as to the culture and treatment of Daffodils, with particulars regarding their favourite haunts and soils. At the end of the paper an animated discussion ensued, and the meeting was brought to a conclusion by a vote of thanks to Mr. Notcutt.

Manchester Show.—Messrs. H. Low & Co. write: "We notice in your report of the above show that our firm has not been mentioned as exhibiting. We had a small but choice collection of Orchids, which gained a silver medal, and the plants as under received awards as stated: *Cattleya Trianæ* Empress of India and speciosissima *Lowiae*, first class certificates; *Cattleya Trianæ cœrulescens*, award of merit."

Primrose Day.—On Thursday last London was a city of Primroses, and rarely indeed have such immense numbers been seen on the streets. In every direction the modest flower was in evidence. London salesmen speak of hundreds of thousands of bunches coming in, and yet there were not too many. Let us hope that the gathering of the flowers was not accompanied by mutilation or the destruction of the plants, which have been practically exterminated in one or two districts by senseless hawkers dragging plants as well as flowers from the soil.—J. J.

Guernsey Growers' Year Book.—A copy of this publication, which, as well as being a concise directory of the Channel Islands, is the official organ of the Guernsey Gardeners' Association, has just reached us. As has been the case in the previous issues, the book embodies much practical matter, which cannot be other than of the greatest value to all growers for market in the Islands. To a lesser degree they will also be useful to home growers, but for these the chief value of the book will lie in the fact that it contains such an extensive list of names and addresses. The price of the book is 1s. 2d., post free, and it may be obtained from the secretary, Mr. R. Marshall, St. Julian's Pier, Guernsey.

Kew Guild Dinner.—The members of the Kew Guild will dine together at 7.30 on Tuesday, May 22nd, in the Holborn Restaurant, under the presidency of Sir William Thiselton Dyer, K.C.M.G., C.I.E., F.R.S. The president of the Guild, Mr. G. Nicholson, A.L.S.; the vice-president, Mr. W. Botting Hemsley, F.R.S.; and other officers have promised to be present. A very large gathering is anticipated. Old Kewites who have not already procured tickets, which are 5s. each, are requested to make early application to the honorary secretary of the dinner committee, Mr. C. H. Curtis, 68, Whitestile Road, Brentford.

Easter Floral Fete at Wolverhampton.—By a happy inspiration the committee of the Wolverhampton and Staffordshire Auxiliary of the Gardeners' Royal Benevolent Institution conceived the idea of holding a flower show and musical entertainment at the Drill Hall in aid of the institution. The fact that it was an impromptu affair partly explains why the local gardening fraternity was so sparsely represented, and Mr. J. F. Simpson, gardener to Alderman C. T. Mander, the Mount, Tettenhall Wood, was the only exhibitor. Of the local trade also, remarkable to relate, Mr. Richard Lowe alone contributed, his examples being three groups of plants, in one of which were included numerous cut specimens of Orchids. The show was further augmented by groups of miscellaneous flowering and foliage plants, generously contributed by Messrs. James Veitch & Sons, Chelsea. Messrs. Dickson, Ltd., Chester, and Messrs. Webb & Sons, Wordsley. In the latter firm's exhibit a very fine strain of *Cinerarias* in pots was noted.—W. G.

Cleaning Nursery Stock.—We learn from an American contemporary that a bill is being prepared by the Western New York Horticultural Society, and will soon be introduced in the legislature, for the protection of the great fruit growing interests of New York and the eastern States from the spread of the San Jose scale. It is an amendment to the present law for the inspection of nurseries and orchards, and will require the fumigation of all nursery stock with hydrocyanic acid gas before it is sold. This gas when properly applied is fatal to the scale, as well as to all other insects, such as the woolly aphis, Peach and Apple borer and bud moth, but is not injurious in any way to the trees or plants which are subjected to it. As the introduction of infected nursery stock into neighbourhoods where the scale does not exist is the great source of infection, and the only dangerous source, except from natural means of dissemination, it behoves fruit growers to take active measures for the prevention of the spread of this dangerous insect and for the eradication of it where it does exist. Fumigation is a simple operation, and the cost is nominal. Under the proposed law nurserymen and dealers can give a clean bill of health to their stock, and the result will be a greatly increased demand for New York grown stock. Some nurserymen oppose in this form the bill, but its object should be favoured by all, while the details of the bill should be such as to accomplish the desired effect with the least expense or bother to either producers or consumers of nursery stock.

The Agricultural Board.—The manning of the new Board of Agriculture for Ireland is not yet complete. The trouble lies in the selection of inspectors. As yet, Mr. J. S. Gordon, B.Sc., late principal of the Agricultural College at Holmes Chapel, Cheshire, has been the only one elected.

A Remarkable April Day.—In London, on Saturday last, the thermometer in the shade rose to a maximum of 78°, the reading being 21° above the average for April, and 6° above the average for the two warmest months in the year, July and August. The occurrence of such heat in April is very unusual, though not quite unprecedented. During the past thirty years there have been four warmer April days; one of these occurred on the 20th of the month, in 1893, when the thermometer rose to 82°, the other three in 1874, when a reading of 80° was recorded on the 21st, and a reading of 79° both on the 23rd and the 27th. In twenty out of the past thirty Aprils the thermometer never rose as high as 70°.

Mr. S. Arnott.—From the following announcement it will be gathered that our talented contributor, Mr. S. Arnott, is appreciated in other walks of life as well as in horticulture. A meeting of Parish Council was held in Kirkbean on Tuesday, April 17th. There were present: Mr. A. Lewis Ligertwood (Chairman); Mr. S. Arnott, Carsethorn; Mr. T. Campbell, Southernness; and Mr. J. G. M'Myn, Kirkhouse; with Mr. H. Fulton, clerk and inspector. Mr. Ligertwood tendered his resignation as Chairman on account of his leaving the parish, and also resigned his membership. On the motion of Mr. T. Campbell, seconded by Mr. J. G. M'Myn, Mr. S. Arnott was unanimously appointed Chairman of the Council. He thanked the members for the honour they had conferred upon him, and proposed that the Council express their regret at the resignation of Mr. Ligertwood and their sense of his past services. The motion was unanimously agreed to.

Kingly Gifts.—We learn from a contemporary that H.M. the King of the Belgians has, by deed of gift, on his sixty-fifth birthday, made over to the Belgian State those of his properties which contribute to the charm and beauty of the localities in which they are situated. "Anxious to preserve for these properties their purpose of adornment, I have made it my constant care that they should not be spoiled by any building which might change their character. It would be regrettable if their purpose should be destroyed, after my time, to the detriment of the beauty and salubrity of various populous localities. Being persuaded that it is fitting these properties should belong to the nation, I have resolved to offer them to Belgium, and I beg you to submit the deed of gift which I attach to this letter. Close to large towns, above all, it is highly expedient to preserve open spaces with their natural beauties in the interest of the picturesque and of hygiene, and it is particularly so when these spaces are adorned with plantations already large, and laid out in lawns and gardens bordering on the boulevards. It is the continuance of this arrangement of these open spaces, which have cost the public treasury nothing, that I desire to safeguard in the future. However modest may be the works of embellishment which I have carried out, it is of moment that they should not be lost to future generations." The properties comprise the noble domain of Laeken, close to Brussels; the marine residence at Ostend, and the château in the Ardennes.

The weather during the first part of the week was dull and cold, with strong winds and frequent showers; the latter part was bright and very warm.

Phlox canadensis.

"FLOWER-GARDENER," on page 326, under the title of "Dwarf Phloxes," gives thoroughly deserved praise to a number of the best varieties in cultivation. It is to be hoped that your contributor's remarks may tend to popularise these beautiful plants, which do such a large share in adorning our rock gardens at various periods of the year. To those mentioned on the page quoted I would like to add *Phlox canadensis*, the beauty of which cannot be questioned for one moment. It is a dwarf-growing plant that produces a really surprisingly large number of flowers. The colour is one that is not particularly easy of description, and may perhaps be safely termed bluish lilac of a peculiarly shining hue. It thrives remarkably well in a pan, and becomes quite covered with its attractive flowers. In a mass in the rock garden, however, it is seen to the greatest advantage, and it is then admired by everyone who sees it. I have been told that it is then invariably satisfactory, and I should be glad to have the experience of other cultivators on this point.—F. R.

Planting Vines.

I HAVE read the remarks of "A. J., Moor Hall," page 310, on this subject, and think it will not be amiss if I give my views, derived from upwards of half a century's experience.

The Grape Vine starts naturally into growth in cool houses during April, and this is a good time for planting young canes. The borders for Vines generally may be partly within and partly outside, planting the Vines inside. For early forcing the borders are preferably inside, and internal borders only are best for Muscats. When the Vines are only required for producing summer Grapes the borders may be wholly outside. These are unquestionably the best for greenhouse Vines, as the rainfall, except in droughty periods, is ample for them. Extensive and expensive borders are altogether unnecessary where the natural soil is of a friable nature and well drained. Fertile garden soil will grow high quality Grapes, mixing with it some well decayed manure, and stirring to a depth of 2 feet. If the soil be rather heavy 2 lbs. of basic slag phosphate may be applied per square yard, and 4 ozs. of some approved mixture, such as Thomson's Vine manure.

In case of the natural soil being unsuitable, or a border has to be made, proper drains and outlets should be provided with 1 foot thickness of rubble about the size of half-bricks at the bottom and getting smaller to the size of road mettle at the top. It is best covered with a layer of old mortar rubbish, free from pieces of wood. Thirty inches depth of border is ample, and it need not be wider at the start than 6 feet. Good turfy loam taken from an old pasture where the soil is of a friable nature is the most suitable main ingredient for a Vine border. Of this a dozen barrowloads or cartloads, two of old mortar rubbish, one of wood ashes, and one of "nuts" charcoal, mixed together after chopping the turf into pieces forms a good compost, and should be placed in the border when moderately dry, and be made firm with the fork in preference to treading.

The Vines having been cut back in early winter, and kept in a cool house, will now have the buds grown to a length of a couple of inches. Turn them out of the pots, remove every particle of soil, preferably by washing with water at 110°, as this will disinfect them from phylloxera, if any, carefully preserving the fibres. Spread the roots out straight, covering them to the depth of 3 or 4 inches, working the soil well amongst them with the hand. Give a good supply of tepid water, and mulch with a little short, sweetened litter. If the canes have not been shortened it will not do to prune them now, but remove the growths from the upper portion down to where fresh shoots are desired to push, and cut away the disbudded part when the Vines have made some leaves, as there is then no danger of bleeding. Sprinkle the Vines and house twice a day, but avoid a very close and saturated atmosphere. Temperatures of 55° at night, 65° by day, and 70° to 75° with sun are suitable. If the weather be bright, and the panes of glass large, shade lightly from 9 A.M. to 2 P.M. If the temperature run up to 85° or more it will be an advantage. Where the Vines are planted outside the stems must be carefully wrapped with haybands, and the apertures in the wall be closed round them with elastic material.

When the Vines commence to grow give every encouragement, increasing the temperature to 60° to 65° at night, 70° to 75° by day, and 80° to 85° from sun heat. Young Vines of this year's raising may be turned out with the balls entire, or being in turves, which is the better plan, the soil should be well firmed about them so as to secure a fibrous root formation, and the house be kept at the temperature last named.—G. A.

Apple Norfolk Beefing.

BECAUSE this Apple is pronounced *biffin* in Norfolk, your correspondent "H. T. H." (page 329) thinks that name to be right and "Beefing" wrong. I am unable to agree with him or to accept Dr. Nuttall, who was not a pomologist, to Dr. Hogg who was, as the greater authority on the point. "H. T. H.," who has "known the Apple for over sixty years, has never heard it called Beefing by a Norfolk man." Neither have I, though I have only been acquainted with the Apple for about fifty-five years. It was not in Norfolk, and two Norfolk men in the garden always called the Apple *Biffin*, but as they called beef *bif* I did not regard them as authorities on orthoepy. Dr. Hogg distinctly states that the dried fruits are called *Biffins*, but explains that the name is derived from the similarity of the baked fruit to beef, and is "more correctly Beefing." The Dr., with whom I had a good deal of correspondence, was most careful in his nomenclature and spared no pains in his researches in the interests of accuracy. I did not, however, find any fault with the name "Biffin" as attached to dried fruits, when first referring to the subject; it is a good and well understood commercial term, but I drew attention to the inaccurate name "Beaфин," as applied to an English Apple in some catalogues, from which it had probably been copied by a correspondent, and gave him the proper name of the variety.—POMOLOGIST.

Judges and Judging.

As an official of a flower show, I have naturally read with interest the correspondence which has appeared on this important subject. While the societies which have plenty of funds, and can afford to pay for judges of the highest qualifications, would have little difficulty in securing new judges now and again, the smaller shows would not find it easy to make many changes. Good judges for small shows are not readily found, and officials are glad to know of suitable men who will come year after year, and whose decisions give satisfaction to reasonable competitors. I am aware that the view that there should be occasional changes is held by some of the judges themselves, but one usually finds that any change not due to the inability of the former judge to return is looked upon as a slight by some men of ability and high character. I daresay there would be some advantage now and again in making a change, but it would not always be for the better. There is a saying in Scotland which has a good deal in it, though expressed in a strange way. It is that "Ye'd better hae the deil ye ken than the deil ye dinna ken." It is sometimes better to put up with a few known evils than to run the risk of falling into worse. I think a good many others who have had experience similar to mine will be disposed to think it better to keep good men we know, while we can have them, than to get untried men in their places.—A SECRETARY.

The Gardeners' Royal Benevolent Institution.

"A. B." concludes his excellent leader, or pleader, if one may so term it, on page 300 by asking, "Who will not answer the call?" From the depths of my own experience and interest in the welfare of the Institution I venture to reply: The great majority of gardeners in the prime of life, the bulk of those a little beyond it, and with very few exceptions those who are farther on still, where, in "A. B.'s" happily expressed words—the hand trembles, and the eye becomes dim with the mist of years. These "will not answer the call." Why? may be asked. I do not know. In fact, does anyone know? For over a score of years it has been an enigma to me, and is likely to remain so to the end of the chapter. Did these men—good men and good gardeners we know they are—"answer the call," which has been so persistently shouted in their ears from the *Journal of Horticulture*, there would be no need for the special appeals made from time to time by those "above all pain, yet pitying all distress."

To many young head gardeners have I broached the matter. They would "think about it." To many an old head has the theme been diplomatically and delicately introduced. They, too, would "think about it." A fig for such thoughts which, like Turnip seeds kept too long, they hold in their bosoms until they are past sprouting into life. I now venture to sever the "not" from "A. B.'s" question and transform it to Who will answer the call? I look for an answer to this. I seek for it in the bothy, where the great future of gardening lies. In our boys of the bothy brigade is my hope, in them is my faith. They will answer the call, for not only is it the right thing to do, but theirs is the prerogative to do it at the right time. Perhaps it is a heavy call upon them and one would fain lighten it. Herein lays another question. Will not the executive of the G.R.B.I. meet them half-way by admitting them at a reduced fee on conditions that when filling the position of head gardeners they then become full subscribers? Surely this matter is worth its attention. Anyway, I sincerely believe that many of my dear young comrades of the craft will answer the call, and that they will not let the seed now sown lay in the cold soil of supreme indifference. Hurry up, then, boys, and still further increase the esteem in which you are held by—THE OLD BRIGADIER.

Notes on Gardenias.

THERE are few pure white flowers grown in our gardens and green-houses that receive a larger share of admiration than Gardenias, of which many thousands of blooms are yearly produced for the various markets. Unfortunately for producers for sale prices have depreciated during the past few years, and excellent flowers may frequently be bought from London flower sellers for 1d. each. This figure does not seem as though it would leave a very large margin of profit for the grower. It is not, however, proposed in these notes to deal with the plant from a market grower's point of view, but from the standpoint of the private gardener, to whom it frequently proves invaluable for various decorative purposes. But it is one of those flowers which, from the powerful fragrance they emit, have to be judiciously employed, as if too many are used in a warm room the scent, which in the open air would be termed delicious, becomes quite overpowering. It is not by any means unique in this respect, as such plants as Hyacinths and *Lilium auratum* are equally as troublesome to deal with, and one sometimes hears that the decorator is forbidden to use them at all. This is distinctly a matter for regret, as they are not easily replaced at certain periods of the year.

Gardenia flowers are, for one purpose at least, practically unrivalled, and that is for gentlemen's buttonhole bouquets. Not only have we a perfect flower, but also a particularly handsome type of foliage, so that no addition of foreign leafage is required whatever. Of course some gentlemen do not care for them, but generally speaking they are greatly appreciated, and we have not the slightest difficulty in utilising every bloom we can produce for this purpose and for use in wreath-making, for which they are invaluable. They have one very serious disadvantage, and it must always be kept in view when supplies have to be packed for transit by rail, and this is the liability to bruising. The very slightest rub almost invariably leads to the prompt appearance of a brown patch, which completely spoils the exquisite beauty of the flowers. Mishaps will occur at times, no matter how careful one may be in the packing, and it is very disappointing to have only half a dozen flowers spoiled. However, one is subject to this with practically all kinds of flowers to a greater or a lesser extent, and we must perforce do the best we can at all times and under all circumstances.

Fortunately the cultivation of the Gardenia does not present any formidable difficulties to the skilful plant grower, provided he has the requisite heat at command. They were not at one time regarded with a very favourable eye by gardeners owing to the partiality of the plant to become infested with insect pests, but now young stock is raised much more frequently than was formerly the case, and the trouble in this respect is thereby considerably minimised. True, the plants are attacked in many cases with equal frequency, but the practice of destroying the old plants has eased the grower's labour considerably, as they were by no means easy to get perfectly clean. When, however, young stock is mainly relied upon, and the methods of procedure are as good as circumstances will permit, there is not a great amount of trouble to contend with. So far as I have observed mealy bug and scale are the worst enemies to deal with, and the best preventive is undoubtedly excellent growth. Though plants may under exceptionally favourable conditions be had in flower over a considerable period, the natural flowering time is during March, April, and May, and at the present they are abundant. Most growers contrive to have blooms several weeks earlier than the date specified, and this can usually be done with comparative ease, but to much prolong the season, special conditions would have to be provided, and as a rule this is not possible, the majority of gardeners having their Gardenias in the stove in companionship with other customary occupants of that indispensable structure.

There are, I think, few plants that are easier to propagate than Gardenias, for cuttings can be rooted in small pots at practically any time of the year. In a compost of peat and sharp sand, the pots being plunged in cocoa-nut fibre refuse in a propagating case, roots are very quickly emitted, and good plants can soon be produced; in fact, I have known cuttings inserted in February as suggested to produce good flowers in the following spring. This express system is not always practicable, and August is usually found the most suitable month for propagation. Half-ripened shoots are then chosen, and these with the necessary attention to stopping and pinching will flower excellently in about eighteen months. The plants will not produce many flowers at one time, and they are somewhat fugitive;

but the succession will be continuous for several weeks, and the total number of blooms will be very large. As soon as the small pots are filled with roots the plants must be repotted, using a compost of loam, peat, and sand, and guarding most carefully against breaking any of the roots, which are decidedly tender. This fact must be borne in mind whenever the plants are repotted, as I have seen excellent stock almost ruined by carelessness in this work. The atmosphere of the house should be somewhat close at this stage, and the syringe may be advantageously used.

It will, of course, be essential to repot the plants as is necessary, always carrying out the operation before the plants become root-bound. They will eventually reach about 6-inch pots in the first year, and in these the plants will throw fine buds, which can be either removed or retained, according to personal requirements. The removal of the buds tends to improve the plant in habit and floriferousness, but they thus attain to a rather larger size than growers with limited space can comfortably provide. If they are finally placed in, say, 10-inch pots, they can be kept in the same receptacles year after year if desirable, but the difficulty of keeping them clean will present itself to the cultivator. When Gardenias are in good health and active growth they have a decided partiality for water, which must be abundantly supplied; this fact emphasises the necessity for perfect drainage prior to potting. Provide at the final potting, whether the plants are to be in 7-inch or 10-inch pots, a sound compost, preferably of fibrous loam and peat, with coarse sand for porosity, and a modicum of some approved fertiliser. Needless to say the latter must be judiciously employed, or more harm than good will be done. Liquid manure if used must be in a weak state, but as a matter of fact it is scarcely necessary at all if an excellent compost is provided.

There are several varieties in cultivation including *G. citriodora*, which is of dwarf habit and produces small flowers in the spring; *G. florida* and its varieties *Fortunei* and *intermedia*, and *G. radicans*. Of these *G. florida intermedia* (fig. 98) is decidedly the most popular, as being exceptionally free flowering and of an attractive habit of growth. The others named are comparatively seldom found in private gardens.—F. ROWE.

New Type of Pelargonium.

PROBABLY the sequel to the above heading will somewhat disappoint the expectant reader when it is explained that it refers to a type mentioned in the *Journal of Horticulture*, January 7th, 1875, by M. Jean Sisley, of Lyons. It was raised by M. Ch. Huber, florist of Nice, who was to send it out in the following March under the name of *Geranium pseudo-zonale*. Since then, however, so far as I am aware, no further mention in the horticultural press or otherwise has been made pertaining to it; but, according to the flattering description of its attributes, I have thought it would be interesting were it possible to obtain some further information regarding it.

M. Jean Sisley's interesting description of the type in question is worthy of repetition, especially from the hybridist's point of view, and I have given an abridged transcription. "Those who are occupied in hybridising know the hybrids of *P. hederæfolium* and *zonale* obtained in England by Wills and Peter Grieve by artificial fecundation. They also know that these hybrids seem to corroborate the theory of certain botanists, seeing that those that we know, and particularly *Willsi*, *Willsi rosea*, *Emperor*, and *Dolly Varden* are sterile; and that, which is much more to be regretted, is that they are superior to *P. peltatum* and *lateripes* by their great vigour and abundant blooming. The horticultural world will, therefore, learn with pleasure that a plant of this strain, which produces an abundance of seed, has been found in the environs of Nice, in a bed planted with *P. hederæfolium*, having lilac-white flowers, and *P. zonale* with red, white, rose, and buff. Apparently a good hybrid between the two species, but tending by its habit more to *hederæfolium* than *zonale*, as it is decumbent. Nevertheless, the foliage is more in the way of *zonale* than that of the hybrids obtained in England. The flowers are red, brilliant, and fifteen to twenty in a truss. The *zonale* has, therefore, exercised great influence in the fecundation. Which is the plant which has produced the seed whence this remarkable and curious plant has come? We do not know, and perhaps never shall know. By judicious crossing a new section in the numerous family of *Geraniaceæ* may be created."—G.

* Shows lasting two days. † Shows lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear in an early issue.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Chemical Fertilisers for Roses.

PROFESSOR WM. STUART, of the Experiment Station, Lafayette, Ind., who has been conducting some exhaustive experiments, summarises the results as follows:—“There is every reason to believe from the results obtained in the several experiments enumerated, that chemical fertilisers when properly used may be made to serve every need of the Rose plant so far as food is concerned. The use of raw bonemeal in every instance gave an increased yield over that of the control plants, as well as giving a greater percentage of gain than did those receiving other forms of phosphoric acid. Pure bonemeal is not injurious to Rose plants, even when applied in amounts largely in excess of the requirements of the plant. The acidulated bonemeal which has been used by florists and supposed to be harmful, did not produce any noticeable injury, even when used in large amounts. As a rule, a combination of phosphoric acid and nitrate of soda gave better results than one of phosphoric and muriate of potash. Two or three applications of potash during the season was found to be preferable to a single application, although in some instances no injury from the single application was apparent. A larger number of *Perle Ros*s were produced from plants grown in a black than in a clay loam, while the *Kaiserin* gave reverse results. The sub watering method proved an efficient means of supplying the plants with moisture.”

Roses from Cuttings.

I HAVE read with much interest the notes by “R.” (page 336) on Tea Roses, especially the reference to raising stock from cuttings. As I have been very successful in this form of propagation I will give my methods as briefly as may be in the hope that they will prove of assistance to my brother growers. I should like to see even more interest taken in Roses than is the case at present, for though they are, so to speak, everybody’s flowers, one too frequently sees them in wretched health from attacks by green fly or faulty methods of cultivation. Roses are essentially plants that require good treatment, and if this is not afforded they will never be perfectly satisfactory. But to return to the cuttings.

That Roses from cuttings succeed admirably admits of no doubt whatever. A practically unlimited number of plants can soon be raised by this means at various times of the year when suitable cuttings can be secured. One of the periods when they are almost sure to root well is early in May, as after the forced plants have flowered and the wood has become partially ripened, two cuttings can be taken from each well grown shoot without injuring the plant in the least. Shoots cut so that two joints are above and one joint below the soil when inserted, are all that are necessary. Cut the bottom leaf off the cuttings and place about five cuttings in one 3½-inch pot,

pressing the soil firmly. The most suitable compost consists of two parts of good loam to one of leaf mould, with a free admixture of sharp sand, placing some of the latter on the surface to be carried down to the bottom of the hole made to receive the cutting, as roots are more quickly formed in sand than in soil. If the soil in the pots is watered prior to the insertion of the cuttings the work can be done much more firmly, and the cuttings stand a far better chance of rooting than they do in a loose dry soil. In either case water should be applied to settle all properly down.

Place the pots in a gentle bottom heat in either a hotbed or a propagating frame, whence the cuttings can be kept close except for the admission of air occasionally for the evaporation of condensed moisture. On no account must the foliage be allowed to flag, therefore shade when necessary, and occasionally sprinkle the leaves with water. Roots will quickly form, when the plants must be removed to a warm house for a time, giving them a position near the glass to prevent their being drawn during the growth. Place them singly into small pots, using a similar kind of soil, returning them to their former quarters until established, when the plants should be gradually hardened, and either placed out into their permanent positions or be kept in pots for the remainder of the season. If the latter system is to be adopted a shift into 4½-inch pots will be an advantage, using soil with more loam and some partly decayed manure, plunging the pots in ashes for the remainder of the year.—GROWER.

Scarlet Runner Beans.

It is seldom of any use to sow seed of Beans before the end of April or the beginning of May. Even if the weather is genial and warm earlier than the dates named there is no guarantee that it will remain so throughout the month of May. Frosts during the middle of the month are always likely to occur, and Beans are even tenderer than Potatoes, and less able to recover from injury caused by frost; besides, should the growths recover, a check has been given the plants, and time has been lost. There is the same liability to frost in the south as in the north, though of course there are favoured places where May frosts do not trouble, and Beans may be sown earlier with prospects of obtaining a crop in advance. Cultivators who can afford space may try a row or two of early sown Beans, but not depending upon them for the main crop, which should be sown at the usual period early in May.

The best way of insuring an early crop of Runner Beans is to sow seed in boxes at the same time as sowing outdoors. These seeds will soon germinate under glass, but the growth must not be allowed to become drawn by staying too long in a warm structure. Immediately the leaves are forming place the box in a cool structure or in a frame where the growth will develop sturdily. The planting out may be done as soon as safety from frost is insured. Previous to planting the ground should be well prepared and the sticks inserted, placing one plant to each. Water in the plants and give one tie to each, so that the tendrils will soon seize hold of the stakes. Should the weather be hot and dry mulch over the roots with short manure.

The soil for Beans ought to be light, rich, well broken up, manured, and not of a wet character. It should not be deficient in lime or potash, and if there is any doubt on that score fork into the ground a dressing of lime, one bushel per rod, and sprinkle a liberal quantity of wood ashes along the rows and in the drills previous to sowing. This supplies potash. Ground that requires some additional enriching may, before sowing, be dressed with a mixture of artificial manure, consisting of 1½ lb. of salt, ¾ lb. of nitrate of soda, ¾ lb. of superphosphate, and ½ lb. of kainit. Apply this quantity to a square rod of ground.

Beans should be sown in double rows, 9 inches between the two rows. Place the seed 4 inches apart, 2 or 3 inches deep. The stakes may be fixed as soon as the plants begin to put forth their tendrils, a line of long, straight, smooth stakes to each row, tying them together near the top with a horizontal stake or rod. After this no further trouble should be taken except to afford water, mulching, and liquid manure as the flowers appear and pods form. Moisture at the roots at that period is very essential, as the flowers are likely to drop if the growth is not well supported. Copious supplies of water should be continued throughout the bearing season, especially if the weather is hot and dry. Beans, however, abstract a large amount of moisture from the soil, and making good the deficiency is a necessity even in the dampest weather when the crop is growing in very light dry soil.

To prolong the supply of Beans it is important that the pods be gathered as soon as ready. This will prevent the maturation of seed, which is an exhausting process.—E. BARROW.

The Sleep of Plants.—The "sleep" of plants is by no means analogous even to that of animals. It is a popular name given to the phenomena of sensitiveness to light, humidity and heat. When leaves go to sleep, they reduce sail to meet conditions, they expose as little as possible of their surface to radiation. With flowers sleep or closing usually has reference to pollen protection.

Narcissus Sir Watkin.—Seldom have the flowers of this splendid variety been better than this year. We have a considerable number planted in various positions, and, without an exception, the bulbs have produced flowers large in size, of fine substance, and wonderfully rich in colour. It cannot be regarded other than as one of the most valuable Narcissus in cultivation. It differs from some others of the incomparable section in the boldly striking manner in which the flowers look up at one from above the broad green leafage. Like the majority of Narcissus it is simply invaluable for cutting, especially if the blooms are taken before expansion, and this means they will last for a very considerable period if fresh water is provided daily.—F. R.

Lettuce Stanstead Park.—For winter or rather spring supplies this is a good variety, and one better adapted for autumn than summer sowing. This was pointed out to me recently by a neighbouring gardener, and while in his case the varieties had been sown and planted last autumn, only this one remains, the others—Bath Cos and Moor Park—succumbing almost to a plant to the wintry weather experienced. These results are somewhat at variance with my own experience, Bath Cos and Hardy Hammersmith coming out of their trials better than could have been expected. Hicks' Hardy White, usually a reliable variety, did not do so well, thus showing that the results obtained in one season are not always guaranteed for the next, and proving, too, the mistake of depending entirely on one variety.—S.

Violet Marie Louise.—Having heard of the success of Mr. E. Stubbs, gardener to Mrs. Hudson, Bache Hall, Chester, with Marie Louise Violets, I took the opportunity of paying a visit to this establishment in the early days of April. Although this is the first attempt that has been made with Violets here, the success attained has been all that could be desired. In six ordinary frames, each containing about two dozen clumps, there has been continuous cutting since the end of September, with the exception of about a fortnight's severe weather in January. The clumps, I learned, were planted early in September in ordinary compost, and with the exception of a little weak liquid manure applied in March, they have not had anything "strengthening" since they were put out. At the time of my visit I quite expected to see small flowers with short stalks, but instead the blooms were large, well developed, and with stalks averaging quite 6 inches in length. The value of these deliciously scented flowers during the winter months must be inestimable, and the culture appears to be so simple that no well-equipped garden need be without them.—GEORGE PAXTON.

Prunus Davidiana.—This is a very pretty early flowering species from China, and a near ally of the common Almond, though differing somewhat in the size and colour of its flowers. It forms a small tree about 20 feet high, of a rather slender, upright habit, and very quickly makes a handsome specimen if planted in good soil. Although not largely grown in this country, it is rapidly coming into favour on the continent, from its freedom of growth, earliness, and hardiness. While the opened flowers are injured by hard frosts, the buds do not suffer if not too advanced, as this year has abundantly shown, the time of flowering being usually the last two weeks of February; but this year it has been quite a fortnight later, and the buds were not injured in the least by the previous severe weather. It can be obtained in two colours—white and deep pink—under the names of var. alba and var. rubra, either of which is highly ornamental. If a few plants of each are placed together in a position facing south with a background of evergreens, a splendid effect can be obtained at very little cost, and with little trouble in keeping right afterwards. The flowers are somewhat smaller in size than those of the Almond, but are produced quite as freely. It can be easily propagated by budding or grafting on the common Almond.—C.

Rapid Vegetation.—Never probably has the leafing and blossoming of trees been more rapid than during the past ten days. Fruit trees have become wreathed with blossom by the magic of sunshine, after the prolonged dull weather and cold winds. In the suburbs of London many trees have changed from the swelling of buds on Bank Holiday into full leaf now. Some Horse Chestnuts made growths over 6 inches long in as many days.

Colour of Daffodils.—Where marked differences were noted in the colour of Daffodils analyses were made of the different soils in which they grew. It was found that the intensity of the colour increased with the percentage of organic matter, phosphoric acid, lime and peroxide of iron. It was not, however, determined, says an American contemporary, whether all the increase of colour was due to the presence of large amounts of these compounds or only a part of them.

Planting Osiers.—Though in many parts of the country Osiers are planted principally in November, the cuttings or slips from which they are propagated also admit, says the "Farmers' Gazette," of being put in during the current month. The positions best adapted for Osier beds are low lying lands situated by the sides of rivers or running waters, and if these lands are subject to being occasionally submerged by an overflow of a stream, or to be otherwise irrigated, so much the better. In preparation for the reception of the cuttings the land should be deeply trenched, and divided into beds 8 or 10 feet wide; between these beds there ought to be shallow open drains. The cuttings for planting should be from 12 to 18 inches in length, and taken from branches of two or three years' growth. These should be planted in lines 2 feet apart, and covered with 5 or 6 inches of earth.

At the Flower Market.—The flower market at Covent Garden and the shops in the central avenue, better known as "the grand row," were exceptionally busy from an early hour on Monday morning arranging and despatching enormous quantities of red and white Roses for display in connection with the celebration of St. George's Day. Large as was the supply the demand was even greater, English grown red Roses fetching wholesale from 4s. to 6s. per dozen blooms, while white Roses realised 2s. 6d. and upwards per dozen. In view of the national character of the celebration many of the leading merchants were selling no flowers which they cannot guarantee to have been grown in England—of course under glass—but in addition to this very large quantities have been received in the market from France, the Channel and the Scilly Islands, and the price of these flowers ranged from 1s. 6d. to 3s. per dozen. Numbers of ladies visited the flower market at a very early hour to make their own purchases, and the streets around Covent Garden were enlivened by parties carrying enormous bouquets of choice red and white blooms. Quantities of artificial Roses are also being hawked about the streets, and command a ready sale, the imitation being excellent.—("Westminster Gazette.")

Cape Fruit and Hailstones.—A resident in the Colony has sent us a copy of the "Cape Argus" of March 8th, from which the following extract is taken:—"It is greatly to be feared that the fruit export trade will come far short of expectations this season. This is unfortunate, for the exportation of Apples was beginning to assume fair proportions, and so many young orchards are coming into bearing that a steady annual increase of our output was confidently anticipated. The reason why so few Apples are likely to be exported this season is chiefly on account of severe hailstorms occurring just after the fruit had set. In some instances the trees were actually killed by the hail, while in most cases they were seriously damaged and the bulk of the fruit knocked off. Orchardists have, perhaps, more to contend against than the followers of any other rural industry. The insect and fungoid pests that attack their trees and fruit are legion, while their crops are, to a large extent, dependent on the weather. Even where provision has been made for irrigation, and a large number of orchardists do this, a single hailstorm may wreck the prospects of a whole season, besides injuring the trees to such an extent that it may take them two years to recover. Against a visitation of this kind no precautions can be taken, but the careful fruit grower is now able to deal thoroughly with most orchard pests. Times may come in future when orchardists will suffer severely on account of unfavourable weather, but none of our industries established in connection with the land have brighter prospects than Apple growing. There is an unlimited market in England for all the Apples we can produce, and an Apple orchard in full bearing is a most prolific and profitable property to possess."

Ranunculuses.

THE Ranunculus is one of our most beautiful old-fashioned flowers, yet it is seldom seen, though very useful for cutting, being both a good traveller and lasting several days in fine condition. If cut whilst the buds are young or about a third expanded they will continue to unfold the same as if growing on the plant. A bed of the old florists' varieties is a sight to be remembered. Many persons, no doubt, are under the impression that the Ranunculus is rather fastidious. They want attention, I admit, but they only require ordinary treatment if the mould is suitable. Sandy clayey loam is the best soil, similar to that in which the common Buttercup grows freely, and if this flower flourishes in the district it may be taken for granted that the Ranunculus will thrive too if the following details are carried out.

Whilst growing the Ranunculus requires an ample supply of moisture, but it will not thrive in a close sodden soil. The position for the bed should not be in a high and dry place, or where the soil is not drained and in a well pulverised condition. The site of the bed having been marked out stir the soil deeply, and if it is poor I would sooner add some fresh loam than use manure; but if it is decided to use the latter, in the autumn cow manure should be dug in, not being nearer to the surface than 6 inches. The most suitable period for planting is any time after the middle of February, when the weather is favourable and the soil in a workable condition, and I should prefer to wait a week rather than plant when the ground is in a wet state.

When planting some people draw drills about 1½ inch in depth; but what we have found the quickest and best way is to make the surface of the bed level, placing an edging of thin-boards around the bed, the top edge of the board to be 1½ inch above the level. Instead of drawing drills press the tubers on the surface in rows 3 inches apart and 4 inches between the rows, covering each with a pinch of sand, which will cause them to turn out clean when the time arrives for lifting. When the tubers are all laid out the soil should be placed carefully over the tubers to the top edge of the boards, and levelled off firmly with the back of a small rake. If those growers who have hitherto planted Ranunculus in drills were to adopt this plan they would not regret it, and the tubers would all be of an uniform depth.

There is one point in the preparation of the tubers before planting that needs attention, and that is to soak them in water for about twenty-four hours. When this is not done the tubers are apt to force themselves upwards too near the surface, and often out of the ground altogether, which weakens them considerably, and if not detected at once they perish, this being the cause of many failures. Another cause of failure is through the tubers not being harvested carefully, or they are stored in a damp place. A blue mould or mildew will often appear amongst them, which, if not promptly observed, will soon cause serious havoc. If this should appear the tubers should be picked out at once and the remainder laid out thinly in a dry place.

As the young foliage appears above the ground all weeds should be removed, and on the first dry day loosen the surface of the bed with a small stick or fork, and press the soil lightly about the roots. All the treatment they require is to keep them free from weeds and to give them a thorough watering occasionally if the weather prove dry. A slight mulching with well pulverised manure would also prove beneficial and would lessen the want of water, keeping the roots cool. When the blooms commence showing colour take care that no water touches them, as the construction of the flower causes them to hold water, and if the sun happens to shine powerfully, the blooms would most likely be injured unless shading could be provided. As the blooms fade they must be removed, or the tubers may be weakened, and as soon as the foliage turns yellow and withers lift the tubers, clear them of soil and old foliage, and lay them out to dry in the open air out of the reach of sun, or, what may be better, in an airy shed. When perfectly dry store them away. If the tubers are left in the ground after the foliage decays they are apt to commence making fresh growth or roots, which weakens them considerably.

Though as florists' flowers strictly Ranunculuses have fallen upon evil days, many thousands are yearly planted in various gardens in

the country. As a rule growers select between the French, Persian, and Turban (fig. 99) types, each of which possesses some desirable attribute of form or colour that renders it worthy of inclusion in the garden.—A.

Electric Light and Liliun Harrisii.

THE florist will doubtless be interested to learn the results of recent experiments conducted by the writer with the electric arc light upon the growth and flowering of Liliun Harrisii. The bulbs, mostly five to seven, were potted in mid-October, removed to cold frames in late November, plunged in the solid bed in the greenhouse late in December, and the electric light started on the 1st of January. Up to this time the cultural conditions had been kept as uniform as possible, and the plants were divided up as evenly as could be judging from the development of the tops. At five o'clock in the afternoon the light, a globeless arc lamp, was started, and at six in the morning it was stopped. The bed was divided into three sections—one exposed to the full effect of the rays from the light, another still in the light but behind a pane of glass which cut out some of the ultra-violet rays, otherwise being the same as the first section; the third section was kept dark by means of an opaque curtain drawn across the house each evening when the light was turned on.

At the time the light was turned on the plants were very uniform in each section, care having been taken to divide up the less uniform ones among the different sections. In about six weeks differences commenced to appear, which became more pronounced as the experiment progressed. In the lighted sections the plants became leggy, the leaves very much curved, narrower than customary; a sallow green and far apart on the stems. Under the naked light these points were most noticeable. The plants in the darkened section were more stocky and robust, had a more pleasing appearance, better green colour, and seemed healthier and more evenly developed. After the formation of the blossom buds these differences seemed to increase less noticeably, but the buds on the plants in the naked light section began to develop an ugly brown streak or band from base to point upon the surface exposed to the light directly, generally the upper surface. This was of the nature of a burn, and grew worse as flowering time drew near. The petals so afflicted were much curved, more than is usual with healthy blossoms. In some cases the stripes were a full quarter of an inch wide. In the second section, where the light had first passed through a pane of glass, no such effects were observed, and, of course, none in the darkened part of the house.

The effect upon the time of blossoming was also marked. The first flowers opened in the naked light, four days earlier than the earliest blooms in the second section, and thirteen days earlier than flowers in the darkened section. They lasted, upon the average, nine days, those in the second section nine and half days, in the third or darkened one eleven days. These last, though later, were more robust, but somewhat smaller than the others, which, like the plants that bore them, were spindling, but, with the exception of the burned ones, not unsightly.

Fortunately for the experiment a plant with two remarkably evenly developed stems was found. This was placed so that the curtain could be drawn between the stems, thus shutting off the light from one of them. The other stem was in the second section under the light that came through the pane of glass. Another twin-stemmed plant, almost as well developed as the one mentioned, was placed in the naked light section, and the larger of the stems covered each night with a large Manila paper tube to keep it in the dark. In each of these cases the stem in the dark developed its flower a day later than the stem in the light.

Other plants of uniform development were selected from time to time, marked and placed in the different sections, with the results that those in the lighted sections were first to blossom, and that the plants under the naked light showed to a more or less degree the brown burn referred to above. Plants that were selected for this part of the experiment were carrying well-developed buds when removed to the lighted section. The ones under the strained light lasted as long—namely, eleven days, and were as well formed as the flowers grown in the dark; moreover, they were from one to three days earlier.

From these experiments, which have not been conducted for a long enough period to warrant definite conclusions, it is advised that the use of the arc light, in bringing Easter Lilies into blossom, should be attempted upon only a small scale commercially until more fully investigated. From the above work it seems likely that the light might be used to advantage after the buds are an inch long, in order to make them expand sooner than they naturally would, but the light should always pass through a glass globe before reaching the plants. Probably an opalescent glass would be better than the one used in these experiments; this, however, has not been determined.—M. G. KAINS (in the "Florists' Exchange.")

Fig. 99.—TURBAN RANUNCULUSES.

The Royal Horticultural Society.

Drill Hall, April 24th.

SELDOM has the incapacity of the Drill Hall been better exemplified than was the case on Tuesday. Every corner of the hall was packed with products in such a manner as to prevent the possibility of anyone properly appreciating the beauties of the exhibits. This was to a certain extent accounted for by the presence of the National Primula and Auricula Society, a report of whose show will be found on another page, but the fact remains that the accommodation of the Drill Hall is insufficient for the splendid shows of to-day. The Fruit Committee was not pressed, there being only four exhibits, including magnificent Lemons from Kew, Winter Orange Pears from Mr. Notcutt, and Cucumbers from Mr. Markham of Wrotham Park.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. H. Laing, H. B. May, G. Reuthe, G. Nicholson, J. H. Pitt, E. Molyneux, J. F. McLeod, C. R. Fielder, H. S. Leonard, J. Fraser, J. D. Pawle, H. J. Cutbush, R. W. Ker, G. Gordon, C. Jeffries, T. W. Sanders, E. H. Jenkins, C. E. Shea, E. T. Cook, J. W. Barr, G. Paul, C. Blick, H. J. Jones, J. Hudson, J. Jennings, W. Howe, and H. Turner.

Mr. R. Brown, gardener to Sir F. Tress Barry, Bart., St. Leonard's Hill, Windsor, exhibited a collection of fifty varieties of Camellias from plants grown out of doors. The flowers were of exceptional excellence, while the foliage was of splendid substance. Such an exhibit as this should do much to popularise those handsome plants for outdoor culture. Messrs. H. Cannell & Sons, Swanley, contributed a display of Begonias, amongst which were Gloire de Montet, Boule de Neige, Triomphe de Lorraine, all semi-doubles, and the brilliant Count Zepplin. Veronica Hulkeana and Primula obconica were also staged. Mr. G. W. Piper, Uckfield, sent a number of blooms of the beautiful Rose Sunrise, which is rapidly becoming so popular.

A large bank of Cineraria polyantha (cruenta hybrids) was arranged by Messrs. J. Veitch & Sons, Ltd., Chelsea. The plants carried splendid foliage and graceful heads of variously coloured flowers. This type of Cinerarias produces excellent material for cutting. Messrs. R. & G. Cutbush, Southgate, were represented by a group of Azaleas, mainly comprising varieties of the Ghent section. Many of them were of great beauty, and strikingly floriferous. A most handsome exhibit of Cinerarias was sent by Messrs J. Carter & Co., High Holborn. The singles indicated an excellent strain, not too dwarf, and carrying handsomely coloured and formed flowers in abundance. The double varieties also were good.

A most attractive group was that comprising pot Roses from Messrs. F. Cant & Co., Colchester. Needless to say the plants were excellently grown and carried flowers of fine substance. Many of the most popular varieties were represented. Messrs. J. Peed & Son, Norwood, arranged a group of Lilacs, Staphylea colchica, Azaleas, Clivias, Ribes, Laburnums, and others, the whole being tastefully displayed. Mr. D. Kemp, gardener to W. Bryant, Esq., Stoke Park, Slough, sent a number of Amaryllises, magnificent plants in large pots, carrying large numbers of spikes of finely formed flowers.

Roses in pots, trained in various forms, were arranged by Messrs. Paul & Son, Old Nurseries, Cheshunt. The plants of Psyche were superb, as were the many other varieties represented. A few hardy plants were also employed as an edging. Plants of Gillenia trifoliata (fig. 100) were most charming. Mr. J. Russell, Richmond, contributed a collection of Japanese Maples, but the position assigned to them was not favourable to showing their beauty. Mr. H. B. May, Upper Edmonton, had an artistic arrangement of splendidly grown plants of Crimson Rambler Roses, Hydrangeas, Caladiums, Spiraeas, with Clematis Nellie Moser and Marcel Moser, and Ferns.

Messrs. J. Laing & Co., Forest Hill, contributed a collection of flowering and foliage plants, including Ericas, Clivias, Begonias, Crotons, Dracenas, Palms, and others, all in good condition. The same firm sent also a semicircular group of Azaleas, Crimson Rambler Roses, Lilacs, Acers, Roses, and Clematis. Messrs. J. Veitch & Sons exhibited Lilacs, with Magnolias obovata Lenne, conspicua Norberti, Soulangiana, and stellata. Mr. W. Rumsey, Joyning's Nursery, Waltham Cross, sent some magnificent Roses, including Maréchal Niel, Niphetos, L'Idéal, and others. From the Royal Gardens, Kew, came Cineraria Lady Thiselton Dyer, a hybrid from C. Heritieri, and a blue garden form. It is a graceful and attractive plant.

Mr. W. J. Godfrey, Exmouth, showed Pelargonium Emannel Lias, a pretty rose and white variety. Messrs. R. Wallace & Co., Colchester, staged Muscaris, Irises, Fritillarias, and Erythroniums in variety. Messrs. W. Cutbush & Son, Highgate, were represented by Azaleas, Gueldres Roses, Staphylea colchica, Lilacs, Calla Elliottiana, and Palms. Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury, staged a dozen varieties of Cape Pelargoniums, all carrying flowers of great excellence. Messrs. Barr & Sons, Covent Garden, sent a number of Japanese dwarfed trees.

Irish grown Tulips, from Messrs. Hogg & Robertson, Dublin, made a really brilliant display, and was immensely admired. All the popular varieties were represented by flowers of exceptional excellence. Messrs. J. Veitch & Sons sent a small group of Hydrangea hortensis rosea.

ORCHID COMMITTEE.—Present: H. Little, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, J. Colman, T. Rochford, W. Cobb,

J. Douglas, H. T. Pitt, H. A. Tracy, E. Hill, J. W. Potter, F. J. Thorne, W. H. White, T. W. Bond, W. H. Young, H. J. Chapman, and J. Jaques.

Messrs. H. Low & Co., Bush Hill Park, arranged a handsome group of Orchids. Cattleyas were particularly prominent, while Odontoglossums were also excellent. Phalaenopsis Lady Rothschild is an attractive form, that was much admired. Mr. W. Whitlock, gardener to W. A. Bilney, Esq., Weybridge, staged some superb Dendrobiums, that made a bright show. Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent Dendrobium macrostachya, D. teretifolium, Cirrhopetalum fimbriatum, and Cattleya Schrödera. Messrs. J. Veitch & Sons staged Dendrobium Sosius, Lælio-Cattleya Wellsiana, Cypripedium Jocasta, and Zygocolax alba.

Mr. Robbins, gardener to W. Vanner, Esq., Chislehurst, sent Cypripedium William Vanner, while Sir J. Miller, Duns, N.B., showed Lælio-Cattleya Lady Miller. Mr. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill, exhibited a miscellaneous group of Orchids, including representatives of many of those now in flower. Mr. W. H. Young,

FIG. 100.—GILLENIA TRIFOLIATA.

Orchid grower to Sir F. Wigan, Bart., Clare Lawn, East Sheen, contributed Cattleya Mendeli, C. Schrödera, C. Schilleriana, C. intermedia superba, Lælia Jongheana, L. Latoua, a superb white Cattleya intermedia, and a few others. Mr. W. Stevens, gardener to W. Thompson, Esq., Stone, Staffs, exhibited some Odontoglossums of exceptional excellence, two of which were specially honoured and are referred to below. There were several other growers who contributed small exhibits, including Messrs. de Barri Crawshay, N. C. Cookson, and J. Colman.

NARCISSUS COMMITTEE.—Present: J. T. Bennett Poë, Esq. (in the chair); with Messrs. C. Macmichael, G. T. Titheradge, R. Sydenham, J. Boscawen, A. Kingsmill, W. Poupart, P. R. Barr, W. Ware, J. Walker, G. H. Engleheart, S. A. de Graaff, J. Pope, W. Goldring, C. Scrase Dickens, S. Eugene Bourne, and Miss Willmott.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, staged a table of Narcissi arranged with Palms, and a front of Isolepis and Panicum. The chief varieties were Empress, Emperor, Sulphur Phoenix, Victoria, Apricot, Samson, Gloria Mundi, and W. P. Milner. Messrs. Jas. Veitch and Sons, Ltd., Chelsea, arranged a large table of Narcissi with Adiantums and Pterises in relief, making a pleasant groundwork. The collection included most of the well known forms, the chief were

Madame de Graaff, Mrs. Thomson, Mrs. W. T. Ware, Silver Trumpet, Glory of Leiden in fine form, Victoria, Cernuus, Duchess of Westminster, Madame Plempe, and Chelsea Gem.

Messrs. R. H. Bath, Ltd., Wisbech, also had a grand table of Narcissi tastefully arranged with their own foliage. The collection was beautifully clean throughout, and the blooms remarkably fresh. The most noteworthy forms were Victoria, Barri conspicuus, Wm. Goldring, Horsefieldi, Madame de Graaff, Madame Plempe in splendid form, as was also the Glory of Leiden, Weardale Perfection, Flora Wilson, and the Hon. Mrs. Barton. Messrs. M. Van Waveren & Son, Hillegom, sent a collection of Daffodils that included some remarkably fine forms. The premier variety was named Van Waveren's Giant, a magnificent Daffodil, by far the largest yet seen; other notable forms were Longfellow, Shakespeare, Surprise, Windsor Castle, Alaska, Olympia, and Aurora.

A pretty and attractive collection of hybrid and seedling Narcissi was staged by the Rev. G. H. Engleheart, Appleshaw, Andover. The chief varieties were Sol, Ariadne, Lillian, Flambeau, Landor, Virgil, a lovely form of Poeticus, Diana, Hector, Chancellor, and White Queen. Messrs. Barr & Sons, Covent Garden, arranged an extensive display of Narcissi in all sections. The chief varieties were Queen of Spain, Chaucer, General Roberts, a grand form; Weardale Perfection, Constance, Cernuus, Catherine Spurrell, Matron Vincent, Madame de Graaff, and Wm. Goldring. Messrs. G. Jackman & Co., Woking, Surrey, contributed a display of hardy flowers, of which Narcissi formed the backbone. The exhibit was a particularly attractive one, and it was unfortunate that it was in an inconspicuous position.

AWARDS.—*Floral Committee.*—Silver-gilt Flora medals to Messrs. H. B. May and Paul & Son; silver Flora medals to Messrs. W. Rumsey and F. Cant & Co.; silver Banksian medals to Messrs. J. Laing & Sons, J. Veitch & Sons, J. Carter & Co., Hogg & Robertson, R. Brown, W. Kemp, J. Russell; bronze Flora medal to Messrs. W. Cutbush & Son; and bronze Banksian medals to J. Peed & Son and G. Jackman & Co. *Orchid Committee.*—Silver Flora medals to Messrs. W. A. Bilney, H. T. Pitt, and W. H. Young; and silver Banksian medal to Messrs. H. Low and Co. *Narcissus Committee.*—Silver Flora medal to Messrs. R. H. Bath, Ltd.; and silver Banksian medals to Messrs. H. J. Jones, Barr and Sons, and J. Veitch & Sons.

Certificates and Awards of Merit.

Auricula Celtic Ring (Barr & Sons).—An Alpine of good form and substance; the colour is sulphur yellow (award of merit).

Arabis albida plena (R. Wallace & Co., A. Perry, and Paul & Son).—This is a double form of the well-known border plant (award of merit).

Canna Secrétaire Chabonne (Cannell & Sons).—A handsome form with rich orange coloured flowers (award of merit).

Cattleya Schilleriana Pitt's variety (H. T. Pitt).—The lip and throat of this are superb; the colour is very deep crimson. The sepals and petals are very dark (first-class certificate).

Dendrobium Wardianum Fir Grange variety (W. A. Bilney).—A superb variety of the well known type (award of merit).

Mertensia virginica rubra (A. Perry).—A soft rose coloured form of a comparatively well known plant (award of merit).

Narcissus Van Waveren's Giant (M. Van Waveren & Co.).—This is a superb large trumpet variety upwards of 5 in. across. The perianth segments are pale yellow and the trumpet rich yellow (first-class certificate).

Narcissus Olympia (Van Waveren & Son).—This, too, is a magnificent variety. The broad spreading trumpet is rich yellow and the segments paler (award of merit).

Narcissus Wilhelmina (J. de Groot & Son).—A splendid bicolor. The immense trumpet is rich yellow, and the perianth segments creamy white (award of merit).

Narcissus Charles Wolley Dod (Miss Willmott).—This may be described as Sir Watkin with white perianth segments and a bright yellow finchriated cup (award of merit).

Narcissus Countess Grey (Miss Willmott).—A beautiful bicolor with a pale yellow trumpet (first-class certificate).

Narcissus Mrs. Berkeley (Miss Willmott).—A very pale Sir Watkin. The cup is cream (first-class certificate).

Narcissus Eleanor Berkeley (Miss Willmott).—A finely formed white variety of the large trumpet section (award of merit).

Narcissus Dorothy Kingsmill (A. Kingsmill).—A perfect bicolor, with a sulphur yellow trumpet; the perianth segments are magnificent (first-class certificate).

Narcissus Diana (G. H. Engleheart).—A beautiful variety. The segments are white, and the broad flat cup is pale yellow (award of merit).

Narcissus Chancellor (G. H. Engleheart).—A superb Sir Watkin, with paper white perianth segments and a bright yellow cup (award of merit).

Narcissus Virgil (G. H. Engleheart).—A splendid poeticus, with a magnificently coloured crown (award of merit).

Odontoglossum crispum Victoria Regina (W. Stevens).—A magnificent pale heliotrope variety with numerous large and small bright brown spots (first-class certificate).

Odontoglossum Andersonianum Cooksoni (N. C. Cookson).—One of the finest varieties that has ever been shown. The basal colour is pale primrose with abundant brown spots (first-class certificate).

Odontoglossum Wendlandianum Crawshayanum (de B. Crawshay).—Dull brownish rose is the prevailing colour in this variety, the sepals and petals being profusely marked with crimson brown. The lip is white with chocolate spots (award of merit).

Odontoglossum crispum The Earl (W. Stevens).—This is a superb form. The sepals are white, almost wholly obscured by brown. The petals are white with a few large brown spots (first-class certificate).

Petunia Charlotte (P. Erselius).—A superb double white Petunia; it is of perfect form (award of merit).

Rhododendron Abbeyi (G. Abbey, jun.).—A finely formed soft, rose hued variety that makes a handsome truss (award of merit).

Saxifraga aretioides (E. H. Jenkins).—A charming dwarf variety with hundreds of pale yellow flowers (award of merit).

National Primula and Auricula Society.

April 24th.

THE twenty-fourth annual exhibition of this society was held at the Drill Hall, Westminster, and proved to be one of the best of the series. The majority of the classes were well filled, and the quality of the plants above the average.

In the class for twelve Auriculas in pots, dissimilar, there were five competitors. The veteran Mr. Jas. Douglas, Great Bookham, secured leading honours with a choice collection, comprising the following varieties:—Mrs. Henwood, Marmion, Mrs. Potts, Cleopatra, Magpie, grand; Perseverance, Shirley Hibberd, George Lightbody, Olympus, Raven, Abbé Lizst, and Acme. Mr. W. Smith, Bishops Stortford, was second with good specimens of Jas. Hannaford, Cleopatra, Rachel, Mrs. A. Potts, and Mrs. Henwood. Messrs. Phillips & Taylor, Brockwell, were third with Marmion, Miss Barnett, Mrs. Phillips, and Mrs. Dodwell, good. Mr. A. Brown, Birmingham, was fourth; and Mr. P. Purnell, Streatham, fifth. For six plants, dissimilar, Messrs. Phillips and Taylor were first with six good specimens. The varieties were Rev. F. D. Horner, Mrs. Phillips, Miss Barnett, Geo. Rudd, Mrs. Henwood, and Acme. Mr. W. Smith was second with Mrs. Dodwell, Black Bess, and Ruby in good form. Mr. A. R. Brown was third, and Mr. P. Purnell fourth.

There were six competitors in the class for four plants dissimilar, but Mr. P. Hemnell, Winchmore Hill, was well ahead with good specimens of F. D. Horner, Heroine, Geo. Lightbody, and Acme; Mr. J. T. Bennett Poë, Cheshunt, was second with James Hannaford and W. Brockbank in good style; Mrs. Whitbourn, Ilford, came third; Mr. A. S. Hampton, Reading, fourth, and Mr. H. J. Heading, Catford, fifth, while Mr. R. Holding brought up the rear. Seven exhibitors staged in the class for two plants, and a good class it proved to be. Mr. Parsons, Reading, was first with excellent specimens of Heroine and Geo. Rudd; Mr. J. T. Bennett Poë, Cheshunt, was second, and Mrs. Whitbourn third; while Messrs. L. Brown, Brentwood, R. Holding and Williams followed in the order named.

Nine plants were staged in the class for a single green edged plant. Mr. P. Hemnell was first with Prince of Greens, a grand specimen. Mr. W. Smith was a good second with Mrs. Henwood. Third no name. Fourth Mr. W. Smith with Mrs. Henwood. There was a good competition in the grey edged specimen plants. The first prize was taken by Mr. Paul Hemnell with a good plant of George Lightbody. Mr. W. Smith second with a good plant of George Rudd, the same exhibitor was also a good third with Rachael. Mrs. Whitbourn was fourth with George Lightbody. Twelve entries represented the white edged specimen plants, a strong, representative class. Mr. W. Smith was first with a beautiful plant of Mrs. Dodwell; Mr. H. J. Heading was a good second with Heatherbell; Mr. J. Parsons third with Dr. Kidd, and Mr. Heading fourth with a good plant of Mrs. Dodwell.

There were fifteen entries in the class for a single self plant, but Mr. W. Smith was first with a gigantic plant of Mrs. A. Potts. Mr. Holding was second with the same variety, Mr. W. Smith taking third place with Black Bess, and Mr. P. Hemnell fourth with Heroine. In the class for fifty Auriculas, not less than twenty varieties, there were three collections. Mr. Jas. Douglas was adjudged the premier position with a capital exhibit. The chief varieties were Shirley Hibberd; Lord Roberts, Andrew Hiller, Monarch, Perseverance, Rachel, Ringleader, Abbé Lizst, Acme, Fanny Glass, Ruby, and Lancashire Hero. Messrs. Phillips & Taylor, Bracknell, were second, staging Acme, Mrs. Dodwell, Conservative, Ruby, Ariel, Mrs. Dodwell, Geo. Rudd, Rev. F. D. Horner, and Mrs. Henwood, while Mr. P. Purnell was third with plants that were rather drawn.

There was a good entry for twelve Alpines in pots. Mr. Jas. Douglas led the way with superb plants. The varieties were Minerva, Masterpiece, Diamond Jubilee, Perfection, Mrs. H. Turner, Firefly, Trilby, Urania, Lord Dudley, Duke of York (a grand variety), Herald, and Boadicea. Mrs. Whitbourn was second with good specimens of The Bride, Rosy Morn, Lord Roberts, Dean Hole, Apollo, and Innocence. Messrs. Phillips & Taylor, Bracknell, were third with plants carrying more trusses, but they were lacking in quality. Mr. A. R. Brown was fourth; and Mr. P. Purnell fifth.

There were seven entries for six Alpines, dissimilar. Again Mr. Jas. Douglas was successful with plants of splendid quality. The varieties were Urania, Defiance, Zingari, Perfection, Duke of York, and Firefly. Mrs. Whitbourn was second, staging Rosy Morn, Dean Hole, Innocence, and The Bride well. Messrs. Phillip & Taylor were a good third, and Mr. A. R. Brown fourth. For four Alpines, dissimilar, the

first prize was awarded to Mr. R. Holding for specimens of Dean Hole, Dr. Durnford, J. J. Keen, and a seedling. Mr. J. T. Bennett-Poë was second, staging Edith, Dean Hole, and two seedlings. Mr. G. H. Addey, Waddon, Surrey, was third, and Mr. A. Fisk, Leyton, fourth. For a single plant with gold centre there were sixteen entries. Mr. Jas. Douglas was first with Duke of York; Messrs. Phillips & Taylor were second with Mrs. Martin Smith; Mr. P. Purnell third with Dean Hole; and Messrs. Phillips & Taylor fourth.

There were only two entries for twelve Auriculas, Fancies, the first prize being taken by Mr. Jas. Douglas, with an interesting exhibit. The varieties were Alexis, Buttercup (good), Quakeress, Rolt's Green, Lucretia, Lycidas, Golden Plover, Belle, Poppoia, Urania, Golden Oriole, and Comus. Mrs. Whitbourn was second with a much weaker display; the best plants were Belle, La Reine, and Hebe. There were three entries for twelve Polyanthus, distinct, but Mr. Jas. Douglas was well ahead for the first place. The plants were large, with plenty of flower trusses, while the flowers left little to be desired. The second prize was awarded Colonel Dixon, Aske Hall, Chelford, for plants that were rather drawn, while Mrs. Whitbourn was third. Mr. Jas. Douglas was again to the fore for twelve Primroses in pots, with a fine variety of colours. Messrs. I. House & Son, Westbury-on-Trym, Bristol, was third with smaller plants.

There were two entries for twelve Primulas, distinct species or varieties. Here Mr. P. Purnell was the victor, with a capital display. The species employed were *Primula obconica*, *P. denticulata*, *P. rosea*, *P. floribunda*, *P. Sieboldi*, *P. frondosa*, *P. variabilis*, *P. pedemontana*, and *P. verticillata*, a very pretty exhibit; Mrs. Whitbourn followed with good plants of *P. obconica*, *P. Auricula*, and *P. hybrida*. The baskets of Primroses were bright and well arranged, Mr. J. T. Bennet Poë was placed first with a basket of well developed flowers in which yellow was the predominating colour. Mr. Jas. Douglas was second with an attractive collection, and Messrs. I. House & Son were third with a good variety. Mr. Jas. Douglas was awarded the premier prize for Alpines with Lieska, a very fine variety. Messrs. Phillips & Taylor staged the premier Show Auricula with Mrs. Henwood, a grand specimen. The Guildford Hardy Plant Nursery, Guildford, had a fine exhibit of Primroses, Auriculas, in all sections, and a few rock plants, the whole constituting a fine display, artistically arranged.

The Young Gardeners' Domain.

Calanthes.

THE deciduous *Calanthes* are most valuable for winter flowering; their graceful spikes of flowers are excellent for vases in the drawing room or for dinner table decoration, and the plants look very effective if dotted about in the conservatory. *Calanthes* should be potted about the end of March, when they are just commencing to grow, in a compost of equal parts of peat and fibrous loam, with half the quantity of leaf soil and dried cow manure, adding some small pieces of charcoal and plenty of silver sand. Clean 5 or 6-inch pots should be used, half filling them with crocks, and placing a layer of moss over them. The inert soil ought to be removed from the plants, and the old roots should be cut back to about 2 inches of the base of the pseudo-bulbs, as these, with a short bamboo placed in the centre of the pot, to which the pseudo-bulbs should be tied, will keep them steady until new roots have entered the soil. The base of the pseudo-bulbs must be level with the top of the soil, which should be half an inch below the rim of the pot, and not raised to a cone like the majority of Orchids.

When potted the plants should be placed in a warm Orchid house or stove on inverted pots, and be very sparingly watered at first, gradually increasing the supply. The syringe should be freely used to keep moisture between the pots, but care must be taken not to wet the foliage too much. *Calanthes* enjoy plenty of light, but they should be shaded from the direct rays of the sun. The temperature of the house ought to be 65° by night, and 70° to 80° by day, ventilating carefully on all favourable occasions. When in full growth *Calanthes* should be fed about twice a week with weak diluted cow manure and clear soot water alternately; a little Clay's manure diluted with water is also beneficial to them. If attacked by scale, it should be carefully removed with a brush and sponge; thrips must be looked for, and if it makes its appearance the house should be fumigated with XL All.

At the end of the autumn the plants will gradually lose their leaves. They should be gone over often, and the decayed portions removed with a pair of scissors. Water must be given more cautiously, gradually reducing the supply until the flower spikes have been cut, which is usually in November or December, when it ought to be entirely withheld, and the plants should be placed on a shelf in a house where a temperature of 58° to 65° is maintained, and where they will get a complete rest.

Some gardeners prefer to start their *Calanthes* into growth on a layer of moist sphagnum just before potting them, but this is not necessary if watering is very carefully done. The following are good forms of *Calanthes*:—*C. Veitchi*, *C. vestita luteo-oculata*, *C. vestita rubro-oculata*, *C. Turneri*, *C. Byran*, *C. bella*, *C. nivalis*, *C. Sedeni*, and *C. William Murray*.—F. W. P.

Hardy Fruit Garden.

Disbudding.—*Apricots*.—The growths on Apricot trees should be regulated, and eventually trained in a systematic manner, but without crowding. When the growths first push on the trees shoots are present in suitable and unsuitable positions, and, as a rule, are too numerous. A system of gradual disbudding will rectify this, commencing when the shoots can be rubbed off with finger and thumb. First deal with growths that have pushed in positions where they will clearly be of no use. These shoots are those below and behind branches. In the case of Apricot trees a good proportion of shoots which would, if allowed to extend, form foreright shoots, may be shortened back when they have developed three full-sized leaves. These shoots will then form artificial spurs. Some restrictions must, however, be made on the number retained, reducing them by early disbudding. In addition to artificial spurs Apricots produce natural spurs, and these are preferable to the others. In the case of laying-in young shoots the best placed are to be selected, the chief growths being those at the base of the present year's fruiting shoots, one on each being sufficient to retain for succession. There must, however, be a growth left at the extremity, in order that sap may be attracted to the fruit. Growth of opposite character, such as the very weakly and the unusually strong, may be rubbed or cut out early.

Peaches and Nectarines.—Although the disbudding of growths may be commenced as soon as they form, it is not imperative or desirable that the operation be completed immediately. Gradual removals are invariably better, especially when the temperature is low and growth does not proceed very rapidly. Remove first ill-placed growths, wherever situated, then reduce the number of the desirably situated, these being the growths on the upper sides of branches. Foreright shoots are, as a rule, not required, though a few may be retained, shortening them to the third or fourth good leaf, which will enable them to form spurs. Peaches and Nectarines bear best on the previous year's growths, hence the main object of disbudding is to secure the best successional growths, and a fair proportion of others for furnishing the trees, also to prevent overcrowding. Growth is made earliest and strongest on the upper parts of trees, therefore disbudding should commence there first, dealing with the weaker and lower positions last. The best placed shoot must be retained for succession at the base of the fruiting shoots, and another, forming a leader at the extremity, to attract a circulation of sap to the fruit. Vigorous trees frequently produce strong growths from latent buds in the old wood. These are termed robbers, because, being of such strong growth, they appropriate the sap to an undue extent, and do not form fruitful wood.

Plums and Cherries.—When trees are young and in a state of formation, disbudding as a means of reducing the number of growths is of great practical utility in insuring the proper distribution of suitable growths. Afterwards, when the shoots on permanent branches are too numerous, their early reduction by disbudding saves much subsequent time and trouble, and prevents overcrowding. Not only are young growths liable to be too rank, but clumps of spurs in a fruiting condition may prove to be more numerous than desirable. Morello Cherries require treating similarly to Peaches and Nectarines, but the growths retained may be more numerous.

Apples and Pears.—Disbudding is practised on these as a means of thinning out and removing superfluous growths. Established trees trained in restricted form, on walls, and in the open, are furnished with clumps of spurs, among which an unusually large number of growths start. These, if allowed to remain, spoil one another, and it is therefore best to remove a portion. If, owing to their elongated shape, the spurs have been shortened back, there will still be disbudding to be done, growths pushing from the hard wood. These must be rigidly thinned and carefully regulated in number, so that the sun can shine to their base and promote a firm, short-jointed, growth. Young trees may be largely shaped and trained by judicious disbudding in the early stages of growth.

Newly Planted Wall Trees.—Now that these have started freely into growth, and the soil about the roots has become settled, the branches can be trained in position. Water may be needed by the roots, giving them, if the soil is at all dry, a copious supply, and afterwards afford a good mulching of manure, which will greatly assist in retaining the moisture in the soil instead of allowing it to escape by evaporation.

Syringing Wall Trees.—Fruit trees on walls, especially stone fruits, are subject to attacks from insects sooner than in the open. One means of averting attacks from green and black fly is to employ the garden engine upon them in the early stages of growth, and thus wash off the pests before they become numerous. If insects are allowed to

obtain a foothold something stronger than water must be used. Tobacco powder may be dusted upon infested foliage, and washed off next day. A good insecticide consists of softsoap and quassia chips. Dissolve a quarter of stone of softsoap in 50 gallons of water, and to this add the extract of 5 lbs. of quassia chips, this solution being made by soaking the chips in cold water for the previous twenty-four hours. It may also be obtained by boiling the chips.

The advertised insecticides may be used with good effects, following the instructions offered for their preparation. As a rule they simply require mixing with warm water, and to economise the distribution employ a spraying machine.

Fruit Forcing.

Cherry House.—When the stoning has been completed the fruit will commence colouring, then syringing must cease, and not be had recourse to again until the trees are cleared of their crops. A good moisture, however, should be maintained in the house by keeping the surface of the border moist, or if the trees are in pots damping the floor two or three times a day. The temperature must not exceed 65° by artificial means, and 55° to 60° at night, with a little ventilation, increasing it at 65°, liberally at 70°, and not allowing it to rise above 75° without free ventilation, closing at 70°, subject to leaving a little air on constantly at the top of the house. The borders must not lack water, and liquid manure may be given to trees in pots. Aphides must be kept under, fumigation or vaporisation being the only safe process after the fruit commences ripening.

Cucumbers.—Attend to tying the shoots, stopping at one or two joints beyond the fruit, removing bad leaves and exhausted growths so as to maintain a succession of bearing shoots. Water plants in houses abundantly, and with weak liquid manure about twice a week, syringing the foliage and walls about 3.30 P.M., when the house may be closed. Preserve a night temperature of 65° to 70°, 70° to 75° by day artificially, 80° to 85° or 90° from sun heat, ventilating from 75°, being careful to avoid cold currents. Close sufficiently early to run up to 90°, 95°, or even 100°, with abundance of atmospheric moisture in the house. Sprinkle the floors occasionally with liquid manure in the evening, or a little sweetened horse droppings on the surface of the bed will supply ammonia to the atmosphere, nutriment to the soil, and encourage surface roots.

Pits and Frames.—Plants in these will hardly need shading as yet, but the foliage must not be allowed to flag. Use tepid water through a fine rose watering pot at about 3 P.M. over the foliage, a light sprinkling sufficing, closing the lights at the same time, but as the nights are as yet cold, be careful that the foliage becomes fairly dry before night. Close early, and employ a thick night covering. Maintain a good bottom heat by linings, renewing them as necessary. Pot or sow ridge varieties if not already done, keeping these and other young plants near the glass.

Melons.—As the fruits of the earliest plants increase in size the supports must be lowered or otherwise adjusted. Stop the laterals frequently, or thin them where crowded. Supply water or liquid manure liberally to plants on which the fruits are growing rapidly, but avoid excess of either, especially liquid manure, which may injure the roots, and the fruits in consequence will not finish satisfactorily. Plants coming into flower should only have sufficient water to prevent flagging, and a drier condition of the atmosphere is essential to a good set, especially in the case of very vigorous plants. Attend regularly to the setting of the blossoms, and stop the shoots one joint beyond the fruit when impregnated, removing all superfluous growths after the fruit is set. Avoid giving stimulants to plants until the fruit is swelling, when liquid manure may be applied liberally, especially to plants carrying heavy crops, continuing the supplies until they are well advanced towards ripening. Maintain a night temperature of 65° to 70°, 70° to 75° by day, and 80° to 90° with sun heat, closing early, when the plants may be syringed, except when in flower and the fruit ripening. If canker appear rub quicklime into the affected parts.

Peaches and Neectarines.—*Earliest Forced House.*—The earliest varieties are now ripening, and the trees should not be syringed, but the border must not be allowed to become dry. Syringing the trees in the morning has a less prejudicial effect than afternoon, but after the fruit commences ripening, water lodging on the surface is apt to cause the skin to crack, and fungi readily avail themselves of their opportunities, and impart a musty flavour, even when not of a parasitic nature, "spot" often resulting from water resting on the fruit for a time at this stage. As the fruit of the other varieties will not be ripe for some time yet, the atmosphere must be kept genial by sprinkling the borders and paths as they become dry, syringing the trees in the morning, and again when closing the house. The night temperature may be kept at 65° to 70°, but 5° less, though it will retard the ripening, will not tax the energies of the trees so much as the higher temperature. Leaving the ventilators slightly open constantly at the upper part of the house will be an advantage. In the daytime, 70° to 75° by artificial means, and 10° or 15° more with sun heat, will be suitable temperatures.

Trees Stoning the Fruit.—Avoid a high temperature and sudden fluctuations at this stage, not hurrying the trees; a temperature of 60° to 65° at night is ample, and 70° to 75° by day. A little air left on all night will prevent the deposition of moisture on the foliage to any

serious extent. Enlarge the openings when the sun acts on the house, yet without lowering the temperature, which should advance with the increased power of the sun, and a corresponding increase of ventilation. Fumigation or vaporisation should, if possible, be avoided. The former dries the atmosphere, and not infrequently cripples the foliage, when the fruit, from the check, may be seriously imperilled and fall. Early closing is an advantage, but it must not be done to the extent of undue excitement. It is also advisable to allow a little extra latitude to the growth, but on no account permit foliage to be made that must afterwards be removed in large amounts. The growths should be secured in position as they advance.

Trees Swelling their Fruit.—In the early stages, and up to the stoning process, the fruit swells rapidly. The swelling of the fruits is materially accelerated by the maintenance of a genial condition of the atmosphere and the means employed to secure a good root action, which is best effected by a judicious and gradual regulation of the growth by the process of disbudding and in thinning the fruits. These operations should be done carefully. The more vigorous the tree the greater the danger of the fruit being cast in stoning, and the evil is often aggravated by previously disbudding severely, which favours strong growth more than steady progress. Supply water thoroughly to inside borders when necessary, lay-in the shoots, so as to induce growth in proper direction, allowing room in the ligatures for the swelling of the growths. After the fruit has stoned it takes the last swelling, when the shoots should be well tied down, but a moderate extension of the growths will materially aid the fruit in swelling. Any leaves that shade fruit should be drawn aside or shortened, and fruits on the under side or back of the trellis be raised on pieces of laths placed across the wires, so that their apices will be exposed to the light.

THE BEE-KEEPER.

Swarming.

Is it an advantage to allow the bees to swarm? We take it for granted that the majority of bee-keepers who are readers of the *Journal of Horticulture* are anxious to obtain as large a surplus of honey as possible. We presume, too, that a great percentage of them keep their bees in the modern bar-frame hive. Where such is the case we answer the above query in the negative. We do not go as far as to say that it is not possible to obtain both swarms and honey the same season from a stock, but bearing in mind the fact that the honey flow only lasts such a short time, we do not recommend the system of encouraging swarms from frame hives. If an increase of stocks is desired a better plan is to divide them as soon as a stock is well crowded with bees.

If frame hives are used, holding not less than ten standard frames, they cannot reasonably be expected to be filled with brood and crowded with bees, this season, before the end of May. They may be assisted, although there are ample sealed stores in the hive, by giving them a small quantity of thin warm syrup daily from a bottle feeder. As soon as the weather becomes settled and warm a few inches of sealed stores should be uncapped every third day. The bees will then empty the cells, and the stores will be placed in various parts of the hive. As the bees increase in number, and cover the combs, the queen will utilise all the empty cells for rearing brood. If the sealed stores become short, feeding should be resorted to again. All that is required in uncapping the sealed stores is to bruise the surface with the point of a long knife. This can be done without removing the frames, which is an advantage, as the bees are not disturbed, and there will be no risk of chilling the brood.

Prevention of Swarming.

The difficulty many bee-keepers have to contend with is the prevention of swarming. They cannot obtain swarms when they require them, and when they are not required they have them in abundance. As shown in previous notes, some varieties of bees are troublesome in this respect. We find little difficulty in preventing swarming if our native black bees are kept and worked on rational lines. Bees do not swarm on the impulse of the moment; arrangements are made several days beforehand. The hive has become crowded with bees. Queen cells are formed, scouts are sent out in all directions to find a suitable place for their future home. When they swarm they usually cluster on a bush or tree within a few yards of their hive. If they are at once placed in a skep and shaded from the sun until all have clustered, they may at once be placed in a frame hive and shaded without any danger of their leaving the new home. But if they are allowed to remain on the tree where they originally clustered for any length of time, they will rise into the air again and

go straight to the place selected by the scouts, often a mile or more away from the original hive.

To prevent swarming, space should always be provided in advance of the bees' requirements. Only experience will enable the bee-keeper to know when this is required. Much will depend on the age of the queen, as when she is aged and not able to fulfil her duties the bees will often swarm, although the hive may not be half filled. When this takes place it will be found that several queen cells have been started in the original hive. Some of the young queens have been sealed over, and will hatch out in a few days. If the swarm with the old queen is placed in a separate hive she will probably lay a few eggs, and will then succumb. The bees will then raise another queen, but the stock will be weak and useless for that season. For this reason we recommend uniting all weak stocks at this season, as such colonies have usually old or unfertile queens.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Cypripedium bellatulum (J. C. S.).—On page 345 you will find an answer to your question respecting this handsome Orchid, which has been kindly provided by Mr. W. W. H. Young. This, we trust, will be of assistance to you and enable you to succeed with *Cypripedium bellatulum*.

Manure from Horses Partly Fed on Linseed (E. A. R.).—If the manure from horses getting linseed with their food does not contain a large proportion of the latter, or to such an extent as to render the manure close and soapy, it would not be spoiled for growing Mushrooms. The manure, we suspect, contains only the portions of linseed matter given occasionally to the horses as "mash," they in other respects being fed on oats and hay, also bedded with straw, so that the droppings will be of a relatively dry nature, a certain portion of litter being collected along with them. Such will grow Mushrooms, other conditions being favourable. If, on the other hand, the manure be of a soft nature, due to "mashing" the food, it may answer fairly well if largely admixed with short strawy litter; but, as a rule, such material is inadvisable for growing Mushrooms.

Suckers on Peach and Nectarine Trees (Nemo).—The specimens are not uncommon, especially on light soils, innumerable suckers springing from the roots in some cases, the cause generally being a peculiarity of stock in particular soil. The remedy is to carefully bare the roots in the autumn, and remove the suckers close to their origin with the main roots. During growth the suckers should be kept in check as much as possible, so as to divert the sap to the branches. In the case of light soils it is desirable to firm the soil well, or even add stronger. As the trees are old and large this is about all you can do, otherwise lifting is advisable so as to get at all the roots and cut off the suckers quite close to them, replanting in firmer and more substantial soil. We do not think the roots have been cut with a spade, though this is bad practice, and often causes the production of suckers. The suckers are very detrimental to the health of the trees.

"Mimosa" Flowering Outdoors (Miss).—The spray appears to be of *Acacia lophantha*, but much sturdier than usually seen in green-houses. We have no knowledge of this species thriving in the open ground in England. Perhaps some of our readers will favour with their experience.

Phaius Cooksoniae (Young Orchid Grower).—It is pointed out to us by Mr. Norman C. Cookson, the raiser of *P. Cooksoniae*, that the flower you sent, and which we described as a "poor form of *P. Cooksoniae*," is much more likely to be *P. Norman*, as the true *P. Cooksoniae* does not flower until May.

Leaves of Vine Shoots Blackened (R. A. C.).—The leaves are affected by what is known as "browning" or "brunure," caused by *Plasmodiophora vitis*. It is a most perplexing affection, being confined to the young undeveloped leaves, and sometimes destroying the points of the shoots. It has been attributed to a deficiency of lime in the soil, and a dressing of air-slaked lime has been attended with considerable benefit. We have also found dusting over the foliage with it of great advantage. Sometimes the blackening occurs without any determinable organism, the cause being ascribed to an atmosphere saturated with moisture and kept somewhat close and stagnant, so as to injuriously affect the young foliage and induce the blackening. This often occurs with many other plants as well as Vines, and probably has no connection with "browning" as caused by an organism. The prevention in such case is self-evident—namely, the admission of more air, and a genial condition of the atmosphere, so as to promote evaporation and healthy development of the young growths.

Leschenaultia biloba major (W. Raby).—This plant is one of the many that are nowadays seldom seen in gardens, whence they have been ousted by younger, but certainly not more beautiful, favourites. Messrs. W. Balcin & Sons of Hassocks Nurseries usually show a splendidly grown collection at the Temple Show, and may, or may not, do so again this year. It is a New Holland plant. *L. formosa* is

FIG. 101.—LESCHENAUTIA BILOBA MAJOR.

distinguished by the brilliant scarlet hue of its flowers, but *L. biloba* and the variety *major* (fig. 101) have much larger flowers, and of an exquisite blue tint that is always appreciated because it is so scarce. The plants succeed best in peat and sand with abundant drainage, and they require the temperature of a greenhouse. The greatest care is needed in supplying the plants with water, and they should have a position on a shelf close to the glass, free exposure to light being important. Our illustration fails to do justice to this plant.

Bullfinches and Sparrows Destroying Fruit Buds (H. T. H.).—We can sympathise with you, as for many years we had to wage a war yearly against the bullfinches, and found the most effective means for the Plum and Pear trees was trapping in the autumn and early winter, and in late winter and spring having recourse to the gun. The Gooseberry and Currant quarters were dressed with hot limewash, the

bushes being well coated with it on a fine day. It saves the buds from sparrows, and to a great extent, if not wholly, from the bullfinches. We have also found great benefit from running black thread all over the bushes so as to form large meshes. Mr. W. Taylor advised the following wash in the *Journal of Horticulture* as obnoxious to birds. "The ingredients are a quarter of a peck or more of quite fresh quicklime, a pint of sulphur, and 1½ lb. of softsoap. Choose lime that weighs very lightly, dip a few of the lumps in or sprinkle with water (hot water is the quickest in action), and place in a bucket or other vessel, sprinkle a little of the sulphur thinly over it, then add more lime, just damp enough to slake, then add more sulphur on the top of it, repeating the process till all the sulphur is used. When the lime is slaked it will be seen that the sulphur is quite dissolved, and is scarcely visible except in the dark colour it has given to the lime. The quantity of lime used is not important so long as there is sufficient to dissolve the sulphur. The softsoap should be dissolved separately, and afterwards mixed with the lime and sulphur, and sufficient water added to make three gallons in all. If the mixture is not thick enough to apply with a brush, clay or more lime may be added. If the glaring white is objected to mix soot with it. If mixed in the way I have described and applied in dry weather no amount of rain will wash it off; but if lime is used that has been some time exposed to the air the sulphur will not properly dissolve, and the first shower will wash it off. It is necessary to caution my readers against dissolving the sulphur in a house containing plants in a growing state, as the gas emitted will burn up every leaf just as completely as if fire had been used. I have, however, never found trees injured from being painted with this mixture; it is only the sulphurous gas that is dangerous, and that probably would not injure plants in a dormant state." The mixture may be dashed amongst bushes with a whitewash brush, or made thin enough to be passed through a syringe. Birds will not touch buds that are well coated with it. We have no experience of arsenic for the purpose you mention, and severely deprecate its use over fruit trees and bushes, not only as extremely dangerous to animal life, but also deadly to plants.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (G. S.)—*Dendrobium Devonianum*; thanks to your excellent packing the flower arrived in perfect condition. (M. F.)—1, *Veronica elliptica*; 2, *Cytisus racemosus*; 3, *Eupatorium odoratum*; 4, *Anemone nemorosa*; 5, *Saxifraga oppositifolia*; 6, *Iris fimbriata*. (C. S. B.)—1, *Diosma ericoides*; 2, *Sparmannia africana*; 3, *Dendrobium Wardianum*; 4, *D. luteolum*. (S. F. K.)—*Chionodoxa sardensis*.

Poultry Tormentors.

Now that the warmer days are at hand, and all things living are breeding and multiplying, there is great activity among creatures great and small on the farm. We are going to leave the creatures great and confine ourselves to the life history of creatures small; so small, indeed, that unless we are blessed with good young eyesight they might escape our observation altogether. We may see their effects, but miss them. We may say with truth we may feel their effects, for some of us have very sympathetic skins which resent the big red blotches caused by nefarious insects of different kinds. How one poor little flea will cause in some folks a complete upset to the system for hours. What a hunt till the tiny creature is fairly trapped and squashed, and what irritation it can leave behind! Of course, as some folks may be flea proof, so some fowls may be flea proof too! But there must be a cause for the scratching and pecking and ruffling of the plumes that may be seen in any poultry yard by the careful observer.

If we asked the majority of our readers to define a hen pest, the answer would be without doubt flea. The answer would be quite right, but also quite incomplete. The flea is there, cheerful and industrious, but he has company equally active and possibly more injurious. First in order comes the flea; there are several kinds of flea (we believe somewhere about twenty-two varieties), but the one we treat of is known as *Pulex Gallinæ*, a grand name for so small a creature. A well known patent medicine always heads its advertisements thus, "For the blood is the life." The flea thinks the same.

Framed with a sharp, piercing mouth, it feeds on the blood of its victim, be it *Homo* or *Gallinæ*, and returns punctually for fresh supplies. We all know what it is to be weakened by loss of blood, and a constant withdrawal of the "life principle" with the attendant irritation is not calculated to improve the health of the victim. The flea is a nocturnal visitant (need we dwell on that), and a fowl requires rest as well as creatures on a higher scale. The flea is the outcome of dirt, flourishes in dirt, is only happy there; remove the dirt, admit light, and the flea vanishes. Alas! our experience goes to prove that the dirty hen-roost is the rule rather than the exception; there is an idea that any sort of a building is fit for hens, and the "cleaning" which may take place once a year is, as a rule, very superficial.

If fleas were the only hen pest it would be quite bad enough, but there are two other varieties of parasites equally active and probably even more abundant. We refer to lice and mites. Of the louse family there are several varieties, which dispose themselves on different parts of the body, and all cause a violent itching and unrest; they feed on productions of the skin and fragments of feathers, and are invariably most active on unhealthy birds. The prolonged action of lice will of course cause unhealthy birds. Nothing can thrive when in a constant state of irritation. Here again the best cure is cleanliness—damp dirty runs, badly ventilated houses, are the grandest breeding places. It is a strange thing that light and air, Nature's best health givers, are so often denied to our live stock; indeed, it might appear to an unprejudiced observer that we go out of our way sometimes to exclude these grand preventives of diseases.

Next we come to one of the smallest enemies—namely, the vast family of mites, wee things, but most powerful for evil. Some live on the birds at night only, others take up their abode at the base of the feathers; others are of a burrowing nature, and prefer the safety of a home under the skin. Of these, perhaps, the most injurious, because the most abundant, is the red or common fowl mite. Blood is their desire, and it is not to be wondered at that fowls so infested cannot and do not thrive. They become dejected and emaciated, and thus are in a condition to readily fall victims to other and fatal complaints.

We have frequently seen the question asked, respecting a habit some birds have of plucking out their own or their neighbours' feathers. This has been supposed to be a bit of pure mischief, but, like many other mysteries, there was a reason close at hand if only looked for. There is a mite, *Sarcoptes lævis*, which lives and exists among the roots of the feathers. The bird not being able to stand the constant and intense irritation, naturally tries to remove the cause, and in so doing loosens and pulls out the feathers. Sometimes the kind office is performed by a friend with like results. It is not malice prepense, but merely a desire to be rid of a troublesome pest. Remove the pest and the feather plucking will cease.

Then there is the mite which hides under the scaly skin of legs and feet. This is a well known and common disease, but quite amenable to treatment. In fact, there is really no reason why vermin in any form should exist in the poultry yard. It all resolves itself into a question of dirt or cleanliness. Indeed, we might say dirt is among the primeval curses, and we do not yet thoroughly understand its far reaching nature. As the great fire effectually stayed the great plague, so a fire in the majority of hen roosts would be the best thing imaginable.

As this is not possible or practical, it remains with us to purify and disinfect to the best of our power. Dark and damp hen houses should be brightened and aired, all unnecessary lumber removed, and no accumulation of manure allowed to remain. We know it is the custom in some places to remove the manure once a year. There is nothing yet equal to good limewash, with which should be mixed a proportion of dissolved softsoap—quarter pound to each gallon. Every crack and crevice must be penetrated, and all the perches and wood-work treated to boiling water and softsoap, with an admixture of paraffin. Fixed nests are a great mistake; they are bad to clean, and prove ready sources of trouble. We prefer to have movable nests, that can be taken out and exposed to the influence of wind and weather.

Straw is the worst possible lining, as it encourages vermin. At the bottom of each nest should be sprinkled hot lime, or some disinfectant powder or preparation.

If fowls have access to plenty of dust they will keep themselves in a great measure free from parasites. Surely sand and road dust are cheap enough, and a slight sprinkling of paraffin adds much to the efficacy and little to the cost.

Sitting hens are often among the greatest sufferers from vermin. Sufficient care is not taken to let them have a wholesome nest, and during the period of incubation matters do not improve, for the hen will not leave her eggs long enough to allow of proper feeding and bathing. Indeed, we believe and are sure, in many a case where a hen "runs" her nest it is because the place has become perfectly unbearable, and there are limits even to the endurance of a sitting hen. Even supposing she hatches off her brood, they are born among an innumerable horde of creeping things, and thus begin life under most unfavourable conditions.

A grass sod, turf downwards, and hollowed out, makes the best nest, and the intended mother should be treated to a dressing of white precipitate ointment. Rub some under the vent, the head and sides, and then dust well with insect powder. Whether it would be possible to close all openings in a fowl house and then burn a sulphur candle we hardly know; certainly there may be houses where this could be done with good effect. The feather mite should be treated as soon as seen, and the infested parts rubbed with oil of cloves or creosote and lard, one part of creosote to twenty of lard.

As to scaly leg, the rough crusts must be carefully removed, and then a dressing of lard and creosote applied. Sulphur and vaseline are equally efficacious, and following this, in the course of a few days, should be softsoap and warm water. We have often urged the desirability of dipping all freshly imported sheep before allowing them to mix with the rest of the flock, and we now urge that all newcomers into the poultry yard should at least be examined before being turned down. We do not want to improve the breed of vermin by fresh blood, however much we may want to invigorate and strengthen our poultry.

Work on the Home Farm.

The heavy gale which has visited us since last we wrote has made havoc in the stackyards; freshly thrashed straw has been blown into the fields, and the roofs of corn stacks torn off or partly stripped, in spite of every precaution. The gale has been followed by thunder, and, as we write, a beautiful warm rain is falling and seems likely to continue. The vane points due south, and the farmer's heart is gladdened with the hope that the protracted period of his troubles and difficulties are at an end as far as they apply to pasturage for his stock.

During an Easter visit to North Notts we have had many opportunities of hearing farmers' views on the agricultural situation. Everywhere there is despondency. Not merely the old grumbling spirit which has been so often quoted, but something more deeply seated, a kind of hopeless fatalism. They see loss and possible ruin before them and feel helpless; the increasing price of labour is the last straw, and they see no hope of better prices for farm produce.

The constant remark is "What can we do?" They have lost part of their capital and have not sufficient to retire upon, so have to continue the unequal struggle. Wheats on the sandy forest soils are a full plant, but very backward, and the winds have cut the young shoots a good deal. Barleys are only just peeping, but all are now in the ground. Potatoes are still being planted, and seem likely to occupy a large acreage. Up-to-Date and Selected Giant are the almost universal varieties planted.

Young seeds are very bare as well as short of plant. Ewes are very poor, and, contrary to the general rule in such a warm forward district, there are no fat lambs, for they are not yet fat. The grass fields look green, but a lawn mower would hardly get a cut, and cattle are still in the yards. They must now go out as the weather is warmer, and they must crop the pasture as it grows. Grazing cattle are generally low in condition. There will be few half-meated or nearly fat beasts turned out to grass this spring, and there must be scarcity of good beef in June. All strong beasts should pay well for a liberal supply of cake, and especially those which are forward in condition.

Mares are foaling, and the number of casualties are quite up to the average. A dead mare, two dead foals, and a pair of twins also dead, all the property of friends and neighbours, make a long list so early in the season. Big and good town horses are now very dear owing to scarcity.

authorities, including reports of experts on the nature of the soil, and this being so most people would think it would be placed in concise and precise form before a meeting summoned for the purpose of ratification. That the assembled Fellows expected something of that kind was generally understood, and the absence of it afforded a tempting opportunity for expressions of opposition to the whole scheme. The discussion, such as it was, was based on generalities and possibilities, and it was not easy to see how it could have been otherwise under the circumstances.

It is not suggested that if anything like full particulars of the nature indicated had been disclosed there would have been no time-consuming arguments. The probability is there would have been. The argumentation, indeed, was undoubtedly increased because of the greater number of points open to discussion. It would have been better to debate a specific question than declamations based upon assumptions. Every substantial fact in connection with a public proposal may be legitimately and advisably opposed, always provided the opponents put aside ulterior objects. It was however quite clear that the criticism indulged in sought to secure the Society's interests. This was definitely stated, and fully accepted by the Chairman, though if one speaker had not specifically announced that there was no concerted or organised opposition to the project of a new garden anywhere, some persons present might have thought the contrary. The apparent unanimity of the opposition had far less of design than the instinct of self-preservation.

As to the discussion of any particular site, there was none worthy of the name. Limpsfield was the only place officially brought before the Meeting. This one of the leaders of the opposition unsparingly condemned, although he had not seen it. He moreover announced a much better site at Reading, which he also had not seen, but something like a momentary sensation was caused when it was found he had derived his information from a confidential letter. This elicited from the Chairman a statement not previously mentioned, that the Limpsfield soil had been professionally examined and favourably reported upon by Mr. George Bunyard and Mr. George Paul, who it will be conceded ought to know something of the requirements of fruit as to site and soil. In addition, Mr. W. Poupert, one of the greatest and best market gardeners in the world, and Mr. Edwin Beckett, whose competency as a vegetable grower and general all-round gardener is indisputable, had made careful examination and furnished reports.

It is right to say, however, that these reports were not read; nor in any other form, beyond the bare announcement, were they placed before the meeting. Possibly they may have been withheld with other matter not deemed essential for purposes of discussion with the object of saving time; but it is very easy to lose much more time than to save a little by any such methods of economy, as is not unlikely to be demonstrated before the new Chiswick becomes an accomplished fact. But while those authorities agree on the suitability of the soil, it must be admitted that Mr. Arthur W. Sutton in differing from them did not do so without great knowledge on the subject.

It may be well for the Council to recognise the extremely probable contingency that the Fellows of the Society will not be hurried over the important matter at issue. It is not implied that there has been any desire on the part of the Council to rush it through, but there does seem to have been a misconception of the feelings of the Fellows on the subject. It is altogether preferable that the interest in the Society's affairs at this juncture should be keen rather than lethargic. There is not likely to be any curtailment of this interest, and especially since a gentleman who lately sent in his resignation from the governing body has stated in the letter on page 379 that "there has been very little time at recent Council meetings for the discussion of the new gardens." Moreover this announcement came as a surprise to the Fellows assembled last week, that the lease of "Old Chiswick" has yet twenty years to run. Still no greater mistake could be made than that the twenty years should be held to justify a dilatory policy. The passing of every year, and almost

every month, will render more difficult the acquisition of land suitable as to position and price for the object in view.

No doubt a strong feeling exists in favour of a suitable building being erected in London for the Society's meetings, which have now grown into shows, in recognition of the centenary. But the cost announced of £40,000 was held to be insuperable, and the idea was put out of court without serious discussion, by the passing with practical unanimity of Mr. H. J. Pearson's resolution, "that the gardens be removed from Chiswick, subject to the Council finding a site which will meet with the approval of the majority of the Fellows." This is, in substance and effect, exactly what was before the meeting at the onset, and confirms the recommendation of the special general meeting of April 25th. Thereupon an appeal was made by the President to the Fellows to look out for sites wherever they may be, and furnish particulars of any that they may deem suitable. As matters now stand, therefore, the new garden question must be settled before the desired hall can be considered as a memorial celebration in 1904.

Reverting to the Limpsfield site, there was not lacking evidence of disquietude on the assumed co-operation of County Councils. It was not unnaturally felt that financial support rendered by public bodies would involve corresponding representation on the governing body of the R.H.S. The Chairman was able to assure the meeting that there was no question of the Society being financed in any such way as was imagined. Much more likely is it that if on an adjacent site a building were purchased by an educational body for the teaching, among other things, of scientific and practical horticulture, that an arrangement might be made of a mutually advantageous nature, yet on an independent basis, by which the college might be a source of annual income to the Society. This might be expected to be so if the new garden should be at Reading, where there is an excellent college with "horticulture" in its curriculum.

A rather curious idea seemed to be lurking in the minds of some of the Fellows, that a garden, to be "national" must not be in the south at all, but equally handy for northerners, westerners, and easterners to reach. With equal reason they might urge that Kew is not a "national" garden because situated in Surrey. That the "New Chiswick" must be not far distant from the seat of government is a matter of the most obvious necessity; it is the representation on its Council and Committees of provincial horticulturists who can attend that renders the society "national." If it can be made more acceptably so, by all means let propositions be advanced with that object.

Whatever may be the future procedure recommended, it would appear desirable that it be placed as clearly, if consisely, as possible before the Fellows, say two or three weeks prior to the meeting for discussion and ratification. On another important question—the new bye-laws—these are to be published as "suggestive" in a forthcoming issue of the Society's Journal. Cannot the proposals for a new garden and the salient facts on which they are based be similarly published? The statement and the decisions to follow would be of interest to the numerous Fellows who could not attend the meeting. Perhaps the Council will on reflection consider that the two subjects—the bye-laws and the garden—are too large for discussion and settlement at the same meeting?

Singular expressions were heard at last week's Meeting respecting Chiswick. One gentleman who said he "knew much about land," advised the retention of the old garden on the ground that the longer it was held the more valuable it would be to the Society. He evidently thought it was the Society's freehold and not the Duke of Devonshire's. Because he could grow Apples on the breezy heights of Streatham Hill, Chiswick—the fog and sulphuric acid trap—in the Thames Valley ought to be equally productive. With buildings on three sides and the fourth designed for another colony; with deep drainage all round its gravel bed, and thousands of chimneys pouring out noxious fumes for precipitation by fogs, the garden is dried out below and poisoned from above, and all the skill and money in the world could not make it like its once fine old thrifty self. Ah, 'tis pity, but pity 'tis 'tis true.

Odontoglossum crispum Victoria Regina.

DURING the past few years one of the most successful growers of *Odontoglossum crispum* has been Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs, whose collection has such an enviable reputation. At Walton Grange is found, in addition to numbers of superb varieties, such an excellence of culture, that the plants must be a constant source of delight, whether they are in or out of flower. One of the latest varieties to be shown before the Orchid Committee of the Royal Horticultural Society at the Drill Hall was named *O. crispum* Victoria Regina, of which a representation is given in fig. 102. The basal colour of this beautiful variety is pale heliotrope with traces of the more commonly seen white, and numerous large and small bright brown spots. The Orchid Committee recommended a first-class certificate for this plant.

Eriopsis rutidobulbon.

The singular rough purple brown pseudo-bulbs of this species distinguish it from any other Orchid, though an approach to it is seen in some of the *Pleiones*. It is not exactly a popular species, but is more frequently exhibited than formerly, and is well worth growing. The flowers are small, with yellowish sepals and petals margined with purple; the lip is similarly coloured. A position not far from the roof glass in the cool end of the *Cattleya* house should be chosen for it, and not much compost must be placed about the roots.

Epidendrum Parkinsonianum.

Quite a number of different names have been given this plant, and one meets with it occasionally under all of them. Recently I saw it in a Norfolk collection under the name of *Brassavola Pescatorei*, and though it was so called at one time, I believe, I know of no authority for the name. It is a rather shy flowering plant in some collections, but is very attractive when it does flower. Coming from various situations in Mexico, naturally it varies a good deal, and this may possibly account for some of the duplicating of names.

I have seen fine plants of it grown in baskets suspended from the roof of an intermediate house, where it usually takes a downward direction as soon as it reaches the sides of the basket. Its large, rough leaves indicate its liking for light, and though these keep a brighter green in a shady, warm house, such plants are unlikely to flower much, and it is better to keep it near the glass. For compost use equal parts of peat and sphagnum moss, and not too much of it, keeping the plants well up in the baskets. The flowers are of various shades of yellow, with green and white markings.

Notes on Culture.

The spring, so far, has been very trying, and now the change from cold winds and dull weather to an almost tropical sun will be felt badly by all plants under glass, and Orchids not less than others. Shading has been little used until now, and all of a sudden we have to rush into it on all hands. But if a little care is taken now the plants will reap all the advantage of the improvement in the weather without the check unavoidable in its absence.

It is only reasonable to expect that plants, after a long cold winter, are not in a fit condition to bear sudden bursts of sun, so although, so far, shading has been below the average, it must now be considerably above for the time of year, or mischief to the foliage is bound to be done. When plants have been newly potted this extra care is very necessary. Already, perhaps, rather severely checked at the roots, the plants must not be further weakened by damage to the foliage, or a condition of collapse might easily be brought about. *Cattleyas* and *Lælias* are especially apt to be injured now, light-loving Orchids though they undoubtedly are.

The value of winter cleaning is now very apparent, for in any plant or house where this was neglected there will be evidence of it, and unless the new growths are to be overrun, the defect must be made good at once, on the principle of better late than never. The silvery edged Stock seed scale will be especially busy after a week or two of this warm weather, and though more easily dislodged from his position than some others of his family, it is a foe of the first magnitude if overlooked or its energy underrated. A good plan to get rid of this pest is to fumigate one night and sponge the plant the

next day, repeating the fumigation a few days later to destroy any chance insects that may be left.

Thunias will grow rapidly now if placed quite in the eye of the sun in a well moistened atmosphere. So will *Dendrobiums* of all kinds, but the growth of these is more tender, and when young it is necessary to shade slightly. I have never seen *Thunias* injured by sunlight provided the atmosphere was moist. If growing in a house the least bit too warm for them this will be very trying now to *Cœlogyne cristata* and its varieties. It is impossible under such circumstances to prevent a little shrivelling of some varieties, and if a late batch is grown these especially should be kept as cool and moist as possible now. They illustrate exactly opposite conditions to the *Thunias* and *Dendrobes* in pots.

The splendid racemes of *Cymbidium Lowianum* are especially attractive when the flowers first open, before that delightful tint of colour disappears from the point of the lip. When it does so we should, if we considered the health of our plants, remove the spikes; but they will last for many weeks if left, and left they are in the majority of cases. So, too, with many of the finest *Oncidiums*; but these are not so long-suffering as the *Cymbidiums*, and often settle the question by shrivelling up and dying when too hard pressed. In all departments there is a waking into life as it were; the houses are

FIG. 102.—*ODONTOGLOSSUM CRISPUM VICTORIA REGINA.*

daily getting more and more gay with blossoms, and will do until midsummer, or after. In the flowering house an attempt must be made to so strike the happy medium with regard to atmospheric moisture, that the flowers are not injured by damp on the one hand, or the plants by opposite conditions.—H. R. R.

EUPATORIUMS AT EASTER—The tall-growing *Eupatorium odoratum* can be had at the Easter festival with a fair amount of certainty, where the conditions obtain for their growth and the means for hastening or retarding them as the season requires. As a conservatory plant *Eupatoriums* have a just claim for space, that is when the structure is of good size, and furnished with ground beds for the arrangement of pot plants. They are too tall for stages generally, but as most conservatories and corridors have some ground space, their growth should be more generally adopted than appears to be the case. They can be grown in fairly large pots or restricted to small ones, the most important condition being a regular water supply. This is necessary because of their freedom in rooting and their succulent growth, which suffers quickly if allowed to become dry. There are few plants of easier growth or propagation, the present being a very good time for securing cuttings. Cut flowers in long sprays may be had from this *Eupatorium*, but it is best placed in water as soon as cut, because it soon flags. If it is gathered for packing it should be deeply immersed in water as soon as removed from the plants, otherwise it soon becomes withered and useless. It may be said against it that at Easter there are a wealth of other spring flowers; but even if this be true, to those who have the convenience there is room for this plant.—W. S.

The Reign of the Daffodil.

New Daffodils.

FEW flowers of the garden have gained such an immense share of public esteem during the past few years as have the Narcissi and Daffodils. In practically every garden throughout the length and

FIG. 103.—NARCISSUS DOROTHY KINGSMILL.

breadth of the land they are to be found in varying numbers, and with this increase in popularity there have happily been decided improvement in their cultivation. It is not, of course, in every garden that one finds the newest and rarest varieties; there are growers who have no desire to be right in the van in this respect, while others have not a sufficiently elastic purse to find the means to purchase exceptionally expensive bulbs. Nevertheless the newer varieties do find their way over a wide area in a very brief space of time, and instead of the popularity of Daffodils being, as some of the pessimists say, on the down grade, it is constantly increasing, as well among the masses as among the classes.

There are, however, and always will be people who must have novelties—new varieties are eagerly sought, and to meet the demand many expert growers are at work. Foremost amongst present-day raisers stands the Rev. G. H. Engleheart, who has done really remarkable service in giving to the world new and improved forms. Each year brings with it introductions from the Andover garden, and the labours in crossing in past years are now bearing abundant fruit. From time to time numbers of Mr. Engleheart's seedlings have been portrayed in the *Journal of Horticulture*, and it will be remembered that these varieties are always characterised by clearness of colour and refinement of shape. At the meeting of the Royal Horticultural Society on April 24th, Diana, Chancellor, and Virgil were all honoured by awards of merit from the Narcissus Committee. Each of these was most excellent, the last named being undoubtedly one of the finest varieties of poeticus that has ever been exhibited. At the previous meeting, too, N. Alma was similarly honoured. Thus Mr. Engleheart annexed four awards at two meetings

in an unfavourable season, and has often done better than this in by-gone years.

Miss Willmott of Great Warley was in great form with Daffodils on this occasion, and received special recognition for four varieties out of a small collection. These were named respectively Charles Wolley Dod, Eleanor Berkeley, Countess Grey, and Mrs. Berkeley. The first two received awards of merit, and the last two first-class certificates. Probably general opinion would decide that Countess Grey was the best. It belongs to the bicolor section, and has a sulphur yellow trumpet of perfect form. Both C. Wolley Dod and Eleanor Berkeley favour the popular Sir Watkin in form, differing from that variety and each other in colour. Another exhibitor of a few varieties was Mr. A. Kingsmill, who received a first-class certificate for Dorothy Kingsmill, which was beyond doubt one of the finest flowers in the hall. It is a large bicolor, faultless in form, and of exquisite colour. The perianth segments are pure white, and the beautiful trumpet is sulphur yellow. This variety is admirably depicted in the illustration (fig. 103).

A fresh exhibitor at the Drill Hall is the firm of M. Van Waveren & Sons of Hillegom, the great Dutch bulb growers. On the occasion of the last meeting the firm sent a small collection, amongst which was found a variety named Van Waveren's Giant (fig. 104), which may safely be regarded as the colossus of the family up to now. It is a noble flower, though some people will probably think it too large. It is upwards of 5 inches across, the perianth segments and the trumpet being of proportionate size. The colour of the segments is pale yellow, while the trumpet is rich yellow. It will probably be some time before this variety is exceeded in size. It was recommended a first-class certificate by the committee of experts. The same firm also sent Olympia, which was a grand variety. Another Dutch house, Messrs J. de Groot & Son, exhibited Wilhelmina, which is a bicolor of considerable size and substance, and is of a good colour.

It will thus be seen that eleven distinct varieties were honoured at one meeting, which fact alone goes far to prove the widespread popularity of this delightful flower. The season has been most unfavourable for the proper development of the blooms, or it is probable that many others of equal merit would have been shown. There were, of course, many other new varieties shown, some of which were excellent, but the Narcissus Committee fixed a very high standard on this occasion to which these might not quite attain, though a few years back they would have been recognised without hesitation. There will probably be a further supply at the meeting on May 8th.

Daffodils in Pots.

FINE showy varieties of these "gay flowers of spring" are now so numerous that a good collection should be in every garden, for although the old and well known forms are attractive and useful for supplying cut flowers, they cannot vie in quaintness of beauty with many of the grand, modern varieties, which have become almost as much the rage as Tulips were in their "palmiest days."

To secure a good stock of a few dozen of the best varieties in commerce would necessitate a larger expenditure than the majority of gardeners could devote to the purpose, but many could make a point of procuring a few each year, grow them in pots, and after drying the bulbs plant them out in early autumn. In a suitable soil they would then in a few years have a largely increased stock. Such choice varieties should of course not be forced, but brought on gradually in cool structures, so as to have them in flower during March and April.

To grow Daffodils in pots well a light, rich, perfectly sweet soil is necessary, and to have it in the right condition it should be stacked from nine to twelve months before being used. Procure fresh, rather light loam, with plenty of fibre, and place in a heap; form this with 18-inch layers of soil and 6-inch layers of short, partially decayed manure sandwiched between, then by the time the soil is chopped down for use the fibre has to a great extent decayed and the manure

sufficiently decomposed to render it inviting for the roots of bulbous plants, which always avoid crude manure. Soil thus prepared only needs a fourth of leaf soil and some sharp sand added to make it thoroughly suitable for Daffodil growing.

When potting the bulbs in autumn, drain the pots well and use those 6 or 7 inches in diameter for the majority, but if a few large potfuls are required for special purposes, 8-inch ones may be safely used. I like the crown of the bulb to stand just above the soil. After potting plunge the pots in cocoa-nut fibre refuse, weighted with ashes to keep the bulbs from being forced upwards by the roots. When the young growth is 2 inches in length remove the pots to a cool pit, darken for a time, then gradually expose to full light, and abundance of air when the weather is favourable. If it is desirable to make a special display of Daffodils in the greenhouse during April, leave them in pots till the flower buds are visible, but of course the plants should be given plenty of room to insure sturdy growth, and a little weak soot water given occasionally will help to secure deep green foliage.

When the plants are removed to a greenhouse they ought if possible to be kept within a foot of the glass, and the floors and stages should be damped during bright weather. When the flowers are opening shade for a few hours daily during bright weather, and support large leaves and flowers by placing stakes round the sides of the pots, connecting them with bands of raffia. Treated in this way they look more natural than when each flower is staked separately.

Now for a few words in regard to varieties, which in reality need seeing to be fully appreciated, yet we trust a few descriptive notes will help intending purchasers in their efforts at selection. During the last few years many new varieties—quite distinct in colour and form from older ones—have been exhibited, and ere long the best among them will find their way into the collections of all connoisseurs. Apricot is one which I think has come to stay, as it is a striking flower, having a white perianth and long straight trumpet, yellow deepening to buff-apricot, and in addition is delicately perfumed. Fred Moore has a giant deep golden trumpet and primrose perianth, and is altogether a flower of great substance. Grace Darling, with its white perianth and soft primrose trumpet, has a charm and grace of its own, and being a strong and sturdy grower cannot fail to please. Proserpine is a flower in which white and yellow shades of colour are combined in a charming manner. Shakespeare seems quite worthy of so great a name, as it stands out clearly as a giant among pigmies; the perianth is sulphur-yellow, and the trumpet broad, large, and of a deep golden yellow colour.

Bulbocodium citrinum, one of the pretty Hoop Petticoat Daffodils, is quite worthy of being grown in pots, as the broad bell-shaped trumpets and narrow twisted perianths, of sulphur colour, combine to make it a refined and striking flower. Mrs. Walter T. Ware is a grand grower, having broad thick leaves and bold flower. Sir Watkin, John Nelson, Henry Irving, Backhousei, Barri conspicuus, bicolor Ada Brooke, b. Empress, b. grandis, Burbidgei, Golden Spur, Emperor, Beauty, King of the Netherlands, Mrs. Langtry, and Shirley Hibberd are all fine representations of the various sections of the genus Daffodil. Let us all strive to grow them well, so that in the days to come our gardens may be rendered gay with their gorgeous flowers during the changing yet hopeful days of spring.—NARCISSUS.

Daffodils at Ditton.

THE Londoner who misses the Daffodil feast at Long Ditton loses one of the greatest treats that are provided for metropolitan horticulturists. There one may find in Messrs. Barr & Sons' unexcelled collection all the most popular varieties by the thousand, and all the newer varieties that have been placed in commerce. The effect

produced by the hundreds of thousands of flowers is literally remarkable, and it is curious to note how some varieties eclipse others in the mass when seen from a distance. Regular visitors go to Barr's, and probably would as soon think of losing their dinners as of missing that short journey to Surbiton. Not that all those who make the pilgrimage are Londoners; by no means. There are experts and others who travel scores and even hundreds of miles yearly for the sole purpose of going through the newer sorts in the collection, and thereby gleaning valuable information respecting them that could with difficulty be obtained elsewhere.

From this aspect of the case the great value of the collection lies in the facilities it affords for precise comparison. There are grown practically side by side, in the same soil and aspect, under precisely similar methods of culture, old and new sorts, and it is under such circumstances that certain results can be insured. A new variety that has been judiciously boomed is there in contiguity to an older one of similar type, and the observer is not slow to seize upon the merits and demerits of both and decide which, from his point of view, is the better of the two. Happily for the producers everyone does not think alike, and thus it results that what one likes another dislikes, and of course *vice versa*. If this was not the case one may naturally suppose that both the bulb growers and the bulb merchants would have just cause for lament. True there are a certain number of varieties that appeal

FIG. 104.—NARCISSUS VAN WAVEREN'S GIANT.

forcibly to the fancy of everyone, but these, comparatively speaking, are few, and at Ditton everyone will find abundance of material from which to make a choice.

This season cannot be described as a favourable one for Narcissus, and were I judging from my own collection I should write it down as a thoroughly bad one. This is not because we have had much inferior flowers, but simply from the fact that the vast majority were in full bloom at the same time, thus curtailing the length of the display to a serious extent. Of course this is not so noticeable in a vast collection such as that at Long Ditton as it is in the smaller, and as a result less varied one, but no doubt even large growers have felt the effects

more or less. The protracted cold and wet weather kept the buds in practically one condition for a considerable time. Then came a few days of unseasonably hot weather, and varieties that had previously been unnaturally late burst their buds, as it were, by magic, and they were gone. We had hundreds of flowers for about four days, but afterwards there was almost a famine in the land, and it was only with difficulty that a dozen really creditable specimens could be found within eight days of the time of plenty. I am hoping for better things next season, and in the meantime had better return immediately to Barr's.

As an individual, no single person has done more (probably not nearly as much) than Mr. Peter Barr in the popularisation of the Daffodil. To his strenuous efforts, continued over a long series of years, we owe their abundance and their presence in thousands of gardens. Such being the case, it is only just and right that when his sons name a variety in his honour it should be one head and shoulders above its fellows. Peter Barr is in all probability the finest Daffodil in the Long Ditton Nurseries, or at any rate it was when I recently paid my annual visit. It is a superb white variety of the Magni-coronati section, and of its colour is unquestionably the finest I have seen. A large, bold flower is this, that is not a bit afraid of looking you in the face as if with a knowledge of its superlative excellence. Not very far from Peter is an unnamed seedling of the poeticus section of Messrs. Barr & Sons' own raising, which for purity of colour, excellence of form, and for substance is unsurpassed. Big Ben ought with such a name to be of the first quality, and so it is. The bright yellow trumpet is exceptionally large, and the paler perianth segments are of splendid shape. These form a trio of new varieties that will probably be heard something about ere many more years have passed away—at any rate, it will not be Messrs. Barr's fault if this is not so.

Notwithstanding such peers amongst flowers as those just named, we have always with us the older sorts—indeed we should be quite at a loss without them. Who would be without a clump of Emperor whose handsome flowers are perennially admired, or Ard Righ (fig. 105, page 375). Then look at the sister flower Empress, with its white perianth segments and its large but refined trumpet; can it be spared? The noble Sir Watkin (fig. 105) never loses one atom of popularity; on the contrary it seems to become a greater favourite every year. It is one that thrives magnificently within the smoky areas of towns, though of course under such conditions the colours are not so clear and bright as when grown in a healthier atmosphere. Duchess of Westminster, under similar circumstances, is one of the best, and at Long Ditton both sorts are superb. The bicolors Horsefieldi and the later flowering grandis need no praise here, for they have made their own reputations by continued excellence over many years. Barri conspicuus is old in years but young in health and vigour, and is grown by the hundred thousand, and yet one is informed that more could be disposed of.

One of the best known varieties of the incomparabilis section is Stella, but it must now go to the wall before the newer Stella superba, which is indeed truly named. It produces its strikingly handsome flowers on stout footstalks well above the foliage, and it must be regarded as one of the varieties of the future. The rich colour of the crown of Gloria Mundi makes it a universal favourite, though, unfortunately, it is not everyone who can have a really good stock of it. The Leedsis, the Burbidgeis, the white trumpet varieties, and many others all ought to have detailed attention, but such a course would involve an immense amount of time, as well as occupying an enormous amount of space, so they must be passed over, for this year at any rate.

Irises and Narcissi seem a natural association, hence I presume the inclusion of Iris reticulata (fig. 105) in the illustration before me as I write. Black and white, however, fail to do justice to this singularly attractive and deliciously fragrant flower, which cannot but adorn every garden where it is grown. It is a favourite with everybody alike, and, when exhibited in good condition at the spring shows by first-class growers, receives general approbation. Messrs. Barr & Sons grow many Irises with signal success, just as they do Narcissi and Daffodils, with hundreds of other kinds of flowers, hence it is that one can never make a mistake in proceeding to Ditton, for there is always something in flower to be admired and to instruct. Late Tulips will, as is customary, be the *pièce de résistance* during the present month. This, at any rate, is the view held by—AN ANNUAL VISITOR.

The Habrothamnus.

THIS well known greenhouse evergreen flowering shrub is admirably adapted for covering the back wall of a conservatory or greenhouse. It may be planted in a border or grown in a large box, tub, or pot. To plant it out and allow free root room is probably the better method of culture, especially if ample space can be found upon which to train the growths. A strong and vigorous plant will grow easily to the height of 10 feet if planted out. In a pot the growth cannot be so vigorous, yet it is possible for good shoots to be made and to become well ripened, which is an essential to free flowering. In unrestricted root space the growth being so strong is liable to fail in becoming thoroughly well ripened, hence it is desirable while encouraging freedom of growth to also apply some restrictive check by confining the rooting to a given, but ample space.

The Habrothamnus is propagated by cuttings, selecting these as short young side growths starting from the old wood in spring. They are best taken off when 4 inches long, being then short, vigorous, stubby shoots. When they are taken a portion of the old stem should be attached at the base. A plant may be induced to form this type of cutting by pruning the stems, and placing the plant in heat, keeping the soil just moist, and syringing daily. Growth will soon push, and may be taken when they have reached the length stated. The cuttings should be inserted round the edges of 3-inch pots, two or three in each pot. Employ sandy soil and surface the compost with sand. In a moist temperature of 65° the cuttings soon form roots. In a greenhouse temperature it would be best to place the cutting pots in a box, pot, or frame, and cover with glass, by this means keeping the cuttings fresh until roots form. The warmth and moisture of a hotbed is likewise a suitable place for them.

When the cuttings have rooted pot them singly, encouraging growth in warmth and moisture. For the first season the plants may be grown to a single stem, or if they are to be grown in a border plant them out as soon as they are well established in the small pots. When intended for pot, box, or tub culture the plants should be systematically repotted. The border ought, of course, to be well drained, and the soil employed consist of loam, leaf soil in equal parts, with a free admixture of sand and a little decomposed manure. Make these materials firm and compact round the ball of roots when planting, so that the new soil is as firm as the old ball. In cases, however, where the plants may have been long in the pots, so that the roots have entwined themselves round and round, some of them must be disentangled and spread out before finally completing. The ball, moreover, should in all cases be moist.

After potting or planting water must be given with care, especially so when the ball is old and very full of roots, as it is possible for this to dry out before the soil surrounding it does so. When once well established there is less difficulty in the supply of water. The plants will need it when the soil on the surface dries. Give sufficient at this juncture, then wait until the same conditions present themselves again.

On becoming well established after planting out freedom of growth will be a characteristic of those in borders, and the main point is to train the growths out well for the purpose of covering the space and to permanently originate some main growths, these being equally disposed over the available training space. Growth of plants in pots after the first season should be cut well back, as it is necessary for strong shoots to be made, which will form a good groundwork or foundation. These ought to be disposed to the best advantage and extended as far as convenient. If it cannot be done in one season it may in succeeding years. From these main growths lateral shoots will extend, which each year after flowering can be shortened closely back. Growth will afterwards break, and the shoots formed during the season will flower freely the next season. This system may be continued each year, and when a main shoot is becoming exhausted another may take its place by training one in from the base. Weak supplies of liquid or artificial manure are beneficial when the plants possess plenty of roots. Assistance of this kind is very helpful just previous to flowering and when good growth is being made.

The Habrothamnus appreciates moisture and warmth when new growth is being produced, but a free circulation of air and abundance of light is necessary to ripen the wood. The flowers appear in winter and early spring, and are borne at the points of shoots. In *H. elegans* they are carmine, in *H. fasciculatus* crimson. Green fly is the greatest pest these plants can have, though they are subject to red spider, but only in a dry atmosphere and when deficient of water at the roots. Green fly is not so troublesome under good culture and free ventilation. —E. D. S.

NOTES & NOTICES

Recent Weather in London.—The difference between Saturday, the 21st, and Saturday, the 28th ult., was remarkable; on the first named it was intensely hot, and on the latter it was decidedly cold with some showers. These were the conditions again on Sunday. Monday was a wet, cold day, with hardly a gleam of sunshine. Tuesday opened milder, and the day continued fine. On Wednesday it was quite summerlike.

Weather in the North.—For the week ending the 30th ult. the weather was decidedly colder, and dense hoar frost occurred on the 27th and the 28th, 6° and 10° of frost being reported from a central county on these mornings. The wind up to Monday evening continued in the N.W., and was very cold. Snow still lingers even on the southern slopes of the hills.—B. D., *S. Perthshire*.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, May 8th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Is there any Natural Limit to the Improvement of Cultivated Plants?" will be given by Mr. W. Bateson, M.A., F.R.S., at three o'clock. A schedule of the Temple Flower Show can now be obtained on application to the Sec. R.H.S., 117, Victoria Street, S.W., enclosing a stamp.

New Gardens for the Royal Horticultural Society.—For the purpose of giving full effect to the decision of the general meeting of the society, held on April 25th, requesting the council to examine further sites for the new gardens of the society, the council request any Fellow who knows of a suitable position to be so kind as to send at once to the office of the society detailed particulars of the acreage, distance from London, nearest railway station, aspect, nature of soil, name of owner or agent, and price.—W. WILKS, *Secretary*.

Thompson's "Gardeners' Assistant."—This standard work on horticulture has been thoroughly revised and enlarged by numerous specialists under the general editorship of Mr. W. Watson, and will, we are informed, be ready for issue early in May. The new edition will be in the form of two volumes, each of about 600 pages, and fully illustrated by coloured plates and engravings.

The Alexandra Palace.—We learn that the Middlesex County Council at a recent meeting adopted a recommendation of the General Purposes Committee to contribute £49,000 towards the purchase of the Alexandra Palace and park of 172 acres, subject to the enfranchisement of the 28 acres of leasehold. This splendid space is thus likely to become the property of the people of North London at no very distant date.

An Important Sale of Books.—The valuable library of botanical books brought together by the late J. T. Barber, Esq., Aston-on-Clun, was sold last week by Messrs. Sotheby, Wilkinson & Hodge. Some of the most important included Mr. C. Cooke's "Illustrations of British Fungi," 1881-91, £21; Curtis's "Botanical Magazine," from the commencement in 1787 to 1879, complete set, £91; Edwards' "Botanical Register," 1815-47, complete set, £44; James Sowerby's "English Botany," 1790-1849, in forty volumes, £36; H. Andrews' "Botanists' Repository," 1797-1815, ten volumes, £10 5s.; C. Loddiges' "Botanical Cabinet," 1817-33, twenty volumes, £38; De Martius' "Nova Genera et Species Plantarum Brasiliensium," 1824-32, £15 10s.; Reichenbach's "Iconographia Botanica seu Plantæ Criticæ," 1823, &c., £18 10s.; Reichenbach's "Icones Floræ Germanicæ et Helveticæ," 1834-62, twenty volumes, £40; J. Bateman's "Orchidaceæ of Mexico and Guatemala, 1843, £11; H. J. Elwes' "Monograph of the Genus Liliium," 1877-80, £10; R. J. Jacquin's "Hortus Botanicus Vindobonensis," 1770-76, £22 10s.; "Plantorum Rariorum Horti Cæsarei Schœnbrunnensis," 1797-1804, £31; "Stapeliarum in Hortis Vindobonensibus, 1806, £14 5s.; "Fragmenta Botanica," 1809, £10; John Parkinson's "Paradisi in Sole," 1629, perfect copy, £22 10s.; Giovanni B. Pirane's works, in twenty-one volumes, £54; P. J. Redouté's "Les Liliacées," 1807, on large paper, rare, £50; Ruiz et Pavon's "Flora Peruviana et Chilensis," 1794-1802, £25 10s.; and F. Sander's "Reichenbachia," 1888-98, £29.

The Gardeners' Royal Benevolent Institution.—The sixty-first anniversary festival of this institution will take place on Friday, May 18th, at the Hôtel Métropole, when the Duke of Portland will preside. His Grace will be supported by the Dean of Rochester, Viscount Powerscourt, the Right Hon. A. H. Smith Barry, M.P., and other influential gentlemen.

Gardening Appointment.—Mr. C. B. Elliott, for the past seven years head gardener to the late Mrs. Wilsons, Luneville, Torquay, has been appointed head gardener to Major Willie, Blythe Hall, Blythe Notts. The place became vacant through the sad death of Mr. Walter Elliott, who passed away on the 5th of April, after a very short illness, at the early age of thirty. There were over 100 applications for the post.

The James Martin Memorial Fund.—We are informed that the committee of the Martin Memorial Fund has decided that the fund shall be closed on Saturday, May 12th. The amount already raised is £133 7s., which includes the £50 with which Messrs. Sutton and Sons headed the subscription list. Those who are desirous of contributing to the memorial to the late expert hybridist should forward the amount forthwith to the honorary secretary, Mr. H. G. Cox, Ferulea, Junction Road, Reading.

Vandalism at Richmond.—The beautifully wooded cottage ground in the Old Deer Park, Richmond, presented by the Queen to the nation, is to shortly have a large physical laboratory at its side, in spite of the announcement previously made by Mr. Akers-Douglas in the House of Commons, that this most beautiful bit of wild country in the proximity of London should not be cut up unnecessarily. The proposed desecration, moreover, would be against the wishes of her Majesty, the donor, who expressed herself as follows:—"The Queen most earnestly trusts that this unique spot may be preserved in its present beautiful and natural condition." It is to be hoped that the destruction of this beautiful woodland sanctuary will be averted.

The Gladstone Conservatory, Liverpool.—The name of Henry Yates Thompson, Esq., will ever live in the hearts of Liverpool citizens on account of his magnificent gifts to the city, and more especially of the grand Palm house in Sefton Park, and lastly, the splendid Palm house which was opened in Stanley Park, a densely populated part of the city, on St. George's Day. Alderman Joseph Ball, the chairman of the Parks and Gardens Committee, was deputed to open the building, which is a model of the temperate house at Kew, and is surrounded by lawns in capital condition, the necessary band stand being near to the main entrance. The conservatory is 120 feet long, 50 feet wide, 10 feet high at the eaves, and 30 feet to the ridge, and with exception of teak ventilators, is composed of iron. A verandah 8 feet wide and 15 feet high, with suitable seats, will be found of great advantage when the bands are engaged. Standing near to the doorway is a capital bust of Mr. Gladstone, and underneath is a passage from a speech in which he stated, "I myself have seen the wild Roses blowing on the very ground which is now the centre of the borough of Liverpool." It must be admitted by all that the conservatory is one more instance of the excellence of the work of Messrs. Mackenzie & Moncur. The value of the excellent gift is upwards of £8000.

Isle of Wight.—On April 4th Mr. F. D. Hills gave an interesting lecture before the members of the Cowes Horticultural Improvement Society on "Bees and their Value to Gardeners." On April 7th Mr. T. S. Rooper gave an instructive lecture under the auspices of the I.W. Horticultural Improvement Association at the Guildhall, Newport, on "The Value of Gardening as a Means of Education." Dr. J. Groves, B.A., J.P., presided. On the 18th and 19th the Ryde Horticultural Society held a two days' show of Daffodils and spring flowers in the Town Hall. The local exhibits were not all that could be desired, but the exhibit of Messrs. Barr & Sons gave every satisfaction and received much praise. Messrs. Barr & Sons have done a great deal to develop the cultivation of spring flowers in the Garden Isle by their annual visits to the spring shows. On the 18th the Shanklin Horticultural Society held its first exhibition of Daffodils and spring flowers in the Institute; it was an innovation which caught on, and is calculated to do much good in this popular island resort. Messrs. Barr & Sons had an excellent exhibit. On the 21st Mr. J. S. Walker read a paper on the "Vin," under the auspices of the I.W. Horticultural Improvement Association, which was thoroughly practical and was much appreciated.—S. H.

Death of Mrs. George Abbey.—We learn with deep regret of the death on April 27th of the wife of Mr. George Abbey, who must be numbered amongst the oldest contributors to the *Journal of Horticulture*. Many readers will unite with us in tendering sincere sympathy to Mr. Abbey in his bereavement. The funeral takes place to-day (Thursday) at St. Alban's cemetery.

Nottinghamshire Horticultural Society.—The schedule of the exhibition of the Nottinghamshire Horticultural and Botanical Society, which is fixed for Wednesday and Thursday, June 6th and 7th, has reached us from the honorary secretary, Mr. C. J. Mee, 29, Long Row, Nottingham. It embodies about fifty classes for flowers, plants, fruits, and vegetables, in several of which really generous prizes are offered. One of the chief classes is that for a 200 feet group of miscellaneous plants, with a first prize of £15 and a 10-guinea silver cup, and other awards of £15, £10, and £5 respectively. This should bring forth some handsome exhibits. All necessary information as well as schedules will be provided by the Secretary at the address given above.

Irish Gardeners' Association.—On Thursday evening, April 26th, the Gardeners' Association of Ireland held its usual meeting at D'Olier Street, Dublin, Mr. O'Kelly in the chair. The attendance of members was sparse. After the usual routine business had been transacted Mr. J. Shaw contributed a highly instructive paper on "The Daffodil," covering the historical part and the labours of our modern hybridists. He laid special stress on the work of Mr. Leeds of Manchester. In covering the ground for classification he quoted several extracts to reveal how Parkinson had first started it, and how we had had to wait until Mr. Baker of Kew undertook the task. In conclusion Mr. Shaw dwelt on the most suitable sites to grow Daffodils; he preferred the moist banks of the river, where the nodding blooms contrast well with the limpid waters below; also in grass and woods. When dealing with the culture, he preferred to top-dress the beds with leaf mould, and, whilst the soil should be rich, his experience would lead him to say that heavy manuring is highly deleterious to the Daffodil.

Chester Paxton Society.—In conjunction with the botanical section of the Chester Society of Natural Science, Literature, and Art, the Paxton Society got together last Thursday an excellent exhibition of spring flowers. One of the large rooms in the Grosvenor Museum was given up for this, and the attendance far exceeded that of any previous year. The largest collection was that from Eaton Gardens, per Mr. N. F. Barnes, who staged excellent examples of culture. Dr. Mules, of the Old Parsonage, Gresford, sent an interesting and valuable collection. Exceedingly effective was a vase containing a dozen blooms of *Narcissus Madame de Graaff*. Close by in another vase was the same number of blooms of *N. Virgin Mary*, the whole stock of which, we believe, is in the hands of the doctor. This is a variety quite worthy of extensive cultivation, and doubtless more will be heard of it in time to come. Miss Humberston, Newton Hall, per Mr. R. Wakefield, also sent an interesting collection of well grown plants and flowers. Other exhibitors included Mr. John Wynne, Waverton; Mr. J. Gibson, Glan Aber Park; and Messrs. Dickson, Ltd., whose collection of *Narcissus* blooms was much admired. Considering the exhibition was a non-competitive one the society has every reason to be satisfied at its success.

Bristol Gardeners' Society.—The second annual meeting was held at St. John's Parish Room on Thursday, 26th ult. Mr. G. Brook presided over a large attendance. The report presented showed that the society is progressing, the present total membership being 127, with an average attendance of about sixty. The financial statement also proved successful, the balance in hand, after all expenses were paid, being £5 2s. 3d. A letter of apology for non-attendance was read from the president, H. Cary Batten, Esq., who consented to continue in that office. The other officers elected were:—Chairman, Mr. G. Brook; vice-chairmen, Messrs. Hancock and Binfield; hon. sec. and treasurer, Mr. W. Ellis Groves; assistant secretary, Mr. W. Haddon; and a committee of fifteen members. During the evening Mr. W. Ellis Groves, the hon. sec. and treasurer, was presented with a handsome barometer. Mr. G. Brook made the presentation on behalf of the members, and in a brief speech spoke of the untiring energy which Mr. Groves had displayed for the benefit of the society and the able way in which he had carried out the duties connected with the position, and expressed a hope that he would continue to act for them. Prizes for foliage plants were secured by Messrs. Shaddick, McCulloch, and Sutton, and a prize for two flowering plants by Mr. Shaddick.

Beckenham Horticultural Society.—Mr. A. Dean delivered an address on "Edible Stem Plants" before the members of the above society at the Beckenham Public Hall, on Friday, April 27th. Introducing his subject, Mr. Dean alluded to the fact that the majority of young men despised work in the kitchen garden, considering it to be of a menial character. The great desire was to get in the houses, entirely neglecting what older and more experienced gardeners found to be all-important—viz., the cultivation of vegetables in sufficient quantity and of the best quality. Asparagus, Seakale, and Rhubarb were considered to be the most important of the edible stem plants, on account of the long season each might be had in good condition—where the soil was suitable—and some valuable hints were given on their culture. A hearty vote of thanks was accorded the lecturer.—M. W.

Birmingham Gardeners' Association.—At a recent meeting of this society, Mr. W. B. Latham in the chair, Mr. William Spinks read an interesting and instructive paper entitled "The Aquatic Garden." A select list of some of the best and hardiest hybrid Water Lilies was given, as well as of other suitable water and waterside plants. In the ensuing discussion Mr. W. Gardiner alluded to the essayist's successful arrangement and the planting of the superb rock and water garden at The Uplands, Sellyhill, near Birmingham, and of which illustrations were so admirably shown in the *Journal of Horticulture*, July 20th, August 24th, and September 21st last year. The meeting was further enhanced by several exhibits, including examples of hybrid *Cinerarias* and *Coeogyne Sanderiana*. A certificate of merit was awarded to a finely flowered specimen of *Dendrobium Brymerianum* of superior form, and Mr. W. Gardiner exhibited specimens of well-kept English, Tasmanian, Canadian, and Californian Apples illustrative of varieties from various quarters of the world.

Frost and the Jersey Potato Crop.—It is reported that owing to hard frost on Saturday night the Jersey new Potato crop has suffered severely. Hundreds of acres which on Saturday were looking remarkably well have been blackened. It is not possible to estimate the loss, but it means ruin to many farmers. Much damage has also been done to the early crops in East Kent by the extremely cold weather following the recent few summer-like days. Nevertheless the fruit prospects are more promising than for several years. Where early Potatoes are up, the haulm has been destroyed by the night frosts.

Frost Injuries in Bedfordshire.—On Thursday last, April 26th, a disastrous frost was registered here, the thermometer on the ground recording 18° 8' Fahr., or over 13° of frost. The result is severe injury to flowers and plants. Plums and Damsons have a most abundant display of blossom this season, and all the flowers expanded at the time were destroyed. Some of the later varieties and trees still, however, afford the prospect of a crop. Early flowering Pears are also severely cut, Gooseberries have suffered slightly, Red Currants considerably, and in some places the early Strawberries have their leaves and flowers blackened, though the latter are still in the bud stage. Quantities of Asparagus have been cut down, early Rhubarb is somewhat damaged, and Cabbages have all their fully developed leaves browned. In one low-lying district acres of Cabbages have been greatly injured, while seedling vegetables like Brussels Sprouts have been generally destroyed.—R. LEWIS CASTLE, *Ridgmont*.

The weather for the past week has been fine but very dull, with cold wind.

The Barr Daffodil Cup.

WHILST generally agreeing with "Daff's" criticism, on page 333, I can only conclude that its tone may lead some to infer that a reflection is cast upon the single exhibit to which the cup was awarded. Probably this was unintentional on his part, but the fact remains that a jarring note has been struck, and one cannot but sympathise with the winner when he says, "There is certainly no honour in winning a prize when there is no other exhibitor, . . ." Under most circumstances I could agree with your correspondent on this point, but in this case it looks a little ungracious to detract from an exhibit of high merit, which obviously could not have been conveyed from Lismore, in the south of Ireland, to London without much trouble and some expense. Whilst the lateness of the season accounted for the absence of competitors, I do not think that it provided much excuse for the non-employment by them of legitimate methods to hasten their blooms in order to compete at a given date with the more naturally favoured ones from the Green Isle. As an old exhibitor of the Daffodil I can say that it is much easier to push forward sufficient blooms to make up a representative stand than it is to retard them in an early season; and that none appeared to think it worth the "struggle," may have been Miss Curry's misfortune, but was certainly not her fault. Under the conditions in which the Barrian cup was won this year there seems no sound reason for the attempt to deprive the lady of her honours, and evidently the judges were of this opinion.—S. H. B.

Garrya elliptica.

IN a recent number of the Journal you gave a capital illustration of the above plant, and in the subjoined text, in speaking of its worth and beauty, you referred to it as being not reliably hardy in the south unless grown as a wall plant. This, I regret to say, is the generally accepted theory with regard to its requirements. As a fact its value in the bush form seems quite unknown, though it is not only quite hardy in many localities, but also quite amenable to cultivation as a bush plant.

Only a few yards from where I write, until quite recently, a pair of very fine plants grew and flourished amazingly. During the past winter the weight of snow, coupled with the increased weight on the branches by the great load of catkins, brought the plants down somewhat, and though still profusely laden, as in all probability they had never been laden before, with catkins, this became an offence in the eyes of the gardener who tends the place some two or three days weekly. The plants were some 10 feet high and through, and were fully thirty years old, as the gardener had known them upwards of twenty-five years, and he found them good plants.

During all these years no knife had been allowed to touch them, the plants being justly treasured by two ladies, one of whom has passed away, the other an invalid. But notwithstanding that the plants were so greatly prized by the owner, the gardener in some way obtained permission to prune them "according to his judgment." Unfortunately this latter was of a far reaching character, and as time was money, a large sized hand saw was requisitioned for the work, and in a few minutes the beauty and growth of thirty years was strewn at his feet, the plants cut down to within 2 feet or so of the ground. Each of the plants had several principal lateral branches proceeding from a main trunk about 9 inches in diameter, several of the leading shoots being about 3 inches diameter.

The plants formed so striking an instance of successful culture that I obtained a leading lateral and showed the same before the Floral Committee at the Drill Hall at the last meeting, my chief desire in so doing being to demonstrate the value of this beautiful shrub, and to extend its cultivation in the bush form. In all those thirty years these plants had not been injured by frost, and the great wealth of catkins as the two plants were gradually closing together made one continuous bank of grace and beauty. The plants occupy a slightly raised and sloping bank, which must be excessively dry in summer. The soil is exceedingly poor, and in all probability has not been manured since the examples were planted. On the opposite side of the road a belt of trees, principally Sycamore, shield them from the north, while they are rather exposed to the east. The wood of the Garrya is very heavy and hard, quite equal to Box or Holly for weight. I believe the exhibited log has been accepted by the Kew authorities as a sample of British-grown Garrya.—E. H. JENKINS, *Hampton Hill*.

The New R.H.S. Gardens.

IN one respect the otherwise almost abortive meeting of the Fellows on the 25th ult. did something practical. It settled unanimously the question as to leaving Chiswick, and getting a new garden. That is something, and at future meetings the president can, and indeed must, put his foot down firmly on any further attempt to cause the Fellows to recur to it. An absolute mandate given on the most ample notice to all the Fellows has now been given to the council to find a site for a new garden, but it must, of course, be one satisfactory to "a majority of the Fellows," although all who know anything of the conduct of general meetings know that resolutions are carried only by majorities, and that consequently Mr. Pearson's addendum to the council's resolution was largely surplusage; still it serves to show, into such a muddle had the business fallen, that the meeting greedily caught at anything to extricate it from its mess, and, therefore, adopted this surplusage gladly. But whilst the resolution pledges the council and the Fellows to find a new garden other than the old one at Chiswick, it does not stipulate for hurry. But every year Chiswick becomes a less satisfactory garden, and every year its lease becomes of less value, hence the sooner the new gardens are found the better.—A FELLOW.

I CANNOT but regard it to be a great misfortune that so large a number of Fellows of the Royal Horticultural Society should have assembled at the Drill Hall on Wednesday last to so little purpose. It was a splendid opportunity to transact business absolutely wasted, and there was too ample evidence that English gentlemen can be as capable of obstruction as can Irish M.P.'s. To them wasting a few hours is of no moment; to business men it is a matter of the greatest importance. Whenever any fresh meeting of the Fellows is held, it is hoped that not the interests of those who want to prevent business, but that the welfare of the busy men will have first consideration.

But if any evidence were needed as to the irreconcilable views held by various Fellows as to the most desirable place for the new Chiswick were wanting, such evidence was amply furnished at the meeting. Everyone wants a garden in his own locality apparently, and so strong was that feeling in one quarter that it was actually suggested that a site could be obtained some 150 miles from London, as though such were possible or practicable. Any more absurd suggestion can hardly be conceived. It is a matter of absolute necessity that because London is the home of the society, and because all its ordinary meetings are held there, that the new gardens must be within reasonable distance of London—certainly not farther than thirty miles, and less if possible. That ready access can be had to such garden is of course important, but under no circumstances is it possible to expect that any ground suitable for such garden can be purchased immediately contiguous to a railway station anywhere within thirty miles of London, as in all such cases land close by is bought up for building purposes, and it would be folly even were ground obtainable to plump down a garden just where in a few years it would be built all round. Under no circumstances, therefore, can ground close to any railway station be had.

It was a matter for profound regret that a document, without doubt an important one, because emanating from an authoritative source, should have been so freely referred to at the meeting, because that document was at once strictly confidential, and had not been published to the Fellows. It was also specially bad taste to mention the name of an absent yet most able and influential member of the council, who is abroad, as though that absence meant disapproval of the action of the council. That very member some months since at the Drill Hall asked me, as they must get a new garden somewhere, to acquaint the council did I hear of any suitable land in Surrey or elsewhere. To assume that Mr. Harry J. Veitch was antagonistic to the council's proposals was most unjustifiable. It was deplorable that Fellows should still persist in trotting out the proposals for the providing of an exhibition hall in London. That hall at least it seems may be in London, and not in Gloucestershire.

What was the use of flogging so dead a horse as that? It would take more money to purchase a site for a large hall in a central part of London than it would cost to purchase the Limpsfield land as proposed. It was unfair on the part of Sir Michael Foster, M.P., to decry the present hall as being too dark. It may be dark six out of the twenty-four times occupied in the year with meetings, but what hall in London would not be dark on some of these black smoky days, so plentiful in winter? Where, too, could be found a hall that could have so admirably housed the splendid show held on the 24th, or the many hundreds of visitors, as did the Drill Hall? Why do not people think of these things and talk common sense, rather than be crying after the unattainable?

The resolution passed at the recent meeting although it does not shut out of sight the getting of an exhibition hall somewhere, does emphatically do so, as the method of celebrating the society's centenary. It further makes it to be even more imperative than before, on the council to find a site for the new Chiswick. Whether considering all that the council has done in endeavouring to secure sites already, it can find more that shall be acceptable to a majority of the Fellows is very doubtful, and remembering the rough treatment the suggested Limpsfield site so far has had, certainly the council has

little encouragement to do much more than it has. But it is determined a new garden is to be provided, and when an adjourned meeting is called the nature, cost, position, and probable suitability of the selected or other site, alone can be discussed. It is hoped that at any future meeting the bye-laws and the new garden site will be kept quite separate.

The tail of the resolution passed at the meeting signifies that the "majority of the Fellows" must be the majority voting at some special general meeting of the Fellows called for the special purpose of dealing with the council's report on the matter. That such vote will be determined by the nature, extent, and lucidity of the report furnished, there can be no doubt. I think the council would act very wisely in printing such report, with a small map of the proposed ground, and circulate it amongst all those Fellows asking for a copy. That would facilitate matters immensely.

It is very surprising to me that any person should still cling to poor old effete Chiswick as constituting a suitable garden for the society. I have known it intimately for thirty years, and have always felt it was a wretchedly poor place to pose as the leading horticultural garden of the kingdom. Kew is of course splendid. It is a grand garden, but its existence close by only serves to make poor Chiswick look all the more poor and inferior by contrast. It has hardly a glass house that a gardener would care to have; and its huge vinery, noble an erection as it is, only serves to make men marvel why it should ever have been built.

As an example of a vinery it is deplorable. Although both Mr. Barron and Mr. Wright have done all that man could do to make the garden a success, the place is cursed by its surroundings, or, as the scientists say, by its environments. When admirable market gardens are quoted as existing closely, what amazing ignorance is shown! All surrounding market gardens have been or are being built over rapidly, and just as pure air is being excluded from the district smoke, soot, and fog are accumulating yearly. The soil may not be exhausted, but it has become too intensely porous to have in it any retentive properties. Thus things in all parts of the garden suffer at once from excessive soil dryness and superheated atmosphere, because the garden is so boxed in by buildings. Fogs are always worse in the south-west of London than anywhere else, and when they kill autumn sown Onions wholesale at Chiswick what more need be said? Every sensible man knows that for all practical purposes Chiswick is played out. It will be specially imperative on the part of the council in selecting a new garden site to have it quite outside the metropolitan obnoxious smoke and fog area.—A. D.

Gardening in the Green Isle.

MANY, too many, on the Sassenach side of St. George's Channel seem to have some vague idea that the fauna and flora of the Sister Isle are chiefly represented by "the gentleman who pays the rent" and that noble tuber the Potato. The tendencies of late years should go far to dispel these hazy notions. As regards the first, to anyone seeking good specimens of the porcine species I would rather recommend Berkshire. No longer can we regard Erin as the happy grunting grounds, for you may traverse miles, of County Dublin at least, without meeting a single "gentleman." But the Potato? Well, that is another illusion; for even in this department, at the Potato Tercentenary held in Dublin in 1896, Berkshire too bore the palm, the great Reading firm surpassing all exhibits for quantity and quality staged in the round room of the Rotunda. Messrs. Sutton's display was the best they had ever made, weighing over 2 tons, and all so cunningly contrived as to show off the best points. It was the apotheosis of the Potato, but, alas! not Irish. Still the fact remains that in the economy of Irish life the Potato plays an all too prominent part.

The Tercentenary aforesaid was at one and the same time a bright success and a dismal failure. Arranged and carried out by the Irish Gardeners' Association, with the hearty co-operation of gardeners, growers, and scientists, with representative collections from England, Scotland, France, and America to compare with those of the Emerald Isle; and being, too, the right thing in the right place, what more was wanting? Here were the Potatoes, where were the people? Here was his Excellency, Lord Cadogan, standing shoulder to shoulder with a few Irish gardeners, re-counting in his happiest vein the failures of his chef to place a decently cooked Potato upon his table. Here were lectures, limelight views, scientific discussions, practical expositions; in short, all that could be said, shown, or done in the matter, yet the Tercentenary came and went practically unnoticed and unknown. The highest praise could not but be bestowed upon the little band of workers whose labours of love must have been of the highest educational value had they been availed of by the public.

That the finest peasantry in the world still depend upon a Potato patch for their staple food goes without saying, and in that mistaken dependence is to be found, one thinks, an explanation of the poverty of

cottage gardening in Ireland. Cottage gardening as practised in the humble homes of England is virtually unknown, and one can only conclude that were it otherwise its refining influence and economic value would prove potent factors for good in the welfare of the people. There are, however, things which come not within the scope of this paper. Thackeray's semi-satirical criticism of Ireland, as he saw it, might still apply if derived from the same superficial observation. But he saw, as too many see now, only the surface of things. "Still waters run deep," and by long and patient observation only are the undercurrents of life revealed. Then ensues an explanation of things which cannot be explained away, and brings a clearer understanding to many who cannot understand the Irish, and, unfortunately, never will. Be it our endeavour here, however, to deal with things as they are, and not as they seem, in turning over brighter pages in the gardening history of the Green Isle. It contains many beautiful pictures, and gardeners in the fuller sense of the term are not rarities.

Within touch of the Milesian metropolis is more than one stately home embowered in its tall ancestral trees, and numerous pleasing examples of lesser degree adorn the environs of "the car-drivingest city." Overlooking Dublin Bay, among vistas of surpassing beauty, the love of gardening appears to have long since taken deep root, although there are not a few places showing by what remains that its glory has departed. Some of these Irish homes of gardening must have been among the first to avail themselves of Paxton's marvellous creations of iron and glass, and commodious curvilinear plant houses are frequently to be found which point to a period when the gentle art was in an exceedingly flourishing condition. One is often surprised, too, by the large extent of walled-in gardens, the building of the walls of which would alone be a serious matter to contemplate. For instance, at Carton, Maynooth, the original kitchen garden as formed by James, first Duke of Leinster, enclosed twenty-six acres with boundary and dividing walls, and this when reduced by Augustus Frederick, the third duke, to ten acres, as it now exists, forms no mean appanage to a noble demesne. Generations of gardeners have come and gone since the old-fashioned wall nails, still bristling in the ancient boundary wall, secured those well-trained trees in which our forefathers delighted. All this points to a glorious past in Irish gardening, and one ventures to include a passing thought of those past masters of the craft. In the ancient graveyard of Grangewilliam, immediately outside of the Carton demesne, may be seen a huge recumbent limestone slab toned down by age and Lichens. The deeply graved inscription enables the curious to decipher without difficulty that it marks the last resting place of Patrick Allen, sometime gardener to the nineteenth Earl of Kildare, and James (aforementioned) the twentieth Earl and first Duke of Leinster. He it was who ruled over the twenty-six acres of kitchen garden with all the auxiliary horticultural adjuncts then befitting a nobleman of rank; and, rightly or wrongly, one infers that Patrick was a son of the soil. The difference in that respect 'twixt then and now being that Scottish and English gardeners are in the ascendant in the matter of situations held by them. Rest on, old warrior of the spade, in thy doubtless well-earned rest, although neither 100-guinea Orchids exercised thy care, nor the joys and griefs of a "Mum" grower came within thy ken!

One is now and again surprised in visiting some retired, unpretentious place to see relics of former grandeur in the garden; hence it may be deduced that horticulture must formerly have held high rank in Ireland. Some time since a great literary gardener wrote saying we (English) hear too little of what is going on in Ireland; and, it may be added, the gardening world of Ireland is still to many a *terra incognita*. Some of these old world places one would fain describe, for there is that about them which "age cannot wither nor custom stale;" and in this severely practical age they are to us—

"Voices of the past, links of a broken chain,
Wings that can bear us back to times
Which cannot come again."

There are, probably, more of these old-fashioned gardens with all their constant, nameless grace to be found in the Green Isle than elsewhere in the kingdom, and the reason is, perhaps, not far to seek. When fickle fashion ordained a modern system the expense of conversion with the new order of keeping was a serious consideration, hence they escaped the innovating hand. Their owners could just afford to keep them as they were, and no more; but that was all that was necessary, and one feels thankful that it was so. Still, old customs, like old superstitions, die hard in Ireland, and, as relates to the commercial aspect of gardening, this has been and is undoubtedly detrimental. Too many of those who formerly won a fairly comfortable living in eatering for the market appear unable to conform to the march of time, and are dragged along in the procession.

Cut flowers and perishable fruits are scantily supplied to meet the demand which exists; hence in their season, Strawberries from Kent, Narcissus from Scilly, and a host of perishable products are consigned to Dublin, *via* London, when such might by a little enterprise be equally as well grown in favourable localities at home,

Fig. 105.—DAFFODILS AND IRISES. (See page 370.)

and above and beyond that placed on the market in all their pristine freshness. In regarding this commercial aspect as an important question, so far as Ireland is concerned, it may not be out of place to briefly note what is, what has, and what might be done *pro bono Hibernia*. Market gardening on a small scale was for many years a feature on the sunny banks of the Liffey between Dublin and Lucan. This was not the common order of its kind, but that picturesque medley of many things which afforded such a charming *coup d'œil* for over two miles to travellers by "the Lower Road," and both pleasure and profit to the small proprietors. The steep slopes facing due south are a veritable trap for sunbeams, and here were to be seen small plots of early Peas, the earliest of early Potatoes, Strawberries ripening a month before those elsewhere, patches of Pinks and other flowers suitable for cutting, herbs, and marketable stuff galore; snug cabins with thatched roofs, on which trailing Nasturtiums tried to hide the brilliantly whitewashed walls, were dotted ubiquitously about; and doubtless many a stouthearted Irishman now serving his Queen and country in less genial climes oft thinks of auld lang syne and the Strawberry beds amongst which he wandered a sturdy, bare-legged gossoon. That is as it was; now in many a place where once a garden smiled a few ragged goats browse among the ragweed, and ever and anon a roofless cabin lends sadness to the scene.—K., *Dublin*.

Flowering Trees and Shrubs.

THE advance made by vegetation from about the 17th to the 24th of the present month was remarkable for its rapidity, and it is not often that trees are observed to positively leap into life, as has this year been the case. There were few signs of activity at the beginning of the period named, but at the end trees were almost in full leaf, and the hedges were green with bursting buds. Chestnuts are recognised as exceedingly rapid growers, but this season they must almost have established an English record, as they grew several inches in six days. Lombardy Poplars, too, which are not generally so hurried in their movements, came from buds to leaves of the size of a shilling in the same period.

It is, however, useless to attempt to individualise all the examples of rapid growth, as such a task would involve the enumeration of all the plants and trees that grow in our gardens, pleasure grounds, and woods. The varying tints of green are before the dweller in the town as well as in the country, but they are not so appreciable or so delicate in the former as in the latter. The time of the development of the leaf is to many people symbolical of hope, and is to some the period of the year that is most admired. No one can fail to be gladdened by the bursting buds and the developing leaf—promises of the riper beauties of the summer and the autumn. Of these foliage trees there are perhaps more than enough in our gardens, as they have been planted without due consideration of others, which by the beauty of their flowers as well as of their leaves are worthy of the closest attention from planters. As a matter of fact, their partial exclusion from some gardens is tantamount to lacking one of the most attractive features at this season of the year and onwards for several months.

So magnificent are the flowering trees that it is no light matter to decide with what a start ought to be made. This type of vegetation can be regarded from two distinct standpoints. 1, Trees that produce flowers and fruits; and 2, Those that are valuable by reason of their flowers alone. The former are generally relegated to the more utilitarian fruit and vegetable quarters, but at the same time it should be remembered that they have an exquisite beauty, of which no exact counterpart can be found amidst trees that produce flowers only. What is more beautiful than an Apple, Pear, Plum, or Cherry tree when the branches are wreathed in delicately tinted or pure white flowers? Surely those plants which combine to perfection the ornamental as well as the useful are deserving of as prominent a position as those that have the former alone to recommend them! Look at the Siberian, the Dartmouth, and John Downie Crabs. Are they not absolute perfection?

That there are gardens where fruit trees are utilised for the embellishment of various positions is readily acknowledged, but that these are too few is an incontrovertible fact. Every belt of trees that forms a background for lawns or shrubberies ought to number amongst its occupants a certain proportion of fruit bearers, not necessarily for their harvest burden, but for the flowers they give in their slightly varying seasons. Anyone who has visited many gardens can readily call to mind positions in which an Apple or a Pear, a Cherry or a Plum would have added very considerably to the existing beauties, and would, mayhap, have put that finishing touch on the whole that proclaims the artistic mind. The several Crabs are more commonly seen, but they have yet to be planted by thousands before they have received the notice to which their merits justly entitle them.

Closely related to the trees that have been briefly alluded to in the foregoing paragraphs, but differing from them in the fact they are essentially flower producers, we have the *Prunus*, *Pyrus*, and *Cerasus*. At the moment of writing these in some districts at any rate, are most strikingly handsome and adorn our gardens as nothing else possibly could do at this season of the year. That simple green for which we admire the many foliferous trees acts as a foil for the others round, and throws up their simple beauty in such a manner as to enforce not only the attention but the enthusiastic admiration of everyone. In every country garden, in every town park they may be found, but theirs is a charm that never palls, an attraction of which the eye can under no circumstances of time, or place, or quantity become fatigued. Separate the green leaves from the various coloured flowers, and the soul, as it were, of the picture would be gone. To venture to give names would be an error of judgment, as it is not now proposed to copy the catalogue, but to enter a plea for genera which, if they have not been really neglected, have had that scant attention that is almost condemnatory in its faint praise.

Of a nobler type are the *Magnolias*, and of a constitution that renders them more aristocratic and less amenable to plebeian tastes. It is not everyone who can have a grand tree of *Magnolia conspicua* in their gardens, or even the more modest growing, though not less beautiful, *M. stellata*. Of the first named, or to give it a popular name, the Yulan, there are a few superb specimens here and there in gardens, but there might with advantage be many more. Unfortunately neither the type nor its varieties thrives in every garden. Then there are *M. Lenné*, *M. Soulangeana*, and *M. purpurea*, of which any or all will add to the charm of a garden, no matter how diversified, that does not already contain them.

Where is the garden that can afford to dispense with the *Laburnum*? A common tree this, but one that is without a rival in the production of superb racemes of yellow flowers. Varieties are fairly numerous, but general opinion it is safe to assert will favour the Scotch form—*C. alpinus*—whose flowers are superior in colour and form to the others. A specimen of the Snowy *Mespilus*, *Amelanchier Botryapium*, in a neighbouring garden, charmed the writer a day or two ago as being one of the finest seen in a not limited acquaintance of gardening and gardens. It was such a picture that words are quite inadequate to do justice to it. Would that it grew equally as well in every garden. Thorns, too, must not be forgotten, as they are very handsome, particularly, perhaps, when planted in clumps. The older varieties seem to be, in many districts, part and parcel of the landscape, and it is difficult to picture what some park land would be like without them. Though the older varieties in their very age have the advantage of the more modern introductions, they cannot compare with them in the excellence and the colour of the flower, and time alone will remedy the defect of size.

The Rose *Acacia*, which it will be remembered was illustrated in the *Journal* for March 8th last, is a tree that will always be regarded with admiration by many people who rightly look upon it as being practically indispensable in the pleasure grounds. *Robinia hispida*, to accord it its botanic appellation, with its racemes of rose pink flowers, is decidedly ornamental and useful, and practically the same can be affirmed of *R. hispida*. Reference was made in the opening paragraph of these notes to the astonishingly rapid growth made by the Chestnuts a few days ago, and they are again adverted to as being amongst the noblest of our specimen flowering trees. Then, too, they make magnificent avenues, but in either case they require an abundance of room if they are to show themselves to the best advantage. Limes, if a bee-keeper were wielding the pen, would probably have been placed first, on account of their value as honey and pollen producers, are trees that require plenty of space when they are singularly attractive. The Judas Tree, *Cercis siliquastrum*, must be regarded as a neglected tree that ought to be brought prominently forward. It is strikingly handsome when in flower, and is not rivalled by any other tree in the colour of its flowers, which is purple. These, by the way, are produced direct from the branches in a decidedly peculiar, but still pleasing manner.

If a writer ventured to omit from such an article as this the *Catalpas*, he would probably bring down upon himself the wrath of the London readers of the *Journal of Horticulture*, who are deservedly proud of the specimens in the gardens of the House of Parliament. These are magnificent trees, whether they are regarded for their foliage or their flowers or both, and it is a little surprising that they are not more commonly seen. Possibly every passer-by does not know that the trees he so admires beneath the shadow of Big Ben are *Catalpas*. The Tulip Tree, *Liriodendron tulipifera*, too, finds many admirers, but its beauty lies rather in its leaves than in its flowers. If the correspondent's suggestion (page 102) is adopted the Tulip Tree will perhaps be growing in all our streets during the next generation. It is time, however, to cease writing for the present, and if trees of undoubted beauty have been omitted it remains with other writers to make good the deficiency for the benefit of their fellow readers.—F. ROWE.

A New Daffodil.—At the recent spring show, which was held in Ballsbridge under the auspices of the Royal Dublin Society, Messrs. Hogg & Robertson, Dublin, displayed a few blooms of their new Daffodil Cloncurry. The perianth segments are curious; three of them are twisted, and the remaining ones broad and flat, the tortuous ones are likewise narrow. The large cup is a deep orange scarlet. Rumour places the honour of raising this variety to the late Mrs. Lawrenson of Salerno, Killiney.—A. O'N.

Acacia lophantha.—*Apropos* of your reply to "Miss," respecting the hardiness of *Acacia lophantha*, I cannot from my own experience regard it as hardy. On the contrary, when situated in Kildare a number of seedlings was raised annually for planting out in a sheltered nook devoted to subtropical gardening, and although these compared favourably with the usual bedding plants by withstanding early frosts, they invariably succumbed to even a fairly mild winter. As a decorative plant for house work it was at that time much used, but owing to closing up its foliage at night, and its appearance under artificial light, it was eventually discarded for *Jacaranda mimosæfolia*, a plant something similar in appearance but far superior to the *Acacia lophantha* has certainly an elegance peculiarly its own, but it quickly develops into a coarse habited plant under glass. It may also be remarked that its roots emit an offensive odour, very noticeable when the plant is turned out for potting.—K.

Prunus Amygdalus persicoides.—Of the many forms of the Almond which are cultivated for the sake of their flowers, this is perhaps the best for all-round purposes. It forms a well-shaped tree 15 to 20 feet high, of a rather stricter habit than the type. The flowers, which open in March, are of a deep rosy pink, and are freely produced on every part of the tree. It is extremely probable that this is the same plant as that which was described nearly fifty years ago as the Peach Almond, a supposed cross between the Peach and the Almond, and which was said to produce two kinds of fruit on the same tree, and sometimes on the same branch, one of which was fleshy and succulent like a Peach, but bitter; and the other hard and dry like the Almond, but both containing a stone with a fairly sweet kernel. As the plant which is the subject of this note does not fruit in this country, it has been impossible up to the present to exactly verify this; but whether a hybrid or no, it is a plant which is worthy of a place in any garden for the beauty and freedom of its flowers. It is propagated by budding or grafting on the common Almond.—J.

Town Front Flower Gardens.—To the credit of the present Mayor of Kingston-on-Thames, Alderman Moatt, is it due the fact that rather than spend money on food and wine he has instituted this year a front flower garden competition in the borough, finding the prize money himself. He is aided by Mr. A. Dean, who prepared the schedule, some members of the corporation and of the Chrysanthemum Society constituting the committee, with Councillor Thyne as secretary. The Mayor's object is to encourage flower gardening in the hundreds of forecourts of the streets, and thus help to beautify the town. As these forecourts vary in dimensions, though none are large, three classes have been formed—viz., those of 1 rod in extent, half a rod, and a quarter of a rod. There is also a further class for front window or house decoration. In all these classes the houses must not be rated over £20, so as to keep out the villas, which are outside the Mayor's intentions. It is also made conditional that no hired labour be employed in the planting or keeping of the gardens. Five prizes are given in each class, and they range from 20s. down to 4s., making up a total of £9 12s. 6d. A farther class is for workmen's allotments held under the corporation on the Fair Ground, five prizes being given in this case also. It is one of the unfortunate features in the allotments that because a statute fair is held on the ground in November the crops are of no value for the winter, having to be removed or destroyed. A good group of allotments that have permanence for the occupiers is badly needed in the town, but land is scarce, and building is proceeding rapidly in all directions.—OBSERVER.

A Warm Bath for Phylloxera.—A correspondent on page 351 tells us that "washing Vine roots with water at 110° will disinfect them from phylloxera." If he means by that the pest will be killed he has had a tenderer variety of it than the sample I had to deal with. In a very bad attack of the enemy, dipping the roots in warm water had no effect; but by letting them remain for a day in water, warm or cold, the lice appeared to succumb—were, in fact, drowned. Simply washing or watering the roots with water at 110° would be as likely to make phylloxera comfortable by a soothing bath as to rid the roots of the destructive parasite. Ammoniacal liquor, or gas water diluted with five volumes of clear water, was bad for the Vine louse and good for the Vines.—A VICTIM.

Planting Vines.—No doubt the practice described by "G. A." of washing all the soil from Vine roots, and spreading them out in the orthodox way has answered very well with him and other planters. A few years ago when planting a large vinery, a discussion was being conducted in the *Journal of Horticulture* on different modes of procedure. Reflecting that I had shifted fruiting Vines from 12-inch into 18-inch pots, and noted the advantage of it, I transferred a few Vines much in the same way to a border. The drainage was removed and some of the roots disentangled, also all loose surface soil cleared away, but the great mass of soil and the bulk of the roots were undisturbed. The growth these Vines made excelled those treated as described by "G. A.," and gave better crops earlier, without revealing any signs of weakness in subsequent years.—J. WATSON.

Phlox divaricata.—"F. R." speaks in terms of high approval of *Phlox canadensis* on page 351 last week. His description of the flowers—"bluish lilac of a shining hue"—would apply equally to *P. divaricata*. This North American species is, so far as I have seen, and I have seen many, one of the finest spring flowering Phloxes in cultivation. The plants are not creeping in habit, but the stems, about a foot high, more or less erect, and in the aggregate forming perfect bouquets of well-formed flowers of the colour above described. I think I have read of this Phlox being extensively employed at Belvoir Castle, which is famed for spring gardening. Since writing the foregoing I have referred to "Johnson's Gardeners' Dictionary," and gather that the proper name for *P. canadensis* is *divaricata*. When planted too late in the spring uniformly satisfactory results are not obtained.—R. HILL.

Forced Stocks in Spring.—At the present time few flowers are more appreciated than the delicately scented Ten-week or other forcing varieties of garden Stocks. Princess Alice for cutting purposes can scarcely be surpassed, and in vases of a suitable kind they are very effective as well as agreeable in dwelling rooms. One great point in favour of these Stocks is their adaptability for growing in small pots. Large 60-pots furnish capital plants and blooms quite as large as those growing in others up to 6-inch sizes. They are of easy culture, and anyone having a cold pit and greenhouse may grow them. Seeds are sown in June and July, so as to give a succession of bloom, and until the winter is advanced frame room only is given, as this insures dwarf, sturdy growth. They, however, endure gentle forcing well, and by these means an earlier and continuous display is maintained. There are other varieties probably as good as these, one particularly good Wall-flower-leaved I have seen, but whose name I cannot remember.—R. A.

Daffodils in Shrubbery Borders.—Where sufficient margin can be provided these make a beautiful display during the spring months, but in dealing with them I observe that they thrive much better in sunny positions than where they are shaded by dense shrubs or overhanging trees. There is no comparison between those grown in our garden in shade and sunshine. I refer more particularly to the variety *N. telamonius plenus*, for while others are planted in varying numbers, including the bright *N. trumpet major*, the double variety has the greater space devoted to it. In the open where the full benefit of sunshine is felt, and in soil enriched with decayed tree leaves, these are magnificent both in size and depth of colour. A background of shrubs affords excellent relief, and when the Daffodils have attained to strong masses are gorgeous in the extreme. Those having pots of forced roots may do well to plant them without disturbance in out of the way corners, where with light and suitable soil they will give telling bits of colour in spring; if not in the next year, they will in others to follow. They can either be planted now or in a dormant state in the autumn. From newly imported roots an immediate return is given, and once established they do not require disturbing for a few years, or until they have become too dense and overcrowded to give fine blooms. The finest flowers no doubt come from roots thinly disposed.—W. S.

The Royal Horticultural Society.

The Temple Flower Show, May 23rd, 24th, and 25th.

For the thirteenth year in succession the Royal Horticultural Society will hold its great annual flower show in the Inner Temple Gardens (by the kind permission of the treasurer and benchers) on May 23rd, 24th, and 25th.

Every year the desire of growers to exhibit increases, and the officials of the society have a very anxious task in endeavouring to do justice to those growers who regularly support the fortnightly shows of the society held at the Drill Hall, and yet at the same time to encourage others also to come forward.

The space is absolutely limited by order of the Temple authorities; no more or larger tents may be erected, hence every new exhibitor whose entry is accepted means curtailment of the space allotted to previous supporters.

A catalogue of the show is given gratis to every visitor, and will contain a notice of new and rare plants entered on or before May 15th; it will also contain a programme of the music to be performed each day by the band of her Majesty's Royal Horse Guards (Blues).

The judges will meet at the secretary's tent at 10.30 A.M. on May 23rd, at which hour punctually the tents will be cleared of all exhibitors and their assistants.

The Fruit, Floral, and Orchid Committees will assemble at the secretary's tent at 11 A.M. sharp, and the show will be opened at 12.30.

All plants for certificate must be entered on or before Friday, May 18th, addressed—The Secretary, R.H.S., 117, Victoria Street, S.W. They cannot be entered under any circumstances on the day of the show.

Scientific Committee, April 24th.

Present: Dr. Maxwell T. Masters (in the chair); Mr. W. Bateson, F.R.S.; Rev. W. Wilks, Prof. Church, Dr. Müller, and Mr. McLachlan.

Ash-shoots barked by hornets.—Mr. McLachlan exhibited growing shoots completely ringed by the hornets. This is apparently a rare occurrence, but the chairman recorded a similar instance which had come under his notice in Messrs. Lee's nursery at Isleworth many years ago.

Fasciated roots of Aloe sp.—From Mr. Justus Corderoy came specimens of pot-bound Aloe-roots, some of which were markedly fasciated. Fasciation so common in stems is very rare in roots, only two or three instances being recorded—viz., in Spiraeas, and in some epiphytal Orchids.

Umbellate Primrose.—Mr. Arthur Sutton sent a flower of this variety, at one time confused with the Oxlip.

Evolution Committee.—Mr. Bateson attended as a delegate from the Royal Society to bring before the members of the committee some explanations of the kind of work which it was hoped some cultivators might be disposed to undertake, with a view to the accurate observation, and, where possible, measurement of variations in the plants under their care. A raiser of Chinese Primroses, for instance, might keep under observation all the variations that arise, measure and draw or photograph them before throwing them away, so that we should have some record of the intermediate stages between the original forms and the variety thought worthy of perpetuation.

The Views of Experts on Limpsfield.

Mr. Edwin Beckett.

I VISITED the above site on Wednesday, April 18th, as requested in company with Messrs. Bunyard, Paul, and Poupert. We carefully investigated the site, and I beg respectfully to submit my report on same.

Arable field marked on plan 344. Test hole No. 1, a good depth of heavy loam, resting on strong sandy clay subsoil. No. 2, test hole ditto ditto, position south and south-west, protected from north and east, unquestionably very suitable for Strawberry culture. Field marked on plan No. 343, sloping to south-west, test hole practically the same as the last.

Field No. 323, facing south. Test hole No. 4, slightly lighter and better depth of surface soil. A small portion of this field is water-logged owing to the water courses being blocked.

Field No. 342, grass pasture, south aspect. No. 5 test hole. A similar kind of soil to the last and also badly drained.

Field No. 324, grass pasture, sloping to south-west. No. 6 test hole. Fully a foot of surface, strong loam of good quality, subsoil sandy clay. We tested this field at four stations and found it to be all of about the same quality.

Field No. 310, now cultivated as a Hop garden on southern slope. Test hole No. 7. Excellent depth of surface soil of a much lighter quality. Test hole No. 8. About same nature as foregoing.

Field No. 311, arable, good light sandy loam resting on rock, falling rapidly to south-west; about half-way down a better depth of soil and of superior quality.

In my opinion nearly the whole of the land requires to be thoroughly drained. No difficulty should be found in carrying this out, as the lie of the land lends itself admirably for this purpose. Most of the land also is in a very poor condition, and would require thorough cultivation and manuring. The variety of soils and positions would make the site an admirable one for an experimental garden. The whole of it is particularly well situated and protected from north and east winds, and hardly any fruits, flowers, or vegetables should fail to do well upon it, Rhododendrons, perhaps, excepted.

I consider it an ideal soil for all kinds of vegetables, and apparently a good supply of water could be stored, and a delightful bog and water garden might be formed. The climate appears to be all one could wish, and the site could be made both interesting and beautiful.

Mr. George Bunyard, V.M.H.

THE upper portion of the farm is some 400 feet above the sea, and falls gradually to some 300 feet, the whole (speaking generally) having a most desirable exposure to the south. The estate is naturally sheltered from the north and east by the adjacent hills and woodland, and the spinneys and tall hedges provide all the shelter required for fruit and vegetable crops. I took notes of the soil in about eighteen positions, but as some trials were exact duplicates I only record nine instances.

Starting at the lower end next the main road in field 341, now in Clover and seed, the soil proved to be an unctuous heavy loam, with a subsoil of pervious sandy clay, which can readily be improved by drainage. A grand position for Pear trees on Quince stock, Black Currants, and Strawberries of the latest sorts and the British Queen race.

Field 343, in Wheat, has a slight slope to the west, and is a trifle lighter in texture than 344. A grand spot for Roses.

Field 323 in grass, lies at the lowest point, and although the drains and ditches had been neglected, I found no part saturated with water, and the opening of the ditches and draining will make this a valuable plot for vegetable crops, as it contains more humus than the previous plots.

Field 342 in pasture, is very similar to 323, and only the neglect to keep the drains open causes it to be damp, as the subsoil is not impervious, and there are two outfalls for drainage with a fall of 2 feet to provide ample outlet for any winter rains. This would make a fine pinetum.

Field 324 is a fine pasture field, falling from east to west. The soil is a very rich, heavy loam, eminently suitable for fruit of all kinds, as the surface soil is deep and the subsoil is lighter than in other parts. I consider it the best field on the farm.

Field 310 is in Hops, and the necessary culture for the crop has rendered the land in good heart and condition, and I should fix on this spot for an experimental orchard or plantation. The top of this position is even better than the lower part.

Field 311A is in corn, and the upper portion is on the bedrock about 2 feet, and is of a lighter description than any yet noticed, eminently suitable for bulbs or root vegetables, as Beet, Carrots, &c., also for Nut bushes and Plums, or kidney Potatoes.

Halfway down field 311B the land becomes heavier, and is then fine retentive loam suitable for Pea and Bean trials, Apple culture, and main crop Potatoes and Strawberries.

At the base of field 311C and towards the west it becomes heavier and requires to be ameliorated by drainage, although fine land for cereal crops in its present state. There is a 2 feet fall into a ditch on the other side of the hedge ample for all drainage purposes.

Field 311 is not well farmed and will require a heavy coating of manure to bring it into full use.

The present oast house, if Hops are not continued, will make a capital fruit store on the top floor, and Potatoes and roots can be kept below.

GENERAL REMARKS.—I consider the site an ideal position for an experimental garden for horticultural purposes as there are several features which can be made the most of. For example the roadsides can be used as an arboretum (forest trees, &c.). The field 323 or 342 for a pinetum, other spots suggests a collection of flowering shrubs, a salicarium (or Willow bed) for the purposes of correcting the nomenclature of this useful family and for selecting the best Osiers for basket work, trials of suitable fancy hedge shrubs, trials of artificial manures, &c.

The water supply, rising at a fair altitude, can be utilised by gravitation for greenhouses, vineries, &c., ornamental pond for aquatics, tanks for the smaller water plants, and water for all purposes can be stored where desired.

There is an ample choice of soil for all the families of herbaceous plants. Sandstone rock at hand suitable for rockeries, alpine garden, &c., and positions for every kind of hardy fruits and vegetables. From the conditions of the old trees in the garden (uncalled for) it is evident that fruit will succeed in the district, and younger trees planted near were evidently in congenial soil drainage. A complete system of drainage will be required, and the trend of the land favours this operation, as it falls naturally to the outlet.

Mr. George Paul, V.M.H.

As requested, I inspected on Wednesday, 18th of April, the farm land at Limpsfield, by Oxted, offered to the society. My instructions, I understand, were to report upon the lay of the land, its quality, condition, and suitability for the culture of fruit, vegetables, and in my case more especially of flowers, Roses, herbaceous plants, and similar plants. Messrs. Bunyard, Ponpart, and Beckett are each sending a separate report, but there will be found much upon which after discussion and a frank interchange of opinion we were agreed.

The side is a southern slope of a continuous range of hills bearing to the east upon the lower greensand and ascending half up the hill, and thus sheltered thoroughly from the north and east by the higher position of the slope. The meadows referred to further on lie at the foot of this slope, and are consequently, as regards 323 and 342 of the ordnance survey map, the recipients of the storm water of the somewhat basinlike shape of the higher slopes. This accounts for a fact which we gathered from inquiry of the neighbouring cottagers that a part of these two fields is subject to an occasional flooding after sudden storms, but which quickly passes away (these fields having a thoroughly good outlet, now needs clearing), but which I consider as a valuable element in the estate for water supply and other purposes.

The estate is entered through two fields with long frontages to the main road across the extensive adjoining commons from Oxted station. Field 344, of many years' standing (old pasture), falling slightly to north and foot of hill. Field 343, the adjoining field. Arable, under Wheat. Frontage to road. Same fall, fairly clean, and fair crop. Field 323, adjoining field to north of 343, with entry over roadway at the east side of 343, is old pasture with a covered drain or culver to take the storm water from the other sloping basin to the outfall ditch which is by the east side of the entry road on 343. Field 342, old pasture, with a slight fall to the ditch referred to on the western side. These four fields are all more or less of one level, the flat land at the foot of the three sharp sloping fields lying above them. This soil is a heavy clayey loam of good fertility, of about 1 foot in depth, the subsoil being the sandy clay, or moist sand of this formation. I should say this portion of the estate would grow Roses freely, herbaceous plants, evergreens, and Pears and Apples amongst the larger fruits, Strawberries and bush fruits amongst the smaller fruits; and with regard to vegetables, it would be good Pea, Bean, and Broccoli soil.

The land requires draining, and had I to deal with it for practical nursery or market garden work, I should along its centre and in the lowest part of the two last named grass fields make a wide ditch or small mote, with a controllable outfall into the brook near the road, and which I understand flows into the Eden; and so I should secure a water storage supply, which could be pumped to the highest level of the estate, and so lay the whole of the experimental garden under water control. The brook which, after turning a ram for the owners of the higher land, flows through the estate might, I think, be used to lift this stored water to this highest point alluded to. Such a basin would be invaluable in a trial garden for the growth of the newer Water Lilies and other water plants. Altogether, I conclude this water supply to be of value for a garden applicable to experimental purposes.

The three additional fields are of a totally different character, they form the sloping sides of the land basin, of which the lower fields are the bottom. Field 324, old pasture in good condition, facing S.W., rising quickly some 50 feet; soil slightly lighter than the preceding fields, subsoil rather charged with the water from the upper greensand lands requires, as do also the adjoining sloping fields, good subsoil drainage; fine Strawberry and fruit land. Field 310—Arable under Hops, which are breaking strongly; the brook in question falls rapidly along its eastern side. Slope to the east rising rapidly to a level of 400 feet; the soil is somewhat lighter but of greater depth, and the subsoil is decidedly more sandy, I should consider it, as far as regards its suitability for fruit culture, as good Plum, dessert Apple, and choice Pear land. At the top of the field, lying as it does close to the stone Cherryland, I think Tea Roses, shrubs, and Conifers requiring lighter soil and hardy plants, with like requirements, should do well. Field 311—Upper part of this field light sandy loam, resting 1 foot above stone used for building.

Arable, with a fall of some 200 feet to the meadows below. A fertile lighter soil, with its different quality invaluable in such a garden. Half-way down the slope the soil changes and gradually approaches that of the lower level; it is here somewhat moist from the flow of water from the rock, but needs only drainage; this difference of soil again affords from its variety opportunities for trial of fruits in the different lighter or heavier soils. Roses would do well here, Conifers on the rock underlying other parts of the field, and it is either here, or in the exposed rock hill side by the farm house, that alpine plants could be tried.

Conclusively, I look on the soil as good sound heavy soil; the large proportion of old turf is most valuable; the sheltered positions are beneficial; its water supply valuable and available, and its difference of altitude, slopes, and variations of soil are essential for the purposes for which the garden, as an experimental garden, is required. The whole estate from its altitude is, I should imagine, above the dangers of spring frosts, but I cannot be positive as to this.

Mr. Wm. Poupart.

ACCORDING to instructions I attended on April 18th at Chartland Farm, Limpsfield, Surrey, with a view to reporting as to its adaptability for a fruit, vegetable and flower garden. I made a careful inspection with the following result:—

The farm consists of about 50 acres, and is situated in the lower and middle portion of a sharp rising valley, mostly facing the south and well protected from the north and east. It is divided into eight enclosures which I report on separately, using the numbers on ordnance survey.

No. 344.—Wheat stubble, a comparatively flat field; has about 10 inches of heavy loam on slightly sandy clay. No. 343.—Young Wheat, very slight slope to south and south-west; soil the same as in 344. I consider these two fields well adapted for the growth of most vegetables, fruit, and many flowers. No. 323.—Grass. Soil a medium loam on sandy clay. This field shows signs of wet in a portion running down the centre.

No. 342.—Grass, soil same as 323. This field is also very wet through the centre part. These two fields are the middle of the lower part of the valley, and form the natural outlet for the water from the whole. The drains appear to have been sadly neglected, in fact some have almost disappeared. I am of opinion that with good open ditches and the land well drained and cultivated these fields would make excellent garden ground. No. 324.—Grass field, sharp slope facing S.W. Soil 12 inches good loam on stiffer loam over sandy clay, this is a capital piece of land. No. 310.—Hops, slope facing S. and E., soil 12 to 15 inches good medium loam. No. 311.—Large arable field, good slope to the south, soil upper part (about half) 12 inches light sandy loam on rock, lower part little stiffer on sandy clay, about two acres of bottom corner of this field show signs of wet, could be easily drained in conjunction with 323. These two fields, 310, 311, would do well for fruit, vegetable and flower growing.

The land has been badly farmed, the drainage utterly neglected. I am of opinion that with proper attention to the drainage (the final outlet for which appears to be ample) and good cultivation the land would make a good all-round garden.

Mr. Arthur Sutton, V.M.H.

I HAVE very carefully examined the site with the plan. In view of the fact that this site is recommended by others who have seen it, I feel most reluctant to offer any adverse opinion. In the first place Oxted itself cannot be said to be inaccessible from London, as several trains make the journey in from forty-five to sixty minutes, and if any good site had offered at Oxted, it might have been as suitable a locality as many others. The case is altogether different when we find that the site itself is from two and a half to three miles from the station, and the road so hilly that a cab takes twenty five minutes to cover the distance. This alone means that every ton of building material, or coal, or coke, or manure, would cost 2s. 6d. or 3s. to cart from the station. I was nearly twenty-five minutes driving with a fairly good horse to the Charing Cross Home, and more than twenty-five minutes driving back from the southern end of the land.

But possibly this might not be considered a very serious objection if the land itself were suitable for gardening operations. It is in this connection that I feel bound to offer the very strongest protest I can against the scheme. Although the weather was wet in town, it was fine at Oxted; and apart from some rain yesterday they had but little or no rain for some weeks past; notwithstanding this, I found the whole 50 acres, except the Hop garden and the upper portion of the field adjoining (No. 311a), very wet and sodden; when after the drying winds we have had, it ought to have been in fair working order. No doubt the upper portion of field No. 311—say about 4 acres—might be worked fairly easily, and as its tilth was satisfactory, a seed bed for corn or other crops might be formed soon. All the rest, however (311 b), below the brow of the hill was a cold, heavy, sticky soil; and as the plough turned it up, the furrows had that pale yellow-and-white appearance so characteristic of unhealthy and unproductive clay land. When I mention that it is "four-horse" land, and that four horses could with difficulty draw the plough, it will be understood what I mean. The furrows turned up presented a hard, sticky surface, which it would take weeks to render fit to take any crop, and the man at plough said it always took four horses to work. The Hop garden (field No. 310) is very strong land, and may grow Hops well; but even so, it is not to be compared with the rich, deep, friable Hop soils generally found in Kent and Surrey.

The land under grass (about 17½ acres) I am confident can never be tilled except at a great loss, and certainly could never be made good garden soil. I made a close examination of each grass field. The only one with anything approaching a good turf—i.e., turf which indicated useful grasses, was No. 324. This, however, although on rising ground, was as wet as a sponge, even in its higher portions, and I consider the soil is so retentive in character that no amount of drainage would enable the finer grasses to become permanent. As it is at present, moss is found all over the field—a sure indication of excessive and stagnant moisture. Fields Nos. 323 and 342, though not now flooded, must sometimes be liable to flood. Water now stands on them in places

and several furrows in each field are full of water. So completely water-logged are these two fields that the grass has assumed a rusty brown colour, due to excess of stagnant water, and both fields, but especially No. 323, are covered in places by a growth of rushes, also due to being water-logged. The only portion of field No. 323 where the grass is fairly good is marked "C" on the plan—about three-quarters of an acre. The remaining two fields (Nos. 343 and 344) are only suitable for Wheat, and then only in a hot dry season. On No. 343 is a very thin plant of Wheat, and its thinness is due probably to the wet weather of January last. No. 344 is a Wheat stubble, exceedingly foul, and with a very scanty plant of Clover. Even if these two fields were likely to prove good garden soil, they are too far removed from the best portion of the land at the top of the hill to be conveniently tilled. As a matter of fact, the elevation of the land is such that the grass fields form a natural basin or reservoir, where the water from the surrounding hills collects, and, having no outlet, becomes stagnant and sour. From my knowledge of the value of land in other counties, I am confident that for agricultural purposes all the fields comprised in the 50 acres, with the exception of the Hop garden and the upper portion of No. 311, would be dear at anything over £35 per acre.

I understand the scheme has recently been modified, in so far that it is not now proposed that the Royal Horticultural Society should purchase the Caxton Home, or attempt the formation of any horticultural school. Were it otherwise, I should think the £3500 named as its price quite £1000 too much, whatever it may have cost to build. I have only seen two sites. Oxted is one I feel bound to oppose most strongly, whether as a member of the council or as an ordinary Fellow, and I feel sure that any expert authorities, such as the agricultural professors at Cirencester or Downton, would agree with the opinion I have given above, as would also any market gardener who cultivated for profit. If samples of soil are to be taken for analysis, I would suggest that someone conversant with the methods usually followed be employed to take the samples. Very few fields are alike in all parts, and three or four samples from each field would be needed to obtain any reliable data. Those accustomed to soil analysis would take samples from the most dissimilar portions of each field, as by this means only can a true estimate be obtained. But whatever the result of the analysis may be, the natural formation of the land at the foot of the hills, especially of the meadows, at Oxted is such that it can never become garden soil—of even fair quality.

I do not wish for a moment to place any hindrance in the way of the council in carrying out well-considered schemes, and rather than do so in the present instance would readily resign my seat. In fact, such a course seems inevitable if the council adheres to the resolutions passed on Tuesday last, unless I propose an amendment at the meeting to be held on the 25th inst., which I should be very unwilling to do. But for the importance of the matter at issue, I would sincerely apologise for presuming to occupy the time of the council with this letter, the writing of which at best is a most unpleasant duty. I am aware that as the option to purchase is for a limited time only, and a general meeting is summoned for the 25th inst., the council is placed in a somewhat difficult position. In view of the fact that it is the centenary of the society we are proposing to celebrate by a scheme which is to be permanent in character, I would suggest that two duly qualified and experienced land agents or surveyors be appointed immediately to examine the 50 acres at Oxted, and report upon the fitness or otherwise of the soil for the purposes of a Model Garden of Horticulture. The surveyor should also be instructed to determine the actual value of the land for agricultural or horticultural purposes, as it is obvious that the fancy prices obtainable for building sites on the crest of the hill are no guide whatever to the value of the 50 acres in question, all of which lie below the hill top, and afford no site for building, unless it be for a modern farmhouse, to take the place of the primitive and more or less dilapidated buildings and cottages now standing. The following land agents and surveyors are men of wide experience, and of high standing in their profession:—Messrs. Rawlence and Squarey, 15, Great George Street, Westminster, S.W.; and Messrs. Clutton, 9, Whitehall Place, S.W.

It may be technically correct to say that at the annual meeting, the Fellows, by adopting the report, committed the society to the formation of a new garden as the best means of celebrating the centenary, but if so, I am confident that few, if any, of those present thought for a moment their vote would have this result. I very much doubt whether many Fellows could be found who considered the purchase and laying out of new gardens the fittest and most useful way of celebrating so important an event. There has been very little time at recent council meetings for the discussion of the "new gardens," and perhaps this is why the council as a body are entirely in ignorance as to how these gardens, if obtained, would be worked or organised. If the new gardens were managed on similar lines to the present gardens, where the work consists chiefly of trials of at least doubtful utility, and the cultivation of large quantities of Grapes and other fruits which are marketed, I do not hesitate to say that the result would not be worth the outlay. The present Chiswick Garden costs £1400 a year to maintain, and the new one would, of course, cost double or treble this amount. I venture to think that no adequate results could be obtained from the new gardens unless placed under an experienced director equal in technical horticultural knowledge to Mr. Jas. Hudson, Mr. Owen Thomas, or Mr. G. Wythes—men who, though loyal to any expressed

wish of the council, would be sufficiently independent to initiate and carry out work which it is impossible for the council itself to find time even to suggest. It may be objected that these are matters of detail, but, unless the Fellows are assured that the council are prepared to organise the new gardens on a totally different system to that at present adopted, it is very unlikely their support can be secured. Supposing that instead of the garden it was desired to celebrate the centenary by providing a large horticultural hall, with committee rooms, offices, &c., would not the £3000 or £4000 a year, which the new gardens must in any case cost to maintain, provide the interest for the capital which might be borrowed for erecting the hall?

(1) I cannot think that the purchase of a new garden is the best means of celebrating the centenary of the society; and (2) that if any new gardens were considered necessary by the Fellows, the Oxted site is one which, in my opinion, is extremely unsuitable, and certain to involve the society in a very large outlay, for which there will be no adequate return; (3) and further that as the centenary will not take place until 1904, it is unwise to decide so hurriedly on any site at the present time.—("The Gardeners' Chronicle.")

The Promise of Spring.

A FLOOD of sunshine has recently been poured upon the land, and to its quickening influence vegetation has responded in a way which should make our hearts glad. The dark, cold days of winter, and the biting winds of early spring, are forgotten as the eye rests upon the verdant pastures, or the gay flowers and advancing crops in our gardens. Such signs of activity have been watched and waited for by young and old in our island home, but, perhaps, by none so anxiously as those gardeners who have to provide an unfailing supply of flowers, fruits, and vegetables. The long delayed supply of flowers from the open air has caused many to be at their wit's end to satisfy requirements, as the glass houses are at this season largely occupied with plants intended for the flower garden in summer; and with a good collection of herbaceous and flowering trees one can generally rely upon getting large quantities of flowers in the open air by the middle or end of March, yet this year many gardens were almost flowerless then. Fresh green vegetables have also been extremely scarce; the early Broccoli were in many instances ruined, and the later ones presented a sorry appearance, and seemed rather to grow less each day than to advance to maturity. All is, however, now changed; early Cabbages are growing apace, and what Borecole still remain begin to grow with the fresh greenery of spring.

We have now entered upon a critical season in the gardener's year; his hopes and fears during the next few weeks will be largely influenced by the state of the weather, and it is in connection with hardy fruits that we are, to the greatest extent, dependent upon the weather samples which are meted out to us. Just now the promise looks particularly bright, as fruit trees are either laden with blossom, or are showing a wonderful abundance of swelling flower buds. Seldom have I seen trees look so uniformly promising, and as the late spring has retarded the opening of the flowers, we may at least hope to be spared from ruthless frosts in May, or that they will not occur at that critical time when the blossoms are fully expanded. During my limited travels in the Midlands recently I saw several fruit plantations which looked extremely promising, the Apple trees especially so, as the leaves were just unfolding and displaying a wealth of plump flower buds. It is also encouraging to note that a considerable amount of planting has been done, and the young trees show signs of careful attention, in marked contrast to many old orchards met with. In the young plantations the thinning of the branches has been judiciously carried out, and there are evidences in many directions that the sound knowledge, which has been disseminated in many ways, is being acted upon. As one who has long been interested in fruit culture, these signs of improvement were especially welcome to me. This season should be a noted one for Gooseberries, as all the bushes I have yet seen were loaded with embryo fruits. Peaches, Apricots, and Nectarines, on south and west walls, have also set well, even in cases where no protection has been given, but those on east walls seem to have suffered severely from the cold winds. The soil has, up till now, kept uniformly moist, and I am convinced that it has greatly favoured a good set, as dryness at the root during the blossoming time is frequently the cause of a scanty crop, although it is invariably attributed to frost.

It is wonderful how quickly the soil has dried of late, and this has afforded excellent opportunities for keeping the hoe going in all departments of the garden, so as to take full advantage of sunshine by allowing it free access to the soil, where its warmth will help forward the progress already made. Gardens generally are now free from weeds, trim and neat, so that, notwithstanding the fact that the

season is late, the prospects for the coming season look bright, and work which a short time ago was sadly in arrears is well in hand, and this will help gardeners to look forward without misgiving to the busy time of the bedding-out season.

The snows, frosts, and biting winds of winter play their part in ameliorating and sweetening the soil; the fickle showers of April freshen and speed to luxuriance the tender growth of spring, raising our hopes high with the prospect of a bountiful harvest. May the year bring to the followers of our ancient art a full measure of that bright promise which stirs us to activity in the days of spring.—ONWARD.

Bulbs in Victoria Park.

It is extremely doubtful whether dwellers in the country, with its wealth of vegetation and pure, health-giving air, can realise how the parks and gardens of the metropolis are appreciated by Londoners. This is perhaps especially the case at three seasons of the year—1, when the bulbs are in flower in the beds; 2, when the summer flowers are at the zenith of their beauty; and 3, when the Chrysanthemum is the flower of the hour. At other times the parks have their thousands of visitors, but at these periods it is quite a pleasure to see the crowds round a particular bed or flower, and to hear the criticisms that are passed on the work that has been done. The latter show how deeply interested the visitor is in his flowers, and how keenly he desires his particular park to be ahead of that of his neighbour in its bulbs, summer flowers, or Chrysanthemums.

The more encouragement the London County Council can give the masses in this direction the better, as no one can doubt that flowers and their associations have an excellent effect on every mind. The district in which Victoria Park is situated is one of the most crowded and unsavoury in the metropolis, but it accommodates many thousands of horticulturists, at least one must suppose so who mingles with the crowd and hears the varied expressions of opinion. The people, as a rule, are remarkably just in the views they hold, and are equally as prompt in seizing upon a good point as on a bad one. To a large degree this faculty of intelligent criticism has been engendered by the County Council and its various superintendents, who have laboured assiduously to educate the masses up to what is permissible and what incongruous in the planting of beds with various flowers.

This season east and north-east London has had to wait a long time for the display of bulbous flowers, for which Victoria Park has become so famous of late. It must be several years since the season was so late, and certainly the bulbs have been over in some years by the present time. And yet they all came out within a week. One day there was scarcely a flower to be found, and one week later there they were in their thousands. A few days ago, when I had the pleasure of seeing them, they were probably at their best, with the exception of a few beds of Tulips, which had not then fully developed. With some of the Hyacinths it was almost a case of here to-day and gone to-morrow, so short was their reign, but in this respect the varieties differ very materially, some remaining in good condition for a much longer time. No doubt the peculiar season has had much to do with this, as until the week referred to as bringing them on with such astounding rapidity the weather had been particularly uncongenial to this, and, indeed, all forms of vegetation as well as to mankind.

Probably if a plebiscite could be taken it would be found that the most popular bed of all was one in the space near the Palm house of Narcissus Emperor. It was at the time of my visit really magnificent, and it would scarcely have been possible to find its superior in any park or garden. The popular bicolor Horsefieldi, too, was in excellent form, and as usual claims a large share of admirers. Barri conspicuus is in its way unrivalled, and it might advantageously be used with far greater freedom, both in respect of the number of beds planted and in the number of bulbs allocated to each bed. The bed observed of Sir Watkin, which many people regard as one of the finest Narcissi in cultivation, was not by any means satisfactory, the plants varying in height to a remarkable degree; the flowers again differed in size, form, and colour, and with few exceptions were not thrown up above the leafage, as is the normal habit of this noble flower. The splendid yellow maximus was in capital condition, and made itself very conspicuous.

Amongst the Hyacinths the finest bed was undoubtedly that of the King of the Blues. This is a decidedly ancient variety, but as a dark blue for bedding it is still difficult to beat. The trusses on the plants in Victoria Park were splendid. The only other Hyacinth worthy of note was Gertrude, the charming rose coloured variety, which has been familiar to flower gardeners for years. The Tulips were not, as has already been said, up to the mark, but several promised well, such for example as Van der Neer, Chrysolora, Vermilion Brilliant, Keizerskroon, Proserpine, Pottebakker White, and Rose Grisdelin. These only wanted a few more days of warm sunshine to bring all their brilliant beauty on to the scene. The whole display is fine for the season, and should prove a source of satisfaction to the council; Mr. J. W. Moorman, the superintendent; and the inhabitants of the neighbourhood.—WANDERER.

The Hailstorm Insurance Corporation.

THE fifth annual general meeting of the Nurserymen, Market Gardeners', and General Hailstorm Insurance Corporation, Limited, was held at the new offices of the corporation, 41 and 42, King Street, Covent Garden, London, on Tuesday, 24th April, 1900. Mr. H. B. May presided (in the absence of Mr. Harry J. Veitch, who was in Palestine), and there was a good attendance of shareholders. The chairman gave some interesting figures, showing the growth of the premium income and business, as follows:—

Year.	Policies in force.	Premium Income.	Square feet covered.	Value Insured.	Claims paid.
		£ s. d.		£ s. d.	£ s. d.
1895-6	235	681 1 9	10,408,161	135,215 16 0	283 17 4
1896-7	346	889 11 5	13,886,095	179,366 11 1	Nil.
1897-8	550	1360 17 0	20,098,104	263,590 19 1	1532 17 5
1898-9	749	1736 0 6	25,619,760	343,439 7 8	Nil.
1899-1900	825	1962 0 1	28,855,076	391,202 15 4	Nil.

The working expenses had been reduced from £40 10s. 3d. per cent. of the income in 1895-6 to £18 3s. 6d. per cent. in 1899-1900.

The report was unanimously agreed to, as was the recommendation of the directors, that a dividend at the rate of 5 per cent. and a bonus of 2½ per cent. per annum be paid, and that £800 be placed to the reserve fund, and the balance £375 10s. 4d. be carried forward. A further issue of 5000 shares of £5 each had been made at a premium of 4s. per share. The issue had been more than subscribed for, and applications for shares were received too late. £1 per share had been called up, received, and invested. The subscribed capital was now £50,000, and the paid up capital £10,000. The premiums on new issue had been placed to the reserve fund after deducting the cost of the new issue.

Since the financial year had closed a claim for damage to glass by hail had come from Kirkwall, Orkney Isles, and had been promptly paid.

Horticultural Shows.

National Primula and Auricula Society, Midland Section.

April 25th.

SUPPORTED by a most influential list of growers, the initial exhibition proved an encouraging success, and though not so large as the parent society's recent show held in London, several of the varieties were pronounced to be equal in quality, as instanced by the premier prize plant Mrs. Henwood, and which specimen had also taken the premier prize at the Drill Hall on the previous day by Messrs. Phillips & Taylor, Brockwell, who were also accorded chief honours for six Show Auriculas, dissimilar, with George Lightbody, Marmion, Miss Barnett, Rev. F. D. Horner, and a seedling unnamed; the second prize fell to Mr. A. R. Brown, Handsworth, and the third to Mr. W. B. Latham.

Messrs. Phillips & Taylor were first for four varieties, with Acme, Mrs. Henwood, Miss Barnett, and Shirley Hibberd; second Mr. J. Clements, Harborne; third Mr. J. Stokes, Harborne; fourth Mr. A. R. Brown, Handsworth; and fifth Mr. R. Holding, Ballsall Heath, Birmingham (the enthusiastic secretary). For two plants Mr. R. Holding and Mr. J. Stokes were placed equal first.

Single plant green edge Mr. Ben Simonite led the way with Ossian, second and third Mr. A. R. Brown, and fourth Mr. R. Holding. For a single plant grey edge Mr. A. R. Brown was first with Beauty; second Mr. W. B. Latham with Colonel Champney. Mr. A. R. Brown was placed first in the white edge class with Acme, and Mr. J. Stokes third. In the self class, which was well contested, Mr. J. Clements was first with John Spalding and Gerald; second Mr. A. R. Brown with John Spalding and Mrs. Potts; third Mr. A. R. Brown; fourth Mr. R. Holding; and fifth Mr. F. T. Poulson, Stafford.

Alpines were exceedingly good, and for six Mr. A. R. Brown was placed first with Dean Hole, Mrs. Gorton, Thetis, Mr. Martin Smith, R. Gorton, and J. F. Kew; second Messrs. Phillips & Taylor; third Mr. R. Gorton; fourth Mr. R. Holding, and fifth Mr. J. Clements. For four plants Messrs. Phillips & Taylor, A. R. Brown, R. Holding, R. Gorton, Eccles, and J. Clements were placed as in order named. For two plants Mr. W. H. Twist, Curall Heath, was placed first; Mr. W. W. Cheshire, Edgbaston, second; Mr. Poulson third. For a single plant with gold centre Messrs. R. Gorton, H. R. Brown, Phillips & Taylor, J. Clements, and W. W. Cheshire were the respective winners. For a single plant, light centre, the first and third prizes fell to Mr. A. R. Brown, the second and fourth to Mr. R. Holding, and the fifth to Mr. J. Clements. In the premier Alpine class Messrs. Phillips & Taylor were assigned the prize. For a pair of Alpines (for maiden growers) Mr. W. W. Cheshire and Mr. F. T. Poulson were the winners.

Polyanthuses were sparingly shown. For four plants, gold laced varieties, Messrs. Pope & Sons were the only exhibitors. For a group of Primulas or Auriculas Messrs. Pope & Sons were to the fore, with Mr. J. Clements second, and Mr. R. Holding third.

The Midland Daffodil Society.

April 25th.

FAIR as was the initial show held last year at the Edgbaston Botanical Gardens, the recent event surpassed it both in size and the general quality of the blooms. Several excellent seedlings came from Miss Willmott of Great Warley; Mons. R. Van der Schoot & Sons, Hillegom; and Mons. J. de Groot & Sons. Silver medals were awarded to two exquisite seedlings of Miss Willmott's—viz., Countess Grey and Mrs. Berkeley. A similar honour was bestowed upon Chaffinch, exhibited by P. D. Williams, Esq., St. Keverne, Cornwall. A special certificate was also awarded by the committee to Queen Wilhelmina, from Mons. J. de Groot & Sons.

The trade, as usual, made a brave display, and silver medals and special certificates were severally accorded to Messrs. Barr & Sons, London; Dickson, Ltd., Chester; Hogg & Robertson, Dublin; Thos. S. Ware, Ltd., Feltham; R. Sydenham, Birmingham; J. R. Pearson and Sons, Chilwell; R. H. Bath, Ltd., Wisbech; Pope & Sons, Birmingham; and Hewitt & Co., Birmingham.

The following is the prize list:—For a collection of Daffodils, fifty varieties (exclusive of the Polyanthus section), the first prize, silver cup, was worthily awarded to Mr. R. O. Backhouse, Hereford; second to Mr. P. D. Williams, St. Austell, Keverne; third, Rev. J. Jacob, Whitechurch, Salop; and fourth, Mr. W. A. Caldecott, Coventry. For twelve distinct true trumpets the premier honour was conferred upon Miss F. W. Currey, Lismore, Ireland; second, Mr. W. J. Grant, Newport, Mon; third, Mr. H. B. Young, Methorthingham, Lincoln; fourth, Miss M. B. Crawford, Ardlamont, N.B.; and fifth, Miss Mabel B. Crawford, was again successful. For six varieties (trumpets) Mr. A. Cryer, gardener to J. A. Kenrick, Esq., Edgbaston, was placed first; while Mr. Leonard of Brentwood, and the Rev. G. F. Eyre, Bowdley, were accorded equal second; fourth, Mr. C. Dawson, Penzance; and fifth, the Bishop of Worcester, Hartlebury Castle.

For twelve varieties Medio-Coronati, Miss F. W. Currey was again to the fore with excellent blooms; second, Mr. H. B. Young; third, Mr. W. J. Grant. For six Mr. Leonard Brown, the only exhibitor, was awarded the first prize. For six varieties Parvi-Coronati, Miss F. W. Currey and Mr. H. B. Young were placed equal first; third, Mr. C. Dawson; fourth, Mr. C. Dawson and Messrs. Pope and Sons, equal. For twelve varieties Narcissi the first prize was awarded to Mr. A. J. Styles, Spalding; second, Mr. R. C. Bick, gardener to Walter Chamberlain, Esq., Harborne Hall, Harborne, Birmingham; third, Mr. W. B. Latham; and fourth, Mr. J. Mallender, Worksop. For six the first prize was given to Mr. C. R. Bick for remarkably fine examples; second, Mr. H. J. Stiles; and third, Mr. J. Mallender.

For six vases of Spanish Irises the first prize went to Mr. R. Sydenham, the only exhibitor, with bright examples. Daffodils in pots were very well represented, but the Polyanthus section was only of medium quality, the chief exhibitors being Messrs. Cryer, Isaac Cooke, Robert Sydenham, J. Sceaney, Harborne; and E. M. Sharp, Edgbaston. Tulips were exceedingly well shown, and for six pots of single flowers Messrs. R. Sydenham, A. Cryer, and J. Sceaney were the prizetakers in the order named. Fine examples of Lily of the Valley were in evidence, and the prizes fell respectively to Messrs. I. Cooke and A. Cryer; Cyclamens were also well shown by Mr. F. Impnoy, Northfield, and Mr. C. L. Bronson, Coleshill; Cinerarias were fairly well staged by Messrs. A. Cryer, I. Cooke, and Mr. Musten, gardener to H. F. Bird, Esq., Moseley; Lilium Harrisii made an attractive show by Messrs. I. Cooke and A. Cryer.

Table decorations formed a very attractive feature, Messrs. John Pope & Sons, I. Cooke, and Musten being the winners with elegant designs, composed of Daffodils and ornamental foliage. Groups of spring flowers were nicely shown by Messrs. A. Cryer, Musten, and Rev. J. Jacob. For a bouquet of Daffodils Messrs. Pope & Sons were to the fore with a most elegant example, and Mr. A. Cryer excelled himself with a somewhat similar arrangement. Bowls of cut Daffodils made a striking feature, the best coming from Mr. A. Cryer, W. J. Grant, and Miss Rosie Sydenham. For a group of cut Daffodils the Rev. J. Jacob, and Messrs. I. Cooke and Musten were the winners. For three jars of Polyanthus Narcissus Messrs. I. Cooke and E. M. Sharp were placed as named. For three pairs Daffodils Messrs. A. Cryer, I. Cooke, J. Sceaney, and E. M. Sharp were placed in order named. For a box of cut Daffodils Messrs. J. Manger & Sons, Guernsey, were awarded the first prize; Mr. J. T. White, Spalding, the second, and Mr. I. Cooke the third.

The Young Gardeners' Domain.

Forcing Peaches and Nectarines.

CONTINUING my remarks on the above subject, from page 274, I should like to emphasise the necessity for early disbudding. Nothing appears to me to be gained by allowing the development of useless shoots, which exhaust the food reserves. They should, therefore, be removed early, that those which remain may have all the support

possible to lay the foundation for the production of an abundance of bloom buds and fruit for the following season. Disbudding must therefore commence before the buds have expanded into leaf, subsequently removing those that remain at intervals of three or four days. If the tree has covered the space allotted to it, one shoot at the base and another at the apex of last season's growth will be sufficient. Overcrowding of the shoots should be avoided, so that when fully developed sun and air may have free access to all parts.

In numbers of cases many more fruits will be set than are required, and it will be necessary to thin them. First remove those that are not in a good position, continuing gradually with the worst fruits until only the desired number of the best placed and most promising remain; the last thinning should take place when the fruits are about the size of Walnuts. The crop of fruit which a tree can perfect depends on its health and vigour, and also on the variety. The Nectarine will bring to perfection more fruits than the Peach; careful forethought should therefore be given to the subject, so that each tree may be cropped according to its ability.

During the stoning period care should be taken that the trees do not receive any check, either by sudden fluctuations of the temperature or over-dryness at the roots. An equable temperature and a genial atmosphere must be maintained. Keep the foliage clean by forcibly syringing the trees on fine days with the hand pump or syringe, and examine the borders frequently to ascertain their condition, and whenever water is needed give sufficient to thoroughly moisten the whole to the drainage. When the fruits commence the final swelling the minimum night temperature should be 60°. Dispose the shoots evenly over the space at command, and secure them to the trellis in such a manner as to leave the fruits exposed to the light as much as possible.

When the fruits commence to ripen syringing should be discontinued, and a free circulation of air maintained both night and day. Fresh, pure air and full sun are important factors in the production of fruit of high quality and good colour. Examine the trees daily, and carefully remove fruit sufficiently ripe. When the crop is gathered the house must be freely ventilated, and the trees well washed occasionally to free them from red spider, which may have made its appearance. The old wood that has borne fruit, and any shoots not required, should be cut out to admit all the light possible, in order that the young wood may be thoroughly solidified and matured. If the roof-lights are movable they may be taken off with advantage when the leaves have fallen, or in the case of early forced trees when the wood is well ripened and the buds plump. If they cannot be removed the ventilators should be open continually, and the house kept as cool as possible.—S. P.

Fruit Forcing.

Vines.—*Early Houses.*—Vines started at the new year have the Grapes in an advanced stage for ripening; indeed, some are commencing to colour, and will need a circulation of warm rather dry air. It is imperative to keep the foliage clean and healthy for as long a period as possible. Where red spider has obtained a hold, prompt measures must be adopted for its destruction.

Houses of Ripe Grapes.—Early Vines that have ripened their crops require a circulation of air, and the temperature should fall to 60° at night. The soil must be kept moist, so as to keep the foliage in good condition. Moderate air moisture also is essential to prevent the foliage prematurely ripening, and it benefits rather than prejudices the keeping of the Grapes, provided the atmosphere is not stagnant. The Grapes are liable to lose colour with hanging; a slight shade will be beneficial in helping to keep colour, especially in Black Hamburgs and Madresfield Court. It is also desirable, where it can be practised without crowding the principal leaves, to allow a moderate extension of the laterals.

Muscats.—The Vines started in December to afford a supply of ripe fruit early in June are now beginning to colour. Muscat of Alexandria takes longer to colour than Muscat Hamburg and Madresfield Court. The Grapes of the former variety are liable to shrivel unless the Vines are well supplied with water and nourishment at the roots. When these are provided judiciously a much drier condition of the atmosphere may be allowed than is otherwise safe, and this is essential to good finish in Muscats. Directly the Grapes change colour give a thorough supply of water or liquid manure, following with a mulch of rather strawy material. As a safeguard against scorching, to which Muscat of Alexandria is subject, a slight shade should be provided, ventilating early, and increasing the air with the advancing sun heat, but allowing a high temperature by that means.

Muscats in flower set freely with a night temperature of 70°, 75° by

day, and 80° to 85°, or 90° with sun heat, always with a circulation of air. The points of the bunches should be kept well up to the light. When the cups of the flowers are being cast off it is advisable to rap the bunches lightly, better still to gently go over each with a camel's-hair brush, and follow soon afterwards, or when the caps are off, with another brush loaded with pollen taken from free-setting varieties, such as Alicante and Black Hamburgh. The influence of foreign pollen is far more potent, and secures finer berries than impregnation of a variety of Grape or other fruit with its own pollen, which is often inert.

Succession Houses.—Follow up thinning the bunches and berries, also tying, disbudding, stopping, and regulating the growths. Allow crops proportionate to the vigour of the Vines, and retain as much foliage as can have full exposure to light. Examine the borders at least once weekly, and when dry water freely, assisting those in full foliage and carrying heavy crops with tepid liquid manure and surface mulchings of rich material. In addition to this some fertiliser should be used.

Outside borders will not require any water unless there be a deficiency of moisture, then supply it liberally, and to encourage surface roots top-dress with some fertiliser, also mulch lightly if the border has not a good tilth of fine surface soil so as to retain moisture. Ventilate early, it causes accumulated moisture to disperse, gives texture to the foliage and firmness to the wood. Allow a high day temperature from sun heat, closing early, alike to push ahead the crop and to store the sun-warmed atmosphere. At night a rather low (60° to 65°) temperature is best, especially for Vines carrying heavy crops.

Late Houses.—Disbudding, also tying and stopping the growths, must be attended to as they become sufficiently advanced. The bright weather has given the foliage a remarkably healthy blue colour. Every advantage should be taken of sun heat to increase the ventilation early in the day, and of closing early in the afternoon, as a means of securing a long day's work, and of vigour and health in the Vines, dispensing with fire heat as much as possible, yet employing enough to keep the Vines in steady progress. Make a selection of the bunches that are to remain for the crop, large bunches, especially loose, being the worst for finish, and the medium-sized and compact the best. Crop lightly rather than heavily, and apportion the crop to the vigour and variety of Vine.

Late Hamburghs.—Disbud, tie down, and regulate the growths, not leaving more than can have space for the full expansion of the foliage. In stopping allow two at least, preferably four, joints of growth beyond the stem for show of fruit, and pinch the laterals below to one joint as made, but above the bunch allow them to extend, so as to insure an even covering of the space with foliage that can have full exposure; afterwards keep them pinched to one leaf as growth is made. Where the space is restricted closer stopping may be practised, not allowing the laterals to interfere with the principal leaves. Ventilate early and freely, so as to insure short-jointed wood and stout foliage. Avoid a saturated condition of the atmosphere, yet a genial state must be provided by syringing the borders, walls, and paths in the morning and at closing time, and secure proper moisture in the borders. A sprinkling of some approved fertiliser after each watering will be found advantageous.

The Kitchen Garden.

Beans.—Where Broad Beans are in demand till comparatively late in the season another two or three sowings may yet be made. Give the preference to the true broad podded section, notably the Green Windsor, and sow on rich cool ground. Broad Beans transplant readily, and if from any cause the early rows present a somewhat patchy appearance, one good row may be formed out of two poor ones by carefully lifting and replanting.

Runner Beans may now be sown in the warmer localities, but it is yet a little too early to sow seed in low-lying, damp positions. If the seed is sown in double drills 12 inches apart, and it is intended to use tall stakes to cross over the rows, these double rows may well be disposed 8 feet apart, with three rows of early Potatoes or Cauliflowers between them. Single lines of Beans that are to have 6 feet stakes may be disposed 6 feet apart, and have two rows of Potatoes, Cauliflowers, or Cabbages between them. Where it is intended to dispense with stakes altogether, the plants being kept closely topped market growers' fashion, the rows may be disposed 3 feet apart with one row of Potatoes or other quick maturing crop between. In each case avoid sowing too thickly, crowded Bean plants failing to bear pods so continuously as desirable. If extra early Runner Beans are wanted, raise the requisite number of plants singly in 3-inch or slightly larger pots under glass, hardening and planting out before they become much root-bound, and protecting with mats or canvas.

Celery Trenches.—According, as the ground is cleared of Broccoli, Borecole, Brussels Sprouts, and the like, good opportunities are offered for getting the Celery trenches prepared. Preparing the trenches is desirable for several reasons. If delayed till near planting time the ground is usually drier, harder, and much more difficult to get into a condition suitable for the reception of the plants. Early preparation also admits of the spaces between the trenches being most profitably cropped with Kidney Beans and Lettuces. Trenches to hold a single

row of plants may be 15 inches wide with 3 feet or 4 feet spaces between, while for double rows of plants a width of 18 inches is none too much, the spaces between being not less than 4 feet. The best of the top spit only should be thrown out of the trenches and disposed evenly on each side, as very deep trenches are a mistake. In the bottom of the trench dispose 6 inches of good, partially decayed, manure, mixing it somewhat with the soil by means of a fork.

Ridge Cucumbers.—If only a few plants of these are grown they may be raised singly in 3-inch pots in gentle heat, hardening and planting out on prepared ridges towards the end of May. Too often the plants are raised long before the proper time for planting out has arrived, with the consequence that a very bad start is made. Stunted yellow plants had better be thrown away and more seed be sown, the first fortnight in May being quite early enough to sow if little or no protection can be afforded the plants when turned out.

Vegetable Marrows.—Much that has been advanced concerning ridge Cucumbers also applies to Vegetable Marrows. If an early crop is desired a mild hotbed should be prepared at once, if not already done, on this disposing hand-lights, or better still frames. Plant directly the mound of loamy soil placed for the plants is warmed through, and keep them under cover till such time as they need much more space to ramble over. The bush varieties are usually the first to produce crops, and these are well adapted for frame culture, also for interspersing among the running varieties in the open.

Spinach.—During the hottest part of the summer Spinach is seldom obtainable. It can be had moderately late by sowing the Victoria or Longstanding on a cool well-enriched border, and a fairly good substitute may be found in the so-called New Zealand Spinach. A dozen or so plants of the latter will meet the demands of most establishments. Raise these now in heat, and early in June plant out of 3-inch pots on a sunny border singly 3 feet apart each way. They will rapidly attain to a great size, the short tops being gathered and cooked.

Spinach Beet.—In many gardens considerable difficulty is often experienced in providing abundance of Spinach during the winter and early spring months. A substitute is available in the form of large Spinach-like leaves produced by Spinach Beet. The seed of this should be sown at once in drills 12 inches apart, thinning the plants to about 6 inches asunder. Frosts rarely if ever destroy this Beet, and the roots produce a profusion of leaves which good cooks can render fit for the table, serving similar to true Spinach.

THE BEE-KEEPER.

The Weather.

THREE successive bright sunny days, with a shade temperature ranging from 70° to 80°, have had a beneficial effect on the bees. Strong colonies have increased rapidly, and stocks that were considered weak have now several frames well filled with brood. The effect on vegetation is most marked. A week ago the pastures were brown and the trees bare, and with the exception of the early spring flowers few blossoms were visible; but now all this is changed, the pastures are green, but studded with thousands of flower; Plums, Almonds, Gooseberries, and Currants are wreathed with their fast-opening blossoms, and in a few days there will be a wealth of bloom on the Apples and Pears. Already, however, there is a change in the weather, the temperature is lower and rain threatens; a few warm showers would do a great amount of good.

Bee-keepers must be on the alert and not allow their bees to suffer from lack of stores. Pollen has been carried in freely; and breeding has been going on a rapid rate; but should dull weather ensue for a few days breeding will cease, as the queen will discontinue laying if the food supply is restricted. It is false economy to leave the bees to chance at this season and failure is much more likely to take place after a short spell of hot weather than if the weather had remained dull and cold. Feeding should be continued as advised in previous notes, and the bees must not be disturbed more than necessary. We still continue open air feeding, and find it a success. Although the weather may be dull it is not often at this season that the temperature is so low during the middle of the day but that some of the workers are able to leave their hive. If they have been regularly fed in the open they at once go to the feeders and take the warm syrup that has been provided for them.

Spring Dwindling.

In the best managed apiaries spring dwindling will sometimes take place. But it is the bee-keepers who leave their bees to take their chance who suffer most. It will arise from a variety of causes. Dampness in the hives, insufficient coverings, shortness of stores, and late feeding the previous autumn will cause it. The cure is a warm dry hive; the bees should be restricted to just as many combs as they can well cover. This is done by drawing the division board close up

to the frames, and if it does not fit closely to the sides and bottom of the hive the space at the back may be filled with any old coverings so as to keep the bees as warm as possible.

A stock of this description should always be fed with a slow feeder; there will then be no escape of heat from the hive. An extra frame may be given as required, and it is surprising how rapidly a weak stock will improve if worked on the above lines. Instead of the bees dropping from the cluster through weakness, to be afterwards found on the floor board dead, they become lively, and will work freely as the weather becomes warmer.

Many bee-keepers cannot understand the reason why some stocks are so much better than others at this season. Such, however, we find is always the case. All may have been well supplied with syrup the previous autumn and treated exactly the same. But the following spring it will be found on examination that some are much better than others, although spring dwindling has not taken place. This will also arise from a variety of causes. The age of the queen, and the time she stopped depositing eggs the previous autumn, are the chief causes. If the queen stopped laying early many of the bees, being old, would die off, and there would not be young bees to take their place.—AN ENGLISH BEE-KEEPER.

Trade Catalogues Received.

Barr & Sons, King Street, Covent Garden.—*Daffodils*.
Kelway & Son, Langport.—*Wholesale Plant Catalogue*.
W. Paul and Son, Waltham Cross.—*New Roses*.
T. S. Ware, Ltd., Feltham.—*Hardy Plants*.

All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Newly Planted Vines (*Inquirer*).—The canes planted this spring will indicate their taking to the soil by growing freely, and require ventilation early in the day, as the value of growth is dependent more on its sturdiness and solidification than on its length and sappiness. Encourage laterals rather than an elongation of the cane, but let that extend and retain all the growth that can have exposure to light. That is desirable where the Vines are weakly, but if they are vigorous it is a better plan to pinch the laterals at the first joint, and to one leaf of subsequent growth, stopping the canes at 9 to 10 feet, and allow the uppermost to grow a few joints, and then keep all closely pinched. If the cane produces growths cut away the worst. Supernumeraries intended for next year's fruiting should have the laterals pinched at the first leaf, afterwards allowing them to make a few joints of growth if weak, otherwise pinching to one leaf, stopping the cane at 8 or 9 feet of growth, taking every possible care of the leaves on the cane, not allowing them to be interfered with in any way by the laterals. Keep the soil moist, but not very wet, closing early, with plenty of atmospheric moisture.

Beet Near the Roots of Young Fruit Trees (*C. B. S.*).—We do not recommend Beet to be sown over the roots of young fruit trees, but advise keeping the ground free from weeds, which are often as bad or worse than a useful crop. Mulch outwards from the stem to the extent of the roots, or a little more, with about an inch thickness of rather short and not quite fresh manure. This will encourage the roots to spread near the surface, and secure greater uniformity of moisture in the soil by preventing evaporation, and instead of taking from the nutriment would add to that of the soil. Beet over the roots would abstract considerable nutrition from the soil, and the trees be prejudiced correspondingly.

Elæocarpus serratus (*Youngster*).—This plant is rarely seen, notwithstanding its beauty. According to the "Vegetable Kingdom" "the Elæocarpæ furnish a few plants to which a slight degree of interest is attached. Those round, carved-looking and rugged-furrowed, bony-like articles, which are used as necklaces and bracelets, and sometimes mounted in gold, are the fruit of the Olive Nuts (*Elæocarpus*) deprived of their fleshy parts. The fruits of some of the species are used in Eastern curries, and also pickled, while some are eaten raw, such as those of *E. serratus*, which the inhabitants of Ceylon preserve in brine before they are ripe, and eat with a little oil to give them a flavour. Rumphius says these fruits are good to eat, but the use of them is rather adapted for killing time than for any nourishment that can be obtained from them."

Ixoras (*R. T. P.*).—These plants succeed in a compost of two-thirds sandy fibrous peat torn in pieces by the hand, and one-third fibrous loam from decayed turves, adding about one-sixth part of silver sand and charcoal in pieces from the size of a hazel nut down to that of a pea, the whole being well mixed. The compost should be made rather fine, but not sifted. Good drainage is essential. Their proper time of rest is winter, during which they should be kept dry, but not so much so as to cause the foliage to flag. From September to February the temperature may be 60° at night, and from 65° to 70° by day, 55° at night in severe weather will not be too low. From February onwards the temperature should be slightly increased, so as to have it 65° at nights by May, and from 70° to 75° by day without sun, and from 80° to 90° with sun and abundance of air. These temperatures may be continued until September, when they should be allowed to decline.

Vine Leaves Mottled (*Gar*).—The leaves have the appearance of being infested by some fungus, but we cannot discover any mycelial hyphae in the tissues, and, of course, no outgrowths. It is not unusual for the leaves to have a somewhat yellowish and mottled appearance after recently planting, they being relatively small, somewhat thin in tissue, and not firm in texture. This only endures for a time, as when the roots work freely in the border the foliage gradually improves. Sometimes the roots, where turf is used, are preyed upon by wireworms and other pests, the foliage suffering in consequence. We advise a dressing to the border of a mixture of bone superphosphate three parts, sulphate of potash two parts, and sulphate of magnesia one part, mixed, using 4 ozs. per square yard, and pointing in lightly. To aid the development of the chlorophyll a dressing of soot, a good handful per square yard, may be used with advantage, or about half an ounce per square yard of finely powdered nitrate of soda. The soil should be kept moist, but not overwatered.

Bark of Beech Tree (*Somerset*).—The matter on the bark of the Beech tree is not caused by a fungus, but is the substance secreted by the Beech-bark scale insect, *Crytococcus fagi*, which fixes itself to the bark and pushes its beak into the living tissues, abstracting the sap of the tree, and the tree suffers in consequence, many left to their fate succumbing, even when of very large size, to the assaults of the pest. The tree should be dressed with a petroleum emulsion made by dissolving 1½ lb. of softsoap in a gallon of water over a gentle fire, and when boiling, the softsoap being dissolved, remove from the fire and add half a pint of paraffin oil, stirring briskly until thoroughly amalgamated, and for use dilute to 6½ gallons with hot water. Apply with a brush to the bark while at a temperature of 130° to 140°, using a rather stiff, or half-worn, clean paint brush, rubbing well into the cracks and crevices and dressing every part from the roots upwards to the full extent of the infestation, not leaving any part of the roots running on the surface of the ground undressed. From the early part of August to the middle of September look carefully over the tree, and if any white flocculence appear on the bark dress the parts with the solution. Similar attention should be given in the following spring, and then the pest will be subdued, though it is well to keep an eye on the tree and promptly apply the solution whenever the white appears.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not

more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. W.).—The Rose is one of the Lawrenceana (Miniature China) varieties, probably Gloire des Polyanthes, but the flower had fallen to pieces on arrival. (O. P.).—1, Vanda snavis; 2, Læliopsis domingensis; 3, Dendrobium fimbriatum oculatum. (B. D.).—1, Pteris umbrosa; 2, Adiantum capillus Veneris; 3, Asplenium bulbiferum; 4, Nephrolepis davallioides furcans; 5, Pteris cretica; 6, Selaginella Kraussiana. (S. E.).—1, Ribes aureum; 2, Viburnum Opulus; 3, Forsythia viridissima; 4, Lonicera hirsuta; 5, Prunus (Cerasus) Padus, the Bird Cherry; 6, Amelanchier Botryapium, the Snowy Mespilus. (L. D. M.).—1, Aubrietia purpurea; 2, A. Leitchlini; 3, Iberis correæfolia; 4, Doronicum plantagineum; 5, Phlox setacea. (O. V.).—Prunus (Cerasus) Padus, the Bird Cherry.

What is being done at Wye?

WE will fairly own up to our ignorance. If anyone had asked us two years ago of Wye our thoughts would have turned to placid meadows and more placid Herefords grazing therein. We know better now. We have localised Wye, and we have learned something of the work carried on there from an article by Mr. Willan in a recent number of the "Agricultural Economist." Kent has always been counted the garden of England, and therefore it is only fitting that in Kent should be established a training school for the future agriculturist, not only of that but of adjacent and other counties. No one hesitates now to urge a more scientific training for the young farmer, he must be put on a par with our professional men, for he wants, before he can make a living, a thorough knowledge of the ins and outs of his work. It is not book work alone that is learned here. A large farm gives the practical side. We find 130 acres of arable, with 120 of pasture land on the river Stour. Light soil, but responsive to generous treatment. No make-shift implements, no second-rate stock. Let us just see how things work out. Six-course system, so the plots are of eighteen acres in extent, with a twelve acre Lucerne field, Swedes and white Turnips, Barley, Mangolds, Cabbage and Potatoes, Wheat seeds, Oats, just what these young men will find on nineteen out of twenty-one farms.

Milk is a great feature of the farm, and we are glad of it, as in the better development of the milk trade depends many a farmer's well doing. The producers of this milk are Shorthorns of good milking strain, for mind you, kind reader, there are Shorthorns who do not fill the pail. We are not surprised to hear sheep do well. Romney Marsh is the variety. Such soil as is here described is the very best type for keeping sheep alive and improving them rapidly. Some districts are so essentially non-sheep growing that a trial results only in loss and constant disappointment. Berkshire and Middle White supply the bacon, and Shires the motive power. Of course the little industries are not neglected, and we are glad to see so much attention paid to the fowl yard. There is so much mismanagement among fowls, their purpose and their wants are often so badly understood, that they prove a loss instead of being a distinct gain. The same applies to the dairy school; it is no use having good milk to be ill managed, and why a lad properly trained should not make a deft dairyman we do not know. They have got the chance of an insight into all the mysteries. Wye would not be in Kent if Hops and fruit trees were left out and space is devoted to their care and culture.

To give a full list of the governing body, of the professors and the general staff, would take up more room than our editor would allow. Suffice it to say they are picked men. Many of the names have (shall we say) wide-world fame. This school or college was founded in 1894 by the Kent and Surrey Councils, and they contribute jointly £3000 per annum. The Board of Agriculture, too, comes in for a share of the expense. The study of chemistry is a natural outcome of any teaching bearing on agriculture or horticulture. Thus we find a laboratory specially prepared for the students' use, and also a biological laboratory for botanical and zoological experiment.

That this school has caught on is amply proved we think by the fact that the present accommodation is not enough; it has to be enlarged. This is a most satisfactory state of things, especially as we think the boarding fees just a trifle high. We see however, exceptions are made in favour of farmers' sons who show just cause for not being able to pay on the higher scale, and there

are also certain scholarships open to Kentish and Surrey youths. There is also a scale of fees for those who reside at home or with friends, but who attend the classes; day pupils we might call them. These fees are extremely moderate, and they make us rather wonder why, if the actual teaching can be afforded at so cheap a rate, the board and lodgings should be so high? Surely never were provisions so cheap as at the present, and the larger the party the more easily catered for. The full course is for two years. The students must be over sixteen years of age, and able to pass a test examination to show they have received a fair middle-class education, such as would be a lad for Cambridge or Oxford local senior examinations.

For the first year the student is expected to devote himself to such subjects as bear on soil, subsoil, rotation of crops, manures, implements, drawing and building construction, surveying, chemistry, botany, zoology, geology, physics, and mechanics. We think an unbiased reader will say there cannot be much time wasted if all these subjects are thoroughly gone into. Then the second year leads on to the management of live stock, dairy work, farm hygiene and management, engineering, surveying, levelling, drawing and building construction, agricultural chemistry, agricultural botany, entomology, veterinary science, estate management, law, forestry, poultry and bee keeping, Hop and fruit growing.

Now we hardly suppose it possible, or even desirable, that a youth should take up all these subjects. He will be guided by circumstances, and devote himself more especially to those branches for which he has the greatest aptitude; at any rate, he gets a chance of developing what talents he has. He comes, or should do, straight from school, where work has been done in an orderly manner, and he takes up new studies before he has lost the powers of application.

We know by ourselves how soon we get out of gear, as it were, and we have always advocated going straight from school to the training grounds for the life work. Desultory habits are quickly acquired, and not so quickly got rid of, and indeed a lad of sixteen or seventeen has not much time to lose. The sooner he has gone through his college course the sooner is he fitted to earn a little towards his own living. We think these studies are essentially fitted for farm-bred boys. They get to know the why and the wherefore of processes they have seen carried on at home, and if they have anything at all about them will soon be wanting to experimentalise on the paternal acres, and it is these lads who will make the future farmers. For lads other than those bred on farms we fancy the two years will be hardly enough. They will probably want rather a longer course, or an apprenticeship on a large mixed occupation under a master in the art.

Work on the Home Farm.

The wind and rain of Easter have been followed by a week of bright sunshine, with abnormal day temperature and fairly warm nights. There have been two frosts, but only slight ones; the result is a rapid growth of everything sown. Farmers agree that they never knew Barleys come up so quickly from the drills as have those lately sown. The warmth is having a splendid effect on grass and seeds, and if it were only possible to give pastures a short period of rest they might soon be really good. The improved prospect has a very hardening effect on prices of fat stock, as farmers are not too fully stocked, having perforce thinned their flocks and herds during the winter, and they are now anything but willing sellers. With a continuance of genial weather we anticipate somewhat of a boom in the stock markets.

We fear that there is no chance of a similar boom in grain. Last week's corn averages show an increase over the averages of twelve months ago of 1s. 4d. per quarter in Wheat and 4d. per quarter in Barley, whilst there is a decline of 2d. per quarter in Oats. Since last April we have had on our hands one of the biggest wars in our history, and an enormous drain on our stores of foodstuffs. Apparently the orders have gone to other countries, for our markets have been practically undisturbed, and it seems now quite hopeless for any miracle to occur that can give the British farmer any material help. Here we see the coal owners practically coining money as the result of combination at a pinch, but farmers have made no attempt to bring about a similar benefit to themselves through the scarcity of Potatoes. A splendid opportunity has here been lost simply from lack of cohesion. When will farmers cease to act individually, and really combine for their mutual benefit?

Mangolds being all sown, we are now preparing for Turnips; the

land is in good trim, and manures must be got ready for use when required. Superphosphate is the sheet anchor for both Turnips and Swedes, and if a good dressing of spit manure can be provided, phosphate is the only artificial required. Without manure for Swedes we should use 2 cwt. steamed bonemeal at 95 per cent. and 3 cwt. superphosphate per acre. Also 1 cwt. nitrate of soda after singling if the land be in poor condition.

Farmers are talking of growing Rape partly instead of Turnips on account of the probable difficulty of getting Turnips hoed and singled. This idea may be carried too far, and we ourselves would make great efforts to avoid such a disaster as the loss of the Turnip crop would involve. We should have thought that the want of roots had been sufficiently felt this season without willingly undergoing a repetition of it through lack of energy under difficulties. We remember a widow lady (a farmer) during a strike in the early seventies going out to hoe Turnips day by day, and surely present day farmers will not give up growing roots whilst such a thing as a singling machine is possible of invention and horses are not extinct.

THE AMERICAN WHEAT CROP.—According to the April report of the Department of Agriculture, the average conditions of the Wheat crop on the first day of the month was 82.1 per cent. of a full crop condition, as compared with 77.9 for last April, and 86.7 for April, 1898. In most recent years it has been the spring crop which, for its part, has done best, not only because it has yielded better than the winter division, but also because its acreage has shown the greater increase. This season, however, the lateness of sowing may possibly tell against the extent of the spring crop.

THE INDIAN WHEAT CROP.—A very disappointing account of the Wheat crop of India is given in the Second General Memorandum on it issued by the Indian Statistical Department. The only province in which an average yield is expected is Bengal, which is one of the comparatively small Wheat-growing provinces. In the greatest, the Punjab, where the area sown is 29 per cent. less than that of last year, only about half an average yield is expected on land not irrigated, and no more than 62 per cent of an average on irrigated land. In the North-western Provinces of Oudh, which stand next to the Punjab in area of Wheat, the outlook is not so bad, 75 to 80 per cent. of an average being anticipated. In the other provinces, however, the outlook is even worse than it is in the Punjab, the area being greatly reduced and the yield expected very small.—("Agricultural Gazette.")

ASPATRIA AGRICULTURAL COLLEGE.—The annual prize distribution at this institution, which was unavoidably postponed at Christmas, took place on Wednesday last week at the college, on the conclusion of a successful winter session, during which the college has been full up—numbering over forty students in residence. Principal and Mrs. Smith Hill entertained the staff and students to supper, and at its conclusion the college prizes and diplomas were handed to the successful students by Miss Todd. The external honours gained during the past year by Aspatria students are to be presented at the next public distribution, which is a well-known established feature of the college, when it is hoped that Mr. J. Bowen-Jones, J.P., member of the Council of the Royal, and chairman of the Shropshire C.C., will make the presentation.

AN LL.D. ON FEMALE FARM LABOURERS.—Extremes meet. While the Countess of Warwick is heading a crusade for getting women of culture to take up "lady crofting" as an intellectual and refined pursuit, and not as "mere turmit-hoers," Mr. Ferguson, LL.D., of Kinmundy, is equally anxious to get women "banished from the field" of agricultural labour altogether. Speaking at an agricultural meeting in Aberdeen last week Dr. Ferguson said, "One interesting thing connected with machinery was the completeness with which it had banished female work from the harvest field, and he thought that was a very good thing in itself. He should like to see all female labour banished from the harvest field." Apparently this LL.D. thinks that, although "corn rigs and Barley rigs are bonnie," yet they are not a suitable scene for female labour. The doctor gives no reason for considering the healthful and pleasant work on the "corn rigs" unsuitable for women. Potato harvesting would come under the same ban from the LL.D. of Kinmundy, and, as a matter of course, if the harvest field be an unsuitable scene for the labour of women, the cleaning and seeding of the land would be equally unsuitable as women's work. No doubt Dr. Ferguson has in his time delivered numerous speeches, in which he deplored the evils of rural depopulation and the miseries caused by overcrowding in the great cities, where women are forced through sheer necessity to work long hours every day under conditions which are a terribly sad contrast to the healthful and pleasant conditions of work in the harvest field. But did it never strike the learned doctor that the evils of rural depopulation would be tremendously intensified if female labour were to be banished from the field of agricultural work? Or does the laird of Kinmundy think that every woman ought to aim at being an LL.A., just as he is an LL.D. Far be it from us, however, to attempt to chop logic with a doctor of laws and logic of the calibre of "Kinmundy."—"North British Agriculturist.")

In the preceding statement the number of blooms staged in the classes set apart for three or more blooms of any one variety is not included.

As in the previous analysis, the positions given the different Show and Fancy Dahlias in the accompanying tables are dependent upon the average number of times each variety was staged at the last eight exhibitions of the N.D.S.

That reliable variety Mrs. Gladstone still retains the premier place on the list of Show Dahlias, a position it has now held for fourteen successive years. At one time, John Walker, the only pure white Dahlia in the table, and at another, R. T. Rawlings, the best yellow, threatened to displace it, but this refined pale blush variety by its more consistent records has always managed to maintain a decided lead over all other competitors. Next comes that dependable purple variety, William Rawlings, which is rather older than either of the three sorts above referred to. Neither of these four leading Show Dahlias was, however, quite up to its usual form last year; while Harry Keith, Mrs. Langtry, and a few other good sorts were even

more indifferently represented. Indeed, among the first twelve Shows in the table only J. T. West and William Powell were more frequently staged than usual. On the other hand, most of the varieties in the second dozen were in advance of their average records.

Of the newer Show varieties, those five or less years old, Dr. Keynes, sent out in 1896, occupies the best position at No. 16, having risen ten places since the previous analysis was issued. Next, at No. 22, we come to Shotesham Hero, distributed in 1895, which has also improved its position since last year. Florence Tranter, an 1896 variety, follows at No. 26; Chieftain, distributed in 1894, rises from No. 30 to No. 28; while Warrior, sent out in the same year, is still to be found at No. 29. Muriel Hobbs (1898) on its first appearance on the list takes its place at No. 44. The last of the seven newer sorts, Mrs. Every, although introduced in 1896, only just manages to creep in at the bottom of the table.

At the head of the Fancies we still find that marvellous Dahlia, Rev. J. B. M. Camm. I call it marvellous because, although it has now been in cultivation for more than a quarter of a century, no

SHOW DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown.	No. of Times Shown in 1899 in True Relative Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	31.3	25	Mrs. Gladstone	1884	Hurst	Pale blush
2	25.4	20	R. T. Rawlings	1886	Rawlings	Clear yellow
3	23.5	19	John Walker	1892	Walker	White
4	22.4	20	William Rawlings	1881	Rawlings	Crimson purple
5	22.1	20	Colonist	1887	Keynes	Chocolate and fawn
6	21.0	20	Duchess of York	1894	Keynes	Lemon, edged salmon pink
7	20.9	24	J. T. West	1887	Rawlings	Yellow and purple
8	20.1	9	Harry Keith	1886	Koynes	Rosy purple
9	19.9	10	Mrs. Langtry	1885	Keynes	Cream and crimson
10	17.4	14	James Cocker	1871	Keynes	Purple
11	17.2	15	Arthur Rawlings	1892	West	Deep crimson
12	16.8	21	William Powell	1892	West	Primrose yellow
13	16.7	20	Duke of Fife	1890	Keynes	Rich cardinal
14	16.0	17	Maud Fellowes	1889	Fellowes	Pale pink, shaded purple
15	15.7	19	John Hickling	1890	Keynes	Clear bright yellow
16	14.5	17	Dr. Keynes	1896	Keynes	Rich buff
17	14.4	19	Mrs. W. Slack	1886	Keynes	Blush white and purple
18	14.3	11	Henry Walton	1873	Koynes	Pale yellow and scarlet
19	14.1	16	Harrison Weir	1883	Rawlings	Yellow
20	13.6	16	Miss Cannell	1881	Eckford	Cream and crimson
21	13.4	6	Ethel Britton	1880	Koynes	White and purple
22	13.3	15	Shotesham Hero	1895	Fellowes	White, tipped and shaded rose
23	12.6	14	Arthur Ocock	1892	Rawlings	Reddish orange
23	12.6	7	Shirley Hibberd	1881	Rawlings	Dark crimson
23	12.6	6	Willie Garratt	1887	Garrett	Bright cardinal
26	12.0	10	Florence Tranter	1896	Tranter	Blush white, edged rosy purple
27	11.4	5	T. J. Saltmarsh	1885	Rawlings	Yellow and chestnut
28	11.3	15	Chieftain	1894	Keynes	Purplish lilac
29	11.0	12	Warrior	1894	Keynes	Scarlet
30	10.0	20	Goldfinder	1881	Fellowes	Yellow and red
31	9.9	9	Prince of Denmark	1881	Fellowes	Dark maroon
32	9.4	11	Victor	1887	Keynes	Dark maroon
33	9.0	7	Majestic	1890	Keynes	White, edged purple
34	8.5	9	George Rawlings	1882	Rawlings	Dark maroon
34	8.5	7	Hon. Mrs. P. Wyndham	1881	Keynes	Pale yellow and rose
36	8.3	9	Virginale	1893	Keynes	Blush white, edged pink
37	8.1	7	Mrs. D. Saunders	1888	Rawlings	Pale, edged rose
38	8.0	2	Perfection	1889	Fellowes	Orange buff
39	7.9	4	Glowworm	1889	Turner	Bright orange scarlet
40	7.8	10	Mr. Glasscock	1886	Rawlings	Purple
40	7.8	10	Mrs. Morgan	1893	Fellowes	Pale ground, tinted rosy purple
42	7.6	10	Crimson King	1887	Keynes	Deep crimson scarlet
43	7.1	6	Alice Emily	1890	Keynes	Buff yellow
44	*7.0	7	Muriel Hobbs	1898	Hobbs	Yellow
45	6.6	1	William Keith	1888	West	Dark plum
46	6.4	5	Burgundy	1877	Turner	Dark puce
47	5.9	6	Earl of Ravensworth	1883	Harkness	Lilac
47	5.9	5	Prince Bismarck	1879	Fellowes	Puce
47	5.9	1	Queen of the Belgians	1887	Rawlings	Cream and pink
50	5.0	6	Mrs. Every	1896	Keynes	White, edged lilac

* A new variety, the position of which is dependent on its record for the 1899 show only.

other variety in this section can come up to it—can show as good an average record. In fact, only three years ago it was more numerous than any other Show or Fancy Dahlia in the exhibition, except Mrs. Gladstone and R. T. Rawlings. Duchess of Albany is another very reliable variety, and at the last two shows was rather more frequently staged than the leading flower. Mrs. Saunders, which some years ago was at the head of the list, although less largely shown than formerly, still retains its place at No. 3. The principal varieties which were to be met with last year more frequently than usual were Duchess of Albany, Dorothy, and Peacock; whereas Rev. J. B. M. Camm, Matthew Campbell, and T. W. Girdlestone were below their average form.

Of the three comparatively new Fancies in the table, Goldsmith, sent out in 1895, takes the lead at No. 8, having risen five places since the previous exhibition. Next comes Emin Pasha, distributed in 1894, at No. 12, followed by S. Mortimer of the same year at No. 13.

Turning our thoughts to those charming miniature Show and Fancy Dahlias, the Pompons, it will at once be realised that the changes here are more rapid, or rather less sluggish, than in the case of the two sections we have just dealt with. Consequently, a shorter average will better suit their requirements. Taking the mean records for the last four shows the varieties arrange themselves as follows. Those marked with an asterisk were sent out in 1898 or subsequently:—Bacchus, Tommy Keith, Nerissa, Emily Hopper, Phoebe, Captain Boyton, G. Brinckman, Whisper, Douglas, Dr. Jim, Sunny Daybreak, Arthur West, Distinction*, Eurydice, E. F. Jungker, Lilian, Demon*, and Snowflake*.

Up to the present time George Brinckman has stood in the forefront of the few good white Pompons that we have, while the latest candidate for honours is Snowflake, a new variety of much merit. Emily Hopper, although first distributed in 1874, still takes precedence of all the yellows; the best orange coloured variety being Phoebe, and the best pale yellow E. F. Jungker. Coming to the different shades of red, we find Bacchus, the leading flower in this section, at the head of the scarlets, Arthur West at the head of the crimsons, while Nerissa stands alone as the representative of the rose-coloured Pompons. Among maroons stands as leader Captain Boyton, rather closely followed by Douglas. Of the newer selfs may be mentioned Distinction and Demon as promising well in their respective shades of crimson.

In order to give some idea of the changes and improvements that have taken place in recent years in the Cactus section, I have

arranged in the following list the different varieties according to the number of times they were staged at the last exhibition of the National Dahlia Society; and for comparison their records for one or both of the two previous shows whenever they were represented five or more times:—

CACTUS DAHLIAS.

	1899	1898	1897	Colour.
Britannia, 1898	26	14	—	salmon pink and apricot
C. Woodbridge, 1897	25	18	—	crimson
Starfish, 1897	25	34	7	orange scarlet
Keynes' White, 1898	23	19	—	ivory white
Mary Service, 1898	23	21	—	russet yellow and heliotrope
Night, 1898	18	18	—	dark crimson
Countess of Lonsdale, 1899	17	—	—	salmon and apricot
Magnificent, 1899	17	—	—	salmon pink and apricot
Lady Penzance, 1894... ..	14	26	24	pure yellow
Lucius, 1899	13	—	—	deep orange
Alfred Vasey, 1898	11	8	—	reddish amber
Cinderella, 1897	11	18	—	purple
Fusilier, 1896	11	24	25	coral red
Stella, 1898	9	—	—	bright crimson
Viscountess Sherbrook, 1899	9	—	—	reddish terra cotta
Capstan, 1898	8	—	—	brick red
Laverstock Beauty, 1898 ...	8	—	—	soft red
Arachne, 1898	7	15	—	white, edged crimson
Island Queen, 1898	7	11	—	lilac mauve
Mrs. J. Goddard, 1898	7	—	—	crimson scarlet
Ebony, 1899	6	—	—	deep ebony
Eileen Palliser, 1898... ..	6	—	—	yellow
Mrs. Peart, 1893	6	8	9	creamy white
Exquisite, 1899	5	—	—	reddish cinnamon
Mrs. Wilson Noble, 1896 ...	5	21	17	pinkish salmon
Regulus, 1898	5	6	—	rich crimson

For the sake of our analysis if for no other reason, it is to be hoped that at all events some of the sorts mentioned in this list have come to stay. Hitherto the reputations of the Cactus Dahlias, which have been from time to time sent out in such rapid succession, have been extremely fleeting. For instance, it will be noticed that only Starfish, Lady Penzance, Fusilier, Mrs. Peart, and Mrs. Wilson Noble were sufficiently represented at the last three shows to entitle their records to appear under each of the three years. Moreover, of the fifteen varieties for which records are given for the last two years, more than half that number—Starfish, Lady Penzance, Cinderella, Fusilier, Arachne, Island Queen, Mrs. Peart, Mrs. Wilson Noble, and Regulus, although a year older at the time, were not as frequently exhibited in 1899 as in 1898, showing that they were rather losing than gaining ground in general estimation.

FANCY DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown.	No. of Times Shown in 1899 in True Relative Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	20.9	18	Rev. J. B. M. Camm	1873	Keynes	Yellow and red
2	18.8	20	Duchess of Albany.....	1884	Turner	Orange and crimson
3	16.9	17	Mrs. Saunders.....	1872	Turner	Yellow and white
4	16.3	16	Mrs. John Downie	1889	Turner	Orange and scarlet
5	13.3	8	Matthew Campbell.....	1889	Keynes	Buff and crimson
6	12.9	11	Frank Pearce	1886	Rawlings	Rose, striped crimson
7	12.5	15	Dorothy	1888	Keynes ..	Fawn and maroon
8	12.0	16	Goldsmith	1895	Keynes	Yellow, striped crimson
9	11.7	9	T. W. Girdlestone	1890	Keynes	Lilac and maroon
10	10.0	8	Buffalo Bill	1890	Keynes	Buff, striped vermilion
11	9.6	12	Peacock	1877	Turner	Maroon and white
12	9.5	10	Emin Pasha	1894	Keynes	Yellow, striped crimson
13	8.4	11	S. Mortimer.....	1894	Mortimer	Rose, striped crimson
14	8.3	8	Rebecca	1883	Keynes	Lilac and crimson
15	7.4	7	Comedian.....	1892	Keynes	Orange and crimson
16	6.4	7	Dandy	1891	Keynes	Orange, striped crimson
17	5.9	2	Henry Eckford	1886	Rawlings	Yellow and red
18	5.5	11	Hercules	1877	Keynes	Yellow and crimson
19	5.4	5	Dazzler	1893	Keynes	Yellow, striped scarlet

A good white Cactus was at last found in Keynes' White, but even this is likely in the coming season to be superseded by a still finer flower of the same type—Green's White. Several yellows have made their appearance in recent years, but none has hitherto been found to equal Lady Penzance as an exhibition flower. But this old favourite, for is it not six years old? will I fully expect have to give place shortly to that paler but altogether superior flower of the same colour—Mrs. J. J. Crowe. Among crimsons Charles Woodbridge will, I think, be found hard to beat. At present Starfish, although not such a good type of flower as the variety last named, holds its own as the best scarlet. As regards the dark Cactus Dahlias, only three years ago Matchless (up to that time matchless in its shade of colour, and also matchless in habit), was to be seen in every stand, but has now been totally eclipsed by Night. Among the new type of Cactus, those with incurved florets, the orange Lucius stands high, if not at the top of these particular varieties. Coming now to those less pronounced tints which seem to defy all classification, so delightfully are the different shades of colour blended in them, we find some of the best Cactus Dahlias, if we consider together the form of flower and the habit of growth, that have yet been raised. I refer more particularly to such superb sorts as Britannia, the leading flower on the list, Mary Service, and Magnificent.

The most difficult section to arrange satisfactorily is the singles, on account of the limited competition in the classes devoted to these easily grown and dainty flowers at the exhibitions. This is, I think, much to be regretted, as they add greatly to the attraction of any show, forming as they do such a marked contrast to the double flowers in the other sections. Perhaps now that handsome silver medals (the new Girdlestone Memorial medals) are to be in future offered at our National Dahlia Shows in addition to the first prizes in several classes devoted specially to the single flowered Dahlias, more nurserymen and amateurs may be induced to compete in those classes.

In the following select list the varieties—except the newer ones, those sent out in 1897 or subsequently, which are marked with an asterisk—are arranged according to their average records for the last three shows. Polly Eccles,* Demon, Miss Roberts, Victoria, Jack Sheppard, Naomi Tighe,* Northern Star, W. C. Harvey, Aurora, Beauty's Eye, Donna Casilda,* Duchess of Marlborough,* Phyllis, Formosa, Miss Glasscock, Folly,* and The Bride.

Polly Eccles, in the opinion of the raiser, the late Mr. T. W. Girdlestone, "the best type both as to habit and form among single Dahlias," deservedly heads the list. This is followed by another of Mr. Girdlestone's flowers, Demon, the best maroon variety, and next comes Miss Roberts, the best yellow. The variety last named, although distributed twelve years ago, still stands unrivalled in its colour. A really good white, a really good crimson, and a really good scarlet are still wanted; at present the best in their respective tints are The Bride, Rosebank Cardinal, and Formosa. Of the varieties named in the list Polly Eccles, Demon, Jack Sheppard, Naomi Tighe, Donna Casilda, Phyllis, and Folly, or nearly half the number, were raised by Mr. Girdlestone.—E. M., *Berkhamsted*.

Reminiscences of An Old Florist.—No. 7.

In thinking over the matters which most deeply interested me in horticulture during the sixties and seventies there are some few facts which stand out with great prominence. First the opening of the Royal Horticultural Society's Gardens at South Kensington, which seemed to begin with such great promise, but which proved so disastrous that at one time the Society looked as if it would never survive it. Next, the Grand International Exhibition in 1866, probably the finest exhibition ever seen, but which owing to the capriciousness of our weather promised to be an absolute failure, and would indeed have

proved to be so had it not been for the courage of the few individuals who turned the expected failure into a grand success. Then there were others which, while they affected horticulture more or less, affected me personally very much.

I do not exactly recollect whether it was at the opening of the South Kensington Gardens, or somewhere about that time, that the editors of the *Journal of Horticulture* were looking out for some one to undertake the florist flower department of their Journal; my good friend, Mr. Standish, said to the late Dr. Hogg, "Surely you could have no more suitable person than the correspondent who signs himself 'D., Deal.'" He brought us together, we talked the matter over, and that was the beginning of our close and intimate friendship. During my intercourse with Dr. Hogg I was struck by his wide and extensive knowledge of everything connected with horticulture, for though he is best known to the horticultural world as the author of the "Fruit Manual," he was also a keen florist, being very fond of florist Tulips. Of these he had an extensive and valuable collection, and he continued to cultivate them until the close of his life at his home in Sussex. Having so much in common, we had much pleasant intercourse, and when his death occurred it was a great pleasure for me, in conjunction with my friend Mr. Harry Veitch and several other of his friends to obtain a die which was presented to the Royal Horticultural Society. From this medals are cast every year and presented to successful fruit growers under the designation of the Hogg Memorial medals.

Some years later I became in 1861 the Editor of the "Floral Magazine," published by Messrs. Lovell, Reeve & Co. There was a great dearth of floral artists in those days. Mr. Fitch was the artist to the "Botanical Magazine," and as that was published by Messrs. Lovell, Reeve & Co., he was naturally chosen as the artist for the new venture. However artistic his drawings were he did not satisfy the raisers of florist flowers to which the new magazine was especially devoted. I had therefore to engage the services of Mr. James Andrews, who for several years had been well known as the artist for various publications, and he undertook the work of the pictorial portion of the magazine. Many persons contended that the drawings which he made were not the flowers as he saw them, but rather idealised. Be this as it may, the popularity of the magazine rapidly increased, and as it was a time when general prosperity was increasing by leaps and bounds, it came in for its full share of success.

After some years Mr. Andrews retired from the post of illustrator, whereupon it was taken up by Mr. Worthington G. Smith, and we worked together until the time came that I, too, gave it up. It was always a difficult matter to know what flowers to choose, for four had to be selected each month. I have no doubt that mistakes were made, and as I look at the volumes now I am forced to confess that some of the strictures made were just, but it must be remembered that some of the flowers figured were essentially formal in themselves, and consequently were very difficult to make good pictures of. They were all coloured by hand, and in that respect presented a feature peculiarly their own, as there was no other publication of the kind at that time.

Two events as I said before occurred in the sixties of peculiar interest to horticulturists; one the opening of the Royal Horticultural Society's gardens at South Kensington, the other the grand exhibition of 1866. The ground of South Kensington had been acquired by the society from the Commissioners of 1851, and they passed it over to the Society, holding a mortgage on it. This in effect left them in the position of owners, for it was stipulated that if the Society failed to pay the interest it should forfeit all rights under the deed. I believe that about £120,000 was the amount of the mortgage, and it soon became evident that the whole thing was not intended to advance the interests of horticulture, but to be a sort of recreation ground to those Fellows of the R.H.S. who lived in the neighbourhood. The opening day was, however, most auspicious; a large number of plants were collected and the fine conservatory and the arcades were well filled, new and rare plants were brought forward, and all seemed to promise well. There were many, notwithstanding this, who shook their heads and were inclined to adopt the saying of General Pelissier when he saw the magnificent charge of the Light Brigade at Balaclava, "It is magnificent, but it is not war;" saying "This is all very fine, but it is not horticulture." For many years the society dragged on a troubled existence at South Kensington, until at last the R.H.S. shook itself free from the entanglement.

My recollection of the exhibition at the opening of the gardens centred especially around two plants; one was the first flowering bulb of *Lilium auratum*, exhibited by Messrs. James Veitch & Sons of Chelsea. Drawings of this gorgeous flower had been sent from Japan, and some people regarded them as the result of the imagination of the Japanese artists, while others, who knowing how faithful they had proved in the representation of other flowers, believed that we should one day see this gorgeous Lily as delineated. The other was a group of that beautiful terrestrial Orchid, *Disa grandiflora*, exhibited by my

friend the late Mr. Charles Leach of Clapham. The plant had been well known as having only one habitat in the world, Table Mountain in the Cape of Good Hope, whence it was introduced in 1825, but no one seemed to succeed with its culture. Mr. Leach had correspondents at the Cape, and from them he obtained such information as led him to achieve a great success. It had been the habit of cultivators to dry off the bulbs, and thus to insure their failure. As Table Mountain is mostly enveloped in fog and mist there is a continual moisture kept up, in which the plants luxuriate. Mr. Leach observed that when the flowering stem died off a new shoot had been formed at its base, which was in fact the bulb for the future plant. It was no wonder then that those who were interested in new and rare plants clustered around this group, and I shall never forget the exultation of that good gardener, Donald Beaton, how he kept calling people to come and admire them, and how he praised the beauty of the plants.

The Government of Cape Colony, seeing how the plants were being carried off, has forbidden its exportation now. It is a somewhat remarkable thing that many of our very largest Orchid nurserymen

Orchids at Wellesbourne House.

THERE is usually something good to be seen in the gardens connected with the above Warwickshire mansion, as W. M. Low, Esq., is thoroughly interested in all matters pertaining to gardening, and his able gardener, Mr. H. Liney, spares no effort to provide special features, of which his employer may be justly proud. Three years ago Orchid culture was taken up in earnest. A range of houses fitted with every modern appliance was erected, and large numbers of Orchids were obtained from various sources, the majority of them

FIG. 106.—DENDROBIUMS AT WELLESBOURNE HOUSE.

are obliged to confess they can do nothing with *Disa grandiflora*; and that while they can show you thousands and tens of thousands of *Cattleyas*, *Odontoglossums*, and *Cypripediums*, they are obliged to confess, if you ask them about *Disas*, that they can do nothing with them. I had this answer lately from two very eminent London firms, and yet I know of others who succeed with them. A good many seedlings have been raised, but many of them lack the lustrous beauty of the typical plant.

It was a long and dreary time through which the Society passed; members were elected on the council who knew nothing of horticulture and cared less, and the charter clung round the neck of the Society like a millstone, while no possible outlet from the imbroglio seemed likely. However, at last deliverance came, and those only who felt the bondage of those miserable years can realise the security and peacefulness of the Society in its present state. A great deal of this is owing to the resourceful energy of its present accomplished secretary the Rev. W. Wilks. Larger schemes are in contemplation, but at the present juncture it would be unwise to speak of them until they are more fully developed. If the new movement should prove as prosperous as the last, the Royal Horticultural Society may yet realise the hopes of half a century of enthusiasts.—D., Deal.

being newly imported. These were started in crocks in the usual way, and afterwards potted in a mixture of peat and sphagnum. A year after, when I saw them, the plants looked extremely promising, but rapid strides have been made since then, and the accompanying illustration (fig. 106) will convey some idea of the wealth of flowers with which the *Dendrobes* were studded. A finer display of these brilliant spring flowering Orchids it has never been my lot to see.

Some of the growths on *D. Wardianum* were upwards of 3 feet in length, carrying as many as thirty-five finely developed flowers. The old, yet still popular, *D. nobile* was strongly represented, some of the forms being exceptionally good, far in advance of many of the varieties still grown. Plants which show a decided improvement in the form or markings of their flowers unfortunately do not always grow and flower so freely as inferior varieties, but in this case the dual good qualities were combined. A single plant in one instance carried no less than 227 flowers, and several others must have produced almost as many.

Other species in flower were *D. thyrsiflorum*, *D. phalenopsis*, *D. Ainsworthi*, *D. crassinode*, and many others. A few *Cattleya* flowers were already expanding, and healthy plants and flower sheaths gave promise of beautiful things to come. The hard, strong

growths of the Dendrobies, and perfectly healthy foliage of other kinds, led me to inquire of Mr. Liney to what special details of culture he attributed his success. He was very emphatic in his reply, the substance of which may be put in a few words. During the growing season the Dendrobies were constantly surrounded by a moist atmosphere, a natural kind of moisture, promoted by employing gravel to cover the walks and stages. The temperature of the house was never at that stage allowed to fall below 60°, the usual night temperature being from 60° to 65°, with a rise of 5° by fire heat in the daytime during dull weather.

After the growth was completed and hardened, a long and thorough rest was given, the plants being placed in a vinery during the autumn, and left there till the flower buds were well advanced, because if taken into heat at an earlier stage, young growths would start and check the flowers. The whole collection of Orchids under Mr. Liney's charge reflects the greatest credit upon all connected with it, and amply demonstrates that the individual plants received constant attention of the right skilful kind.—VISITOR.

Notes on Potato Culture.

THERE can be no excuse nowadays for growing inferior varieties of Potatoes, as new and at times improved sorts are freely distributed. The question of soil has, however, much to do with the cooking qualities, and it is folly to condemn certain varieties without a trial, because what is good in one locality may be quite worthless in another. The point is to test several and adhere to those that are a success, changing the seed every second year. Some varieties, although prodigious croppers, are not of good flavour, and quality in such an important article of food should be the first consideration. White skinned tubers are more generally grown than those that are purple or red skinned, and as a rule are of higher quality. There are, of course, exceptions to this. For instance, Beauty of Hebron, a red skinned variety, if not superior is quite equal in point of quality with the white Beauty of Hebron. There is no Potato that possesses higher quality than the latter. If I were compelled to grow only one sort it would be this, as tubers from it cook well when dug in August, and equally well the following April. Unfortunately it is a rather shy cropper.

There are mistakes made in Potato culture, and the most serious is that of not allowing sufficient space between the sets for the haulm to develop without crowding. Weak growth results from this, the leaves cannot mature owing to a want of light and air, and a quantity of immature tubers deficient in all essential points are the outcome. It is thought that by planting thickly a piece of ground will produce a greater weight of tubers. This is decidedly erroneous. Another mistake made, and it is also a common one, is in the preparation of the seed, or "sets." Too often they are kept in a big heap until required, with the result that the shoots are 6 inches long, weak and useless for any purpose. The best form of sets are those about 2 ozs. in weight, with shoots $\frac{1}{2}$ to 1 inch long, stocky, and of a dark colour, and the sets should not have more than two growths, in fact one strong one is sufficient. For ordinary garden culture the sets should be placed on end in a cool light room for about a month before they are required for planting. The planting will be done successionally from the middle of March to the end of April, when the main crop should be got in. The subject of cutting the sets previous to planting has caused much difference of opinion. Personally I do not think it matters whether they are cut or not.

The Potato likes a tolerably rich soil, but the addition of manure at planting time requires some forethought. When the soil is heavy and retentive of moisture the manure should be applied in the autumn, as over-luxuriance of growth predisposes to disease. Light land may safely be manured at planting time. Speaking of field Potato culture generally, I prefer artificial to farmyard manure; it is more easily applied, and is certainly successful. As an instance of the use of such manures, I have during the last three years grown Potatoes on the same land with the aid of Webbs' manure only, and with success. In the case of heavy soil, where the manure is applied in the autumn the surface should be left in as rough a state as possible, so that frosts can act readily upon it.

In any kind of soil I prefer to dig the land and plant at the same time, as the soil is then left light and free for the roots to work in. In the case of heavy soil where the manure has been dug-in, in the autumn I chop out with a spade a furrow 6 inches deep, sprinkling along the bottom of it a 2-inch layer of decayed vegetable refuse, wood ashes, and old potting soil. This prevents in a great measure the scabbiness too often noticed in Potatoes grown on heavy soils, especially in a wet season. Early varieties of the Ashleaf type may be planted 10 inches apart in rows 22 inches wide. The second crop, of which Satisfaction and Supreme are representative varieties, should not be less than 13 inches apart in rows 2 feet 3 inches asunder. Late varieties like Windsor Castle, Up-to-Date, or Triumph should have fully a yard of space between the rows, and not less than 18 inches in

the rows. The question of variety is largely a matter of opinion and individual taste. In addition to those already named, Ringleader, Sutton's Ninetyfold, and A1 ought not to be forgotten amongst the early sorts; while Supreme, Reliance, and Flourball might safely be added.—E. MOLYNEUX.

Useful Herbs.

Mint.

THE ordinary garden or Spearmint is in much demand in spring and early summer. It is often required earlier than shoots are produced outdoors, and when this is the case a good breadth of roots ought to be available, so that a portion may be lifted and transferred to boxes or pots for standing in a warm house or frame, where stems will soon commence growth. When well started transfer to a cooler position. If kept moist growth will continue to be produced, using the longest and stoutest shoots first. If not too greatly weakened by close cutting the roots may be replanted, but if better material is available discard roots which have been forced.

Where there is much demand for Mint a new bed should be formed each year. The present is a suitable period to carry out the work, as an abundance of stout young growths may be found, which can be planted and depended upon to grow well. Each shoot can be lifted, and have a considerable portion of its underground stem attached. An open position and fairly well worked soil ought to be selected for the growth of Mint. Cut a trench out with the spade and carefully lay in about 6 inches apart the most suitable growths which can be found. Fill in soil over them, make firm, and level. They ought not, unless the ground is very dry, to require water, but if planted in sunny weather give a supply before filling in the last soil. Plant in rows 6 or 8 inches apart. It is not desirable to pick the growth from this last bed the first season. If the demand is not great annual planting may not be necessary, once in three years sufficing. The roots extend in the soil in the course of a season, often beyond the boundary of the bed. These outside growths will be found the best for planting.

Parsley.

Parsley is in demand the year round, and some difficulty is frequently found in maintaining a liberal supply during winter and early spring if protection is not afforded, which is best given by the aid of a frame, though coddling the plants should not be adopted. Place a frame over a bed before severe winter weather sets in, but give abundance of air and exposure whenever possible. Protection is needed only against damp and frost. Two sowings of Parsley are usually sufficient for most gardens. One sowing should be made in spring, the other early in August. The first sowing carries on the supply through the summer, autumn, and winter, and the last comes into use the following spring, remaining profitable throughout the year. Parsley ought to be sown in drills 4 to 6 inches apart on good rich loamy soil, so that the growth is vigorous. By sowing in drills the plants are readily thinned out. This may be done gradually. The more space the seedlings have the better they will grow and develop into fine bushy plants. The late summer sowing does not produce very large plants, but they are of a character which are likely to resist damp better than those with dense foliage. Unless absolutely necessary they should not be protected, as the plants are mostly too small for picking from; nor should it be necessary to do so with larger plants established earlier in the season. A few plants might be established in pots in autumn, and stood in a cool house on the approach of bad weather. This stock will probably come in useful during the course of the winter, all that is required being that the soil should be kept moist, and the plants have plenty of light, picking off yellow leaves if they appear. A good strain of curled Parsley is the best for ordinary purposes, as handsome and ornamental leaves can always be found.

Sage.

Sage is an indispensable herb in every garden. It is a hardy perennial, and exists for several years as a bushy shrub. It is readily propagated from young growths taken off the old plants at this season, inserted in sandy soil, kept moist, and shaded until rooted. Sage is also easily increased from seeds, sowing now in shallow drills about 6 inches apart, and thinning out the seedlings to the same distance. Take the tops out of the small plants, to induce them to form bushy plants. After the first season the plants will flower annually. These should be nipped out before they open, as their development tends to exhaust the plants.

Thyme.

Common Thyme and Lemon Thyme are cultivated in all gardens, as the smallest selection of herbs would not be complete without them. Propagation is effected by seed and divisions of the old plants. Sow seeds in shallow drills 4 to 6 inches apart, and thin out the plants as they touch each other. When they become bushy tufts, lift and replant 6 inches apart in rows a foot asunder. Division is effected before active growth commences, making moderate sized tufts, with roots attached. Water in dry weather, keeping the soil free from weeds.—E. BARROW.

NOTES

& NOTICES

Recent Weather in London.—On the whole the weather in the metropolis during the past few days has been satisfactory, inasmuch as it has been decidedly favourable to most vegetation. Saturday was fine, as was Sunday until the evening, when there were thunderstorms accompanied by a miniature whirlwind and torrential rain. Monday was warm but only bright at intervals, while on Tuesday it was a little dull, and very close. At the moment of going to press on Wednesday it was wet.

Weather in the North.—The first week of May has been generally wet, and high winds have occurred, the 3rd and the following night being specially boisterous and showery. Monday in the former part was extremely wet, but the afternoon improved, and the evening was fine and genial.—B. D., *S. Perthshire*.

Jersey Potatoes and the Frost.—Supplementary to the note on page 372 of the damage to the Jersey Potato crop, we learn that one-half of the total acreage has been affected, whole fields being completely ruined. This is all the more disappointing, as the crop this year was a week earlier than usual and a good season was anticipated. The importance of the Potato industry to the island is evinced by the fact that over 60,000 tons of Potatoes, valued at over £333,000 were exported last year.

The Trees in Marylebone Road.—A correspondent writes to the "Morning Post":—"I believe that many of your readers will deplore the fact that the finest trees in London, the great Planes in the Marylebone Road, are about to be felled. Two are already down, and the others are doomed. These trees have been the wonder of visitors and the delight of tired Londoners for a century or more. Now, however, flats—at once the boon and the curse of London—are to take their place. Is there no help for it?"

Death of Mr. T. B. Haywood.—We learn with deep regret of the death on Thursday last, May 3rd, at Woodhatch Lodge, Reigate, of Thomas Burt Haywood, who was in the seventy-fourth year of his age. The deceased was well known at the Royal Horticultural Society, of whose council he was a member, and he attended the meetings in the Drill Hall with great regularity, but unhappily failing eyesight prevented his appreciating the exhibits to the full. It is difficult to say in what particular direction in horticulture his proclivities ran, as he maintained all departments of his garden—which has long been in the charge of Mr. C. J. Salter—at the highest state of excellence. Perhaps Orchids and Roses were the prime favourites, but Chrysanthemums, hardy and tender fruit, and general plants were all magnificently grown. Mr. Haywood was treasurer of the National Rose Society and of the Royal Gardeners' Orphan Fund, and he will be missed from the meetings of these and many other horticultural associations.

The Wearing of the Rose.—This new custom on St. George's Day has been described as a "handicap celebration." "Than the Rose," says the "Daily News," no one could desire a better symbol. Saint, date, and flower—they are three superlatives. But the bother is that Roses do not bloom in April. True, the nurseryman will do anything you ask him. Roses in April are within the easy reach of an art that can soar to Strawberries in December. But the performance is spoiled by the penalty, as the experiences of St. George's Day made plain. City men were invited, and consented, to pay a shilling for their buttonholes. In Throgmorton Street the celebration looked like a complete success. But in Kentish Town it didn't. The democracy, having abundance of patriotism, but a scarcity of shillings, was at a grievous disadvantage. A painful comparison was afforded with recent instances of floral symbolism. The busman's piece of Shamrock was as good as the banker's; the duchess's Primrose was no better than the dairymaid's. People on this occasion, however, were driven to awful alternatives. Some sported dilapidated bundles of petals that had been Roses once. Others bought French blooms—their poverty and not their patriotism consenting. A third class condescended to inorganic imitations. Unhappy creatures! To wear a paper Rose can be hardly more satisfying to the soul than kissing a wax-work doll."

The Queen's Visit to Ireland.—During her Majesty's stay at the Viceregal Lodge the utmost pressure was put on the shoulders of Mr. D. Watt, the head gardener, to sustain the floral department. Prior to her Majesty's departure she presented him with a diamond pin as a recognition of his services; the pin has V.R.I., surmounted with a ruby crown, and the letters are in diamonds on a background of enamel.

Exhibitions of Florists' Tulips.—We learn from Mr. J. W. Bentley, one of the most enthusiastic Tulip growers in the country, that the northern exhibition will be held at Middleton on June 2nd, and that Butley Show will be on June 8th. The London exhibition will be held in connection with the Temple Show, and will presumably last only one day, but of this we have no official intimation.

London County Council Scholarships.—Several scholarships are being offered by the Technical Education Board of the London County Council, including two, one to young men and one to young women, which will give free board and education for two years at the Swanley Horticultural College. Seven junior scholarships in practical gardening, open to boys between fourteen and sixteen, are tenable at the Botanic Society's school in Regent's Park.

Green Peas for Londoners.—It was stated in a recent issue of the "Daily Telegraph" that the Great Eastern Railway Company in the course of a year deals at its London goods station with about 500,000 tons of merchandise. Of this, one special branch—the Green Pea traffic—represents during the season as much as 11,600 tons. This tremendous bulk of produce is brought to London by special trains, and has reached as heavy a weight as 950 tons in one night, the delivery of it to the various markets at Spitalfields and Covent Garden, commencing as early as 9.30 P.M., taking all night, and up to 8.30 the following morning.

Fruit Prospects.—The prospects for the coming fruit season appear to be good generally, that is to say, quite up to the average. Recent gales have not improved matters, though the actual damage done has not been great. The season, however, will be somewhat late. This is to be, says a daily contemporary, a great berry year—Strawberries and Gooseberries promising particularly well—but the stone fruit yield will not be large. There is no reason to believe that there will be a shortage of Apples and Pears. At present Tasmanian Apples are having a wonderful sale, and Spain is going to send us some fine Cherries. Altogether fruit lovers should be able to have their fill this summer.

Gardening Appointments.—Mr. Charles Higgins, formerly head gardener to John Mansell, Esq., Edenmore, Raheny, Dublin, continues in the same position with the new occupier, — Guinness, Esq. Mr. A. Crombie, the eldest son of Mr. David Crombie, head gardener to the Hon. Viscount Powerscourt, Enniskerry, has been appointed head forester to Sir Herbert Maxwell, Bart., Monreith, Wigtonshire, N.B. Mr. Crombie gained a bursary, valued at £30, at a forestry examination held in Edinburgh about six months ago. Mr. J. C. Ireland, for the past eighteen months foreman at Ladykirk, Norham, Berwickshire, N.B., has been appointed head gardener to J. Beausire, Esq. Wethersfield, Noctorum, Birkenhead.

Agricultural Schools for Ireland.—There has been a great stir recently in Tullamore owing to the necessity of having an agricultural school in the vicinity. In the early portion of the past week a representative gathering was convened, the chief motion for discussion being, What are the best means of securing the advantages of the Technical and Agricultural Instruction Acts for the people of the town? The chair was occupied by the Very Rev. Philip Calliery, and after a fairly long discussion the following resolutions were agreed to. First, proposed by Mr. Wm. Adams, J.P., and seconded by Mr. James Hayes, J.P., "That considering the many benefits likely to follow from the establishment of agricultural as well as technical schools of education, it is hereby proposed that the necessary steps be taken for the introduction of such schools in our midst, and with this view a committee of the people of town and country, without distinction as to creed or class, be formed forthwith with the above object;" second, Dr. Moorehead, J.P., proposed and Mr. E. Williams seconded, "That the new department be placed under the supervision and management of Mr. Lavin, B.A., and his assistants;" and third, on the motion of Mr. John Power, seconded by Mr. W. R. Power, "That a committee be formed with power to add to their number if required, and to carry out as far as possible the ideas embodied in the above resolutions." Such a committee was formed, the secretarial work being entrusted to the Rev. Father Fitzsimmons.

The Earls' Court Exhibition.—The opening day did not pass without evidence of the inferiority of man. Fairy lamps are placed around the flower beds in the gardens, and these were all connected by an inflammable cord, which was so disposed that, the flame running along the line, the lamps were (or ought to have been) automatically lighted. It happened on Saturday that, while this process was in operation on one of the beds in the Western Garden, a cnrate, catching sight of the travelling flame, leapt immediately among the "Geraniums" and Lobelias, and stamped it out. Looking around, as for some acknowledgment of his presence of mind, he encountered the sad and reproachful gaze of the gardener's assistant.

Birmingham Gardeners' Association.—At the fortnightly meeting of the spring session, held on the 7th inst., Mr. W. B. Latham presiding, there was one competitor for the prizes offered by the committee for essays on the "Cultivation of Primulas, Cyclamens, and Winter Flowering Begonias." Mr. James Hales, Edgbaston Botanical Gardens, was awarded the first prize. He dealt with the respective subjects in a comprehensive and thoroughly practical manner. A useful discussion ensued. Mr. Geo. H. Thompson, Grove House, Walsall, a successful amateur orchidist, exhibited a young well grown example of *Cymbidium Lowianum*, to which was accorded a certificate of merit, and a similar award was granted to Mr. H. T. Martin, gardener to Lord Leigh, Stoneleigh Abbey, Kenilworth, for remarkably fine Seakale, the thirteen blades weighing collectively 11 lbs., being the produce of one-year-old "sets." An interesting collection of cut flowers from the Botanical Gardens also served to enhance the meeting.

Liverpool National Amateur Gardeners.—Good progress is apparent at each meeting, both in the attendance and in the exhibits. Mr. A. W. Ardran, the enthusiastic president, occupied the chair on Thursday last in the Common Hall, Hackins Hey, Dale Street. The chief business centred in a paper entitled "Notes on Plant Propagation," by Mr. J. Guttridge, curator of the Wavertree Botanical Gardens, which proved most interesting from every point of view. In sowing seeds, Mr. Guttridge said, it required forethought and practical experience, and that the majority of alpine and herbaceous plants should be sown in autumn or early spring. Propagation from stem and root cuttings, grafting, and hints on hybridisation were also discussed, a hearty vote of thanks being passed to Mr. Guttridge at the close. Among the exhibits Orchids were conspicuous, Mr. A. Dodd winning with a nice *Cattleya Mossiae*, and the buttonhole flowers of Mr. Drake and Mrs. McGregor were quite noteworthy. Mr. Ardran exhibited splendid cut Roses, Miss Hunter taking second honours. Mr. Dodd won the Fern prize, and Mr. R. H. Hoskyn the president's monthly prize with a fine selection of cut blooms.—R. P. R.

The Shrewsbury Show.—I have received the schedule of prizes for the show which is to be held on August 22nd and 23rd, and, as usual, such inducements are offered that prompt exhibitors to stage products of the highest possible character. For specimen plants and large groups a sum of upwards of £200 is allocated to four classes, the first prize in three of them being £25, and in the fourth £20. This cannot be said to be a bad beginning. The cut flower section is always a brilliant one at Shrewsbury, and this year should be no exception. The class for the tasteful representation of bouquets and baskets of flowers in a space of 10 feet by 5 feet should be a splendid one, as the prizes are £15, £12 10s., and £10 respectively, with a silver cup to the premier winner. For what may be termed "space" collections of Roses, Carnations, Dahlias, Gladioli, hardy border flowers, and Sweet Peas, generous provision is made, and a gorgeous result may be confidently anticipated. In the decorative dessert table class, as the prizes are £15, £12, £10, and £5, up-to-date arrangements may be expected in this beautiful feature of the show. The "champion fruit class" is bound to arouse much interest. The stipulation is for twenty-four dishes of British grown fruit in a space of 10 feet by 4½ feet, on terms clearly stated in the schedule. Plants and flowers are allowed for decoration, and for these special prizes of £3, £2, and £1, those for the fruit alone being £25 and a gold medal, £20, £15, and £10. The "highest cultural merit" of fruit is the great objective in this class, and judging the decorations separately is an excellent idea. Liberal prizes are also offered for other collections of fruit, including Grapes. About 150 prizes, ranging from £6 to 2s. 6d., appear to be offered by seedsmen for vegetables, of which there will, no doubt, be an overwhelming supply, and the exhibition as a whole must be on a scale of first-class magnitude and excellence.—A JUDGE.

Royal Meteorological Society.—At the ordinary meeting, to be held in the rooms of the society, 70, Victoria Street, Westminster, S.W., on Wednesday, the 16th inst., at 4.30 P.M., the following papers will be read:—"The Wiltshire Whirlwind of October 1st, 1899," by the late G. J. Symons, F.R.S.; "The Variations of the Climate of the Geological and Historical Past and their Causes," by Dr. Nils Ekholm, hon. mem. R.Met.Soc.

Isle of Wight.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Sandown on Saturday last, Dr. J. Groves, B.A., J.P., in the chair. Mr. Cor. Orchard, F.R.H.S., read a very interesting, suggestive, and practical paper on "Flowering and Ornamental Foliage Creepers for the Embellishment of House and Garden," which evoked a very instructive discussion. Mr. J. H. Perkin, Los Altos, Sandown, staged a magnificent and effectively arranged group of plants consisting of Ferns, Caladiums, Crotons, *Dracenas*, *Schizanthus retusus*, *Isolepis gracilis*, and *Coleuses*; also a fine dish of Royal Sovereign Strawberries. For the above exhibits he received the association certificate. Several new members were elected at the close of a most successful meeting.

April Weather at Dowlais.—Rainfall, 2.70 inches, which fell on sixteen days. Greatest falls, 0.48 inches on the 11th and 23rd. Same period 1899, 6.21 inches on twenty-one days. Temperatures: Mean maximum, 53.93°. Highest reading 74° on the 21st and 22nd; mean minimum, 32.87°. Lowest reading 19° on the 7th. Below freezing point on twelve nights. Mean of maximum and minimum, 43.40°. Mean sun temperature for the month, 64.47°. Highest reading 87° on the 22nd. There were eight sunless days. The prevailing direction of the wind was S.W. and N.E.—WM. MABBOTT.

April Weather at Hodsock Priory, Worksop, Notts.—Mean temperature of month, 47.1°; maximum in screen, 73.5° on 21st; minimum in screen, 24.8° on 2nd; minimum on grass, 13.3° on 2nd. No. of frosts in shade six, on grass nineteen. Sunshine, 148 hours, or 36 per cent. of possible duration. Difference from average + 18. Rainfall, 1.14 inch; difference from average - 0.60. Rainy days, twelve; maximum fall, 0.21 on the 24th. Rain from January 1st, 8.66 inches; difference from average + 1.81. A fine and dry month, cold at first, but very warm about the 20th. Sharp frosts in last week, heavy gales about the 12th.—J. MALLENDER.

April Weather at Belvoir Castle.—The wind was in a westerly direction twenty days. The total rainfall was 1.31 inch; this fell on fifteen days, and is 0.49 inch below the average for the month. The greatest daily fall was 0.25 inch on the 11th. Barometer (corrected and reduced), highest reading 30.571 inches on the 19th at 9 A.M.; lowest reading 29.232 inches on the 4th at 9 A.M. Thermometers: highest in the shade 73° on the 21st; lowest 23° on the 2nd and 26th. Mean of daily maxima 55.26°; mean of daily minima 36.26°. Mean temperature of the month 45.76°. Lowest on the grass 17° on the 26th; highest in the sun 126° on the 21st. Mean temperature of the earth at 3 feet 43.33°. Total sunshine 178 hours 25 min. There were no sunless days. The 21st inst. was the warmest April day we have had here since April 11th, 1894.—W. H. DIVERS.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

The first part of the week was dull and cold, the latter part was fine and very warm.

The Royal Horticultural Society.

The New Chiswick.

I AM conscious that after many influential persons have expressed the view that a "new Chiswick" is necessary, it is perhaps presumption on my part to offer a contrary opinion, but it may not be too late even now to ask whether the purchase of a new garden is certainly the best means of celebrating the centenary of the society. We have still twenty years of the Chiswick lease unexpired. Can we not make the best of Chiswick for at any rate some years to come, and devote our energies to obtaining by some means or other the new horticultural hall which is so sadly needed for the fortnightly shows?

From the crowded state of the Drill Hall, both as regards the exhibits themselves and the visitors, it must appear to everyone a necessity that some other place be found before long. This is as necessary for the work of the various committees as for the shows, and I cannot doubt that if £27,000 was raised or promised several years ago, a much larger sum could now be raised, when the society has reached a degree of popularity and success never before known, at least in recent years.—ARTHUR W. SUTTON.

THE meeting on April 25th was very satisfactory in several respects, first because it showed that a vigorous interest is taken in the society's affairs and prospects; and, secondly, because it is evident from the statements made by the president that the council wish to act in accordance with the Fellows' desires. An idea (which is evidently erroneous) had got abroad that the bye-laws were to be rushed through, and that the other important schemes as to new gardens and horticultural colleges were to be carried in a similarly hurried manner.

Seeing that the council could have no other object than the best interests of the society, it was, perhaps, somewhat unfortunate that the bye-laws had not been distributed to all the Fellows before the meeting; it was also regrettable in these circumstances that the proposal was made "that they be taken as read." But then we were told that the wish to save expense was the reason for the first mistake, and the desire to save the time of the meeting was the reason for the second. Economy in the management of a society is most laudable, and we might therefore rest assured that a council that endeavours to avoid expense in such details would not seek to commit the society to the risk of any enormous and doubtful speculations. This, in fact, was proved by the subsequent business.

Although four experts of unquestionable ability had inspected the much-talked-of Limpsfield site for a new garden, had duly reported upon it, and according to the resolution in the notice paper issued to the Fellows it was "the proposal of the council" to purchase the site in question, yet the whole matter was postponed and no definite information could be obtained respecting it. (See page 378.) It is to be hoped that the experts were duly rewarded for the time occupied and trouble taken; in fact I am persuaded that the Fellows would rather that the council had acted "generously" than "economically" in this respect. Still the intention to avoid expense is apparent even here, for though other sites had been proposed, the experts who visited Limpsfield were not required to report upon them.

Would it be too much to expect that while considering financial matters so closely the council will also give a thought to the pockets of the Fellows, and try and arrange that the next meeting to consider questions of so much importance shall take place on the same day as one of the fortnightly meetings?—A SURREY MAN.

Garrya elliptica.

MANY readers of the *Journal of Horticulture* will be indebted to Mr. E. H. Jenkins for the valuable information in the reference to this plant on page 373. That *Garrya elliptica* might well be far more extensively grown no one will dispute, but that it should prove as hardy as Mr. Jenkins states will be a surprise to many gardeners. I have seen it growing in several gardens in various parts of the South of England, but it has invariably been on walls, and usually those with a warm aspect. On one occasion a year or two back I noted a plant in the open in a south country garden, but it looked wretchedly unhappy, and its owner has, I believe, since discarded it entirely.

I should like to ask Mr. Jenkins if he considers that the soil in which the roots are working would have any effect on the hardiness of the growth? Possibly when the roots are in a somewhat rich and moist medium the growths produced would be over-luxuriant—sappy, in fact, and in such condition as would render them peculiarly susceptible of

damage from frosts. The position of the specimens referred to by your contributor seems rather to favour this assumption, as he states they are growing in a poor soil on a bank that is excessively dry in the summer. From Mr. Jenkins' tone I should fancy that the gardener (?) who pruned those *Garryas* would have a sorry time if he came within reach of the writer's vengeance. I can assure your correspondent that such senseless acts are all too frequent in small gardens all over the country, and they arise, as in this instance, from the employment of men who know no more about gardening than do the tools they are supposed to wield with masterly skill. It would have been more than a pleasure to me to see the superb specimens alluded to.—F. ROWE.

Judges and Judging.

I HAVE for many years been connected with the management of horticultural societies, as secretary and in other positions. In all those societies with which I have had anything to do, the same three judges were never selected for any two following shows. Presidents, chairmen, and judges, when chosen year after year soon feel that they have the freehold of the office, and however desirable it may be thought to have changes, it is difficult to do so without giving offence. I think it should be only where there is a very strong reason to the contrary that the same set of officials should be re-elected year after year.—W. B. S.

The Barr Daffodil Cup.

I AM sorry to observe from "S. H. B.'s" note on page 373 that he appears to think I wished in my original note (page 333) to belittle the collection of Daffodils exhibited by Miss Curry at the Drill Hall on April 10th. Nothing was further from my thoughts. I was present at the Drill Hall on the date named, and spent some considerable time at Miss Curry's stand, and was charmed with the variety contained therein and the general excellence of the flowers. That they were worthy of the high honour accorded to them I have no doubt, but I still maintain that the honour attached to the securing of the trophy would have been decidedly greater had there been keen competition. I feel sure your correspondent would find infinitely more pleasure in annexing a prize by the narrow margin of three or four points from other growers than he would when given a walk over. That many other Daffodil enthusiasts could have come forward with collections had they wished to do so, I do not doubt, and I am quite in agreement with "S. H. B." that means could have been taken for hastening the development of the flowers, which would be perfectly legitimate. Let us hope that if next season be similarly late some such methods will be resorted to for contesting the honour of securing the Barrian cup. I have no reason to doubt that Messrs. Barr & Sons would prefer to see a dozen competitors fighting a neck-and-neck race for the trophy they have provided for these charming flowers of spring.—DAFF.

A National Rose Day.

I AM glad to see that you have taken up the subject of a National Rose Day for England, and I have read with much interest the able article of your correspondent, "V. M. H." in the *Journal of Horticulture* of April 26th. Our recognised notable days are at present few, and a moderate addition to them would, in my judgment, prove beneficial rather than prejudicial to the industrial interests of the country. Holding this opinion, I willingly join in the advocacy of a Rose Day in honour of our national emblem. It should, I think, be fixed for the middle or end of June, when Rose blooms are plentiful, and the poorest could acquire the emblem at a very trifling cost.

"How, when, and in what manner the Rose became the emblematic flower of England" I am unable to say. I have searched from the time of the Romans, but from the fourth to the sixteenth centuries can find nothing worth recording down to the time of Charlemagne (ninth century), who desired it to be grown in his garden. Late in the thirteenth century, Count Egmond, son of one of our kings, took for his device a red Rose, and early in the fourteenth century an English coin was struck, stamped with a Rose, and called a rose-noble. Shakespeare's scene in the Temple Gardens (Henry VI., act ii., scene 4) was not, I think, the origin of the adoption of the Rose as our national flower. We must go further back than that. I have in my library badges (roses) in silver bronze of the Lancastrian party, but the card to which they are affixed affords only their recent history. In the various books I possess on the Wars of the Roses there is nothing to enlighten us on this particular point. If we take Shakespeare's scene as history it seems reasonable to conclude that the Rose was then the national flower, and was for this reason adopted as the badges of the contending factions. From any point of view we may, I think, fairly assume that both red and white Roses were grown in London gardens in Shakespeare's time.

But the main point at issue is the date of the adoption of the Rose as our national flower. This, I fear, cannot now be fixed. My researches,

limited, I own, lead me to the conclusion that it was adopted from the Romans. It was the flower of that people, and among the many marks of affection and regard for it, the warriors who had distinguished themselves by gallantry were allowed to wear it on their shields. This, in a warlike age, would bring it under the prominent notice of the natives of Britain in the first centuries of the Christian era, and from this distinguished exhibition of it the emblem was probably adopted. Let me say, in conclusion, that there must be many lovers of Roses with antiquarian tastes possessing wider opportunities and more leisure than I can claim who may be rewarded by a closer and more extended research.—WILLIAM PAUL, *Paul's Royal Nurseries, Waltham Cross.*

Amidst the Tulips.

The Chiswick Trials.

IN the course of a few more weeks the few enthusiasts in florist's Tulips will be glorying or despairing amidst the flowers of the year. It seems to many of us a matter for regret that such magnificent flowers as these should be getting deeper and deeper into a slough of despond as at present appears to be the case, and it will require the strenuous efforts of a number of experts to bring the flower back again to its former glory. As the florist's Tulip is produced by the chief of the remaining enthusiasts it is a flower that is quite perfect in its superb beauty, but unfortunately it is not given to everyone of us to be able to reach the acme of perfection. There are several things that militate against success in their culture, consequently the grower of more limited means and time forswears his allegiance to the florist's Tulips and devotes his energies to the ordinary single and double varieties. These formerly came to us exclusively from Holland, but during recent years at Rush in Ireland Messrs. Hogg & Robertson of Dublin have been experimentalising in the production of Tulips for sale, and with the most gratifying results. The flowers that have been shown from these Irish grown bulbs have invariably been splendid in colour, form, and size.

Needless to say there are many scores of varieties of the so-called Dutch Tulips, many of which are really not worth growing as thoroughly distinct varieties. This season the Royal Horticultural Society has conducted a trial of single and double Tulips in the much belittled Chiswick Gardens. The bulbs were planted in the beds in the square near the majority of the houses, and a further trial of practically the same varieties was made in the beds flanking the centre walk. It was curious as well as instructive to observe how very differently bulbs from the same source behaved in the two positions, and some varieties that in the square were well nigh failures were excellent in the main walk. In other instances the flowers were of about equal excellence in each instance, and, perhaps, it is needless to add others were decidedly the reverse. It has been a most interesting trial, and has taught good lessons as to what Tulips are suitable and *vice versa* for the soil of Chiswick. It may be said to have done more than this, however, for it is safe to assume that the variety which succeeds at Chiswick will luxuriate in gardens that are more favourably situated in respect of soil and atmospheric conditions.

It was on one day during the latter half of last week that this visit was paid, and it was considered particularly fortunate that on the day immediately preceding the Floral Committee of the Royal Horticultural Society had inspected the collection, and from Mr. S. T. Wright, the admirable superintendent, the names of the varieties that had been honoured with three marks were received. There were seventeen varieties recognised on the occasion noted, and these included new and old, single and double varieties. The majority of these are known by every gardener, and probably find a place in nineteen out of every twenty gardens where Tulips are grown. They, as a matter of fact are acknowledged standard varieties that may be relied upon to produce excellent flowers almost, if not quite, every season. It may, however, prove of service if the whole of the three-mark sorts are mentioned in these notes, with brief descriptions to such as may possibly not be generally known. A few are of such conspicuous excellence that they must eventually become universal favourites, and will continue so until raisers provide others that are in some way superior for the adornment of our gardens and our greenhouses.

To select one variety of any plant and say that it is the very best is usually a distinctly risky proceeding, but it may be ventured upon

with the Tulips, putting Maes in the position of honour. This is done because the writer is convinced that the opinion would be supported by the vast majority of people who visited the Chiswick collection. To all intents and purposes it is a perfect single Tulip, and one which must eventually find its place in gardens where these bulbous plants are largely used for bedding purposes. The plant comes about midway between the very tall and the very dwarf varieties in height, and is particularly sturdy in its handsome leafage. The flower is of the largest size, ranking in this respect with Proserpine and Keizers Kroon; the petals are of remarkable substance and of the richest crimson colour; in form the flower is practically faultless. Between Ophir d'Or and Mon Trésor there is very little to choose in point of actual merit, both occupying the front rank amongst yellows. The Dutch growers, it is said, do not recognise any dissimilarity, but the flowers were distinct at Chiswick both in form and very slightly in colour. Each is superb, and may well be grown both in pots and in the beds. The trio named received the distinguishing three marks on the occasion of a previous visit by the committee.

Let us now turn for a brief space to the seventeen selected at the last inspection. The majority of these are, as has been said, known to every grower, and included Joost Van Vondel, Joost Van Vondel white, a superb variety; Cottage Maid, Le Reine, La Belle Alliance, Thomas Moore, and Duchesse de Parma, singles; and Tournesol and Imperator Rubrorum doubles. These, it will be conceded, are all excellent varieties, as is proved by the number of years they have remained in high favour with growers who are ever keen enough to discard old sorts when new ones of distinctly superior merit are brought to their notice.

The remaining eight varieties were again comprised largely of singles, El Toreador being the only double. This is a magnificent Tulip with grandly built flowers of a peculiar colour that may perhaps be most easily described as delicate plum in the body with edges of pale orange; it is undoubtedly one of the best varieties in trial, and ought to attain to a great popularity. Single pure white Tulips of perfect form are by no means numerous, hence the appreciation that was accorded to David Tenier, which in the Chiswick collection is unrivalled. Pink Beauty is slightly misnamed, and might preferably have been designated Rose Beauty, as there is no pink in its flowers. It is really rose and white, and is strikingly effective. A delicately beautiful flower is Queen of the Netherlands, which is soft blush, and is thus in direct contrast to Dussart, as this is a glowing plum crimson; it is a most attractive Tulip. Amiral Renier, white and red, is very distinct, and will find many admirers, as also will Hector, a beautifully formed flower, which is exactly the colour of Pond's Seedling Plum, and has yellow edges. Last of all comes Grand Duc de Russie, a fine variety with purple flaked flowers.

It must not be inferred that these are the only Tulips of premier quality that have been grown at Chiswick this year. Such is by no means the case, as several indispensable varieties, of which we may quote Vermilion Brilliant, Keizers Kroon, and Proserpine as examples, were seen in splendid form. Those named have been chosen simply as illustrative of the fact that the Floral Committee on its most recent visit was desirous of recognising both old and new sorts that at the moment of inspection were considered sufficiently meritorious.—F. W. H.

The Embankment Gardens.

THE provisions that are made by the London County Council for the delectation of the public in various parts of the metropolis are a never failing source of delight to visitors. Go we north, south, east, or west there are parks and gardens in which bedding is carried out in splendid style; while even in the heart of London we find some peculiarly beautiful grounds. Amongst the most centrally situated are the Victoria Embankment Gardens, which strike at right and left angles from Charing Cross Railway Bridge. These grounds are not very extensive as compared with the great parks, but they comprise within their limited boundaries such beds of Dutch Tulips as would be a credit to any place in or out of London.

It need scarcely be said that the difficulties in growing satisfactory plants on this particular portion of our noble Boulevard are by no means limited in number. Trains are constantly crossing and recrossing the river, and they give forth innumerable atoms of burning dust, which

Fig. 107.—EARLY TULIPS.

fall in clouds upon the unfortunate plants below. Then the Underground Railway has a ventilation shaft in the eastern garden, and everyone who has ridden in these trains can form some idea of the noxious fumes that are belched therefrom. Then there are thousands of surrounding chimneys, which do their share towards making the work of satisfactory bedding more and more difficult of attainment. However, the superintendent, Mr. D. Carson, goes quietly onward, and by persistent effort secures excellent flowers.

A few days ago I made an opportunity of visiting the gardens to see the Tulips, in whose praise I had heard so much. The brilliant display of flowers came as a most agreeable surprise, even after the verbal reports that had reached me. There were, for the size of the gardens, considerable numbers of beds, in the major portion of which was one variety only. In the remaining beds and here and there in the shrubby borders were mixed single Tulips, and these produced a bright and striking effect; they were a change from the others, and as such meet with general approbation. Amongst these mixtures were observed Tournesol double, Van der Neer, and Gold Standard, which, with Vermilion Brilliant, are represented in the engraving (fig. 107). There were also, of course, all those about to be enumerated. Of the numerous one variety beds only one was a failure. It was represented by four beds in widely divergent portions of the garden, and of the several hundreds of bulbs not a solitary one produced a flower. Every one had grown strongly and produced fine substantial leaves, but when the bud was about a quarter developed there had come a complete cessation of growth, and the buds gradually shrivelled. The variety was supplied as Couleur Cardinal, which has in previous seasons been quite satisfactory.

This break in the otherwise beautiful series of beds was most regrettable, but was amply compensated for in the brilliance of many of the others. There were hundreds of flowers of such varieties as Proserpine, Chrysolora, Keizer's Kroon, Cottage Maid, Vermilion Brilliant, L'Innocence, Fabiola, Joost Van Vondel, and others that in respect of size and form were beyond criticism, but the colours were scarcely so clear as one is accustomed to find in the same varieties when they are grown in the pure air of rural districts.

While Tulips formed the brighter portion of the display when this visit was paid, there had been also beds of Crocuses and Scillas. Hyacinths were just passing their best, but a splendid bed of King of the Blues still remained. Later we shall have the summer bedding, and if this prove equal in its own way to the feast of Tulips, then will it be satisfactory to everyone concerned in its management, as well as to the public.—WANDERER.

Tulips at Long Ditton.

I LOOKED in at Messrs. Barr & Sons' bulb nursery at Long Ditton the other day to see the early Tulips. One peculiarity of these at this place is that they constitute blocks of colour here and there set into a vast ground of yellow formed by the huge masses of Daffodils. But that very fact served to bring out with marked emphasis the exceeding beauty and richness, as well as welcomeness of these diverse and generally glorious hues. In ordinary garden decoration I much prefer to see Tulips mixed up in several colours in beds as being so much more pleasing, but in such grounds as those of Messrs. Barr and Sons big blocks of one variety tell with diverse and brilliant effect because of the great range of other flowers all around.

How difficult is it to pick out from these early flowering Tulips one as being more beautiful than another. Sometimes the selfs seem best, sometimes the particoloured ones, and of these certainly Joost Van Vondel is a delightful variety. But all singles are lovely. All doubles on the other hand seem ungainly, indeed if there be any flower grown in gardens that seems to have been spoiled by doubling it is the Tulip. About the middle of the month, though necessarily much depends on the intervening weather, the splendid collection of late, and especially the so-called Darwin or self-coloured Tulips, will be at their best. These seem to me to be the most beautiful of all Tulips, and those who may not have seen them should try and do so this year, for they will be found in a huge block, and be wonderfully attractive. Whatever may be the peculiar properties of the Dutch soil, at least it seems difficult to believe that it can grow either Narcissi or late Tulips better than these bulbs are grown at Long Ditton in particular, and throughout Great Britain in general.—A. KINGSTON.

Royal Gardeners' Orphan Fund.

Annual Dinner.

It has become customary during the past few years to hold the occasional dinners of the gardening charities in the Hotel Métropole, but on this occasion a move was made to the Café Monico, Piccadilly Circus. This dinner is regarded as one of the social events of the horticultural world, and the muster on Tuesday evening was decidedly strong, about 130 gentlemen being present. The committee had been fortunate enough to secure the presence of Lord Battersea as chairman, and the company received his lordship with enthusiasm. Among the scores of well-known people observed were Messrs. W. Marshall, W. Cobb, W. A. Bilney, N. N. Sherwood, Leonard G. Sutton, M. Hubert Foquett Sutton, Jas. H. Veitch, J. Gould Veitch, Arnold Moss, H. Balderson, F. Q. Lane, D. Pell-Smith, G. Assbee, G. Monro, Peter Kay, J. O'Brien, H. B. May, J. F. McLeod, G. Gordon, R. Dean, J. H. Laing, J. Douglas, W. Cutbush, R. Cuthbert, S. T. Wright, G. J. Ingram, J. W. Moorman, and T. Bevan.

The dinner was despatched in a satisfactory manner, and the Royal toasts were received with the most intense enthusiasm. But everyone was looking forward to the chairman's speech, as he had come amongst them with the reputation of an orator—a reputation that was certainly maintained, for he had an abundant flow of beautiful language, and here and there a flash of wit. His lordship did not speak at great length, a fact that was evidently deplored by many of those in the International Hall. He expressed the gratification he had felt in being invited to preside, and at the pleasure it gave him to be present, to bring forward and to urge upon them the necessity for doing their utmost for a most admirable institution. He was sure the man of to-day found more pleasures in his garden than had been possible in years gone by, and he thought all would recognise in town and country that there was a rising intelligence perceptible about all connected with horticulture. There was, continued the speaker, another society—namely, the Gardeners' Royal Benevolent Institution—which all ought to support; but he considered that more should be done for the benefit of the orphans. His lordship referred to the interest Sir Francis Bacon found in his garden in the days of the great Elizabeth, and further assured his hearers that in his garden and amongst his plants he found a greater peace and a deeper interest than in politics. Everyone, he said, could grow flowers, though Orchids were beyond the means of many. These might, however, find equal enjoyment in the humbler flowers of the garden. He thought those who could afford to give £400 or £500 for a single Orchid, as he had that day heard of, should give generously of their wealth to the institution. He considered this an age of progress, and brought forward examples to illustrate his points. He was thankful, as a sign of the times, to find formal bedding going out of fashion, due, of course, to the broader and more intelligent views with which ladies and gentlemen were looking at their gardens.

N. N. Sherwood, Esq., the treasurer of the Fund, rose to thank Lord Battersea for his presence and for his eloquence, and to bring to the particular notice of those present a few facts about a society in whose welfare all were interested. He briefly reviewed the work that had been done during the past thirteen years, and characterised it as most satisfactory, but still, he considered, the support of gardeners generally in the form of annual subscriptions ought to be greatly increased. Though he believed them to be underpaid he thought a subscription of 5s. a year could not hurt anyone. He thought head gardeners might have a fund amongst the foremen, journeymen, and labourers; that they might seek permission from their employers to place boxes in the mansion when it was full of guests; and that children might be given boxes for collecting, all of which would tend to increase the funds and therefore the utility of the society. The committee was spending £1000 a year and had an income of £390, and he hoped within the next two or three years to find these figures more in a line.

Mr. Jas. H. Veitch was entrusted with the toast for "Gardeners and Gardening," and he spoke briefly but forcibly. He thought the society largely existed to assist the smaller man, and asserted that he weekly saw several letters offering such men as this less than the local vestries pay for street cleaners. This, said Mr. Veitch, was not encouraging to men either to join or remain in the ranks of the profession. He considered that nothing more striking than the marked revival in gardening could be found, and trusted that some of the present wave of prosperity would fall upon the gardeners. Mr. Richard Dean responded at considerable length. The toast of the chairman was proposed by Mr. H. B. May, and that of "the Press" by Mr. W. Marshall, the latter being responded to by Mr. G. Gordon.

The subscription list must be characterised as exceedingly satisfactory, and proves the deep interest that is taken in the Fund. The total amount was, in round figures, £590, which is only about £30 below last year's total. Towards this sum the Right Hon. Lord Battersea contributed £25, Messrs. de Rothschild & Son 50 guineas, Mr. N. N. Sherwood £50, Messrs. Barr & Sons £28 16s. 6d., Mr. G. Assbee's Covent Garden table £77 15s., Mr. Leonard Sutton £25, Mr. Martin H. Sutton £25, Sir Trevor Lawrence, Bart., 10 guineas, Baron Schröder 10 guineas, Mr. J. T. Gabriel 10 guineas, Messrs. J. Veitch & Sons 10 guineas, Mr. H. Richards 10 guineas, Mr. W. Poupart's table £37 6s., and Mr. Thomas Walters, the Orchid expert, £30 3s. 6d.

An Obnoxious Weed.—It is said that Mr. Monk, M.P. for Gloucester, intends calling the attention of the First Commissioner of Works and the House of Commons to the fact that there is a continual growth of some tiresome weed in the lake in St. James' Park, which, rising to the surface, gives forth an offensive odour. Visitors to the park have often noted this unpleasantness. The lake is periodically emptied and thoroughly cleaned out, but the weed never fails to spring up again in obnoxious luxuriance. Its growth is something of a mystery, because the bed of the lake is of concrete.

Deutzia Lemoinei.—In March, 1896, a first-class certificate was awarded for this handsome shrub by the Royal Horticultural Society, and that the distinction was well merited is evident from the way it has risen to the foremost ranks of flowering shrubs. It is a hybrid between *D. gracilis* and the rare *D. parviflora*, and partakes of the good qualities of both plants. The flowers (fig. 108, page 401) are white and produced with great freedom from almost every bud on the previous year's wood. They are borne in large upright panicles, and last well. For cutting it is superior to *D. gracilis*, and the flowers are seen to greater advantage. Although perfectly hardy it will never be so popular for outdoors as it is for forcing, the flowers opening early and being liable to damage from cold winds or frost. Good plants may be obtained in two years from cuttings, which should be established in pots in autumn to force in an intermediate temperature during winter and spring.—D.

Preserved Pine Apples.—Quantities of canned Pines, as they are called in the trade, have recently been unloaded in our docks, and many hundreds of thousands of tins containing this fruit preserved in syrup are in the hands of dealers. Something like 5,000,000 Pines are exported annually from Singapore, the bulk coming to the United Kingdom. The cultivation and exportation of this fruit are mostly carried on by Chinese. It is nothing for the firms engaged in the trade to prepare 10,000 Pines in a day. The fruits are partially pared, and the juice with which they are surrounded is made from partly ripened Pines, sweetened with white Java sugar. When the tins have been tested they are put up in cases carrying twenty-four each. Some retail traders in this country, says a contemporary, take the Pines out of their tins, and by a simple process turn them into a preserve, which is sold at about double the price of the canned fruit. Put up in glass jars, the preserve obtains a ready sale.

Dahlias.—To what is due the remarkable popularity of the Dahlia seen to-day? Is it the result of the work of the National Dahlia Society, or the introduction of the Cactus section, or have both these things operated in the direction named? Certainly Dahlias are grown now in immense quantities, and are a most important article of commerce to florists. I was in a Dahlia florist's place recently and saw young plants propagated from cuttings by apparently tens of thousands. They seemed to have been nearly all ordered, and were in process of being sent out; yet this is only one such nursery out of fifty perhaps, possibly several fifties, that make Dahlias a speciality, and put their tens of thousands into commerce annually. It would be interesting to learn from some of the Dahlia traders as to which section of these flowers is in greatest demand; no doubt it is the Cactus section, for these seem now to be more widely grown than any others, and that is perhaps no cause for surprise, seeing that whilst all other sections increase in variety slowly these Cactus forms come on yearly by leaps and bounds, and private growers find it difficult to keep pace with the raisers who put several dozens of new ones into commerce each year. Yet is it interesting to find that Shows, Fancies, and Pompons are in great demand relatively, as also are the garden or decorative forms, which seem largely now to consist of rejected Cactus varieties. We must give to the National Society and its shows some credit for the Dahlia's present popularity, for much has been accomplished through its agency. Many of the provincial horticultural societies, too, have done very much to popularise the Dahlia through the establishment of various classes. Evidently the Dahlia is in for a long innings of floral popularity.—A. D.

French Scent Farms.—The work of picking some of the flowers on the French scent farms has begun. The flowers mostly cultivated are the Violet, the Jonquil, and Mignonette, which are picked in February, March, and April. Roses, Orange blossom, Thyme, and Rosemary are gathered in May and June, Tuberoses and Jasmine in July and August, Lavender in September, and Acacias in October and November. But the most important crops of flowers are the Roses and Orange blossoms, the others being mostly grown by small cultivators in the rural districts among their Vines and Olives. One of the largest flower farms is at Seillans, about 2000 feet above the level of the sea, and twenty miles from the coast, upon the southern slope of the Alpes-Maritimes.

The Use of Nettle Fibre.—The American Consul at Glauchau (Germany) reports that Nettle fibre has of late come greatly into favour in the manufacture of fine yarns and tissues. In Germany, there are factories which use these fibres both in spinning and also for ulterior purposes. In Nettle spinning alone over 10,000 spindles and some hundred workmen are employed. The raw material is imported almost exclusively from China, whence 661,500 to 802,000 lbs. are annually sent to Germany. Nettle fibre produces one of the finest tissues obtainable from any known kind of vegetable fibre, and in view of the importance which this seems likely to attain in connection with the weaving industries, it is intended to introduce the cultivation of Nettles, if possible, into the Cameroons. The idea is to prepare the products of this experimental culture at the place where they are obtained, and test them in German factories. Should favourable results follow from these experiments, it is intended to organise Nettle growing enterprises on an extensive scale.—("Indian Review.")

The Wild Arum.—This interesting plant is now unfolding glossy, spotted leaves by the wayside, and shortly the pale green spathe will be conspicuous. The curious, brown, club-shaped column, on cutting open the neck of the spathe, will not have completed its growth, but one may see, says a writer in "The Echo," the separate parts of it in three groups. Below are the female blossoms, each consisting of a single ovary. Above these are the male flowers, each with a single stamen. Then a ring of slender pointed leaves, or flowers. The latter resemble hairs pointing downwards. They appear to guard the narrow entrance, where they form a kind of trap, like the old-fashioned mousetrap—insects can creep down them, but cannot return. These tiny flies may be found within, creeping about, and their coats dusted with pollen from another plant of the species. But they find no pollen, as the female flowers ripen first. Having made a discovery they endeavour to escape, but in vain, the pointed hairs bar the passage. Then after the female flowers have been fertilised the males begin to ripen and shower the golden pollen on the insects below. Presently the hairs wither away, and the road is open for escape. Such is a brief history of Cuckoo Pint. If the spathe is cut open later in the season, small midges are found who seem to have ate ravenously and perished.

Border Polyanthuses.—Persons who gathered their notions of what were good or prize border Polyanthuses from the plants seen at the Drill Hall on the 24th ult., those from Mr. Bennett Poë's garden being an exception, could they have seen the huge bed of these Polyanthuses I saw a day or two since at the Swiss Nursery, Farnham, would have realised the great difference there is between poor strains and good ones, and between plants shown under somewhat artificial conditions and those growing outdoors in pure air and in broad sunshine. I went all the way to Farnham the other day on purpose to see these beautiful spring flowers. It is really surprising to find how wonderfully well they thrive fully exposed to frosts or hot sunshine on a somewhat thin, sandy, and stony soil taken out of the starved heathland of the locality. There were plants of brilliant yellows, whites, mauves, reds, crimsons, and purples that I should as seed stock plants have regarded as worth half a guinea each, because it is only by saving seed from such and sowing from year to year, that stock can be improved. The entire collection formed in the declining sunlight of a May afternoon a most beautiful picture. Already several thousands of strong seedling plants had been put out for next year's flowering. Mr. Mortimer finds on his sand, as I used to find on the Middlesex clay, that sowing seed at the end of August and wintering the plants as he did in boxes in a cold house, or as I used to do in beds outdoors all the winter, and then planting out in April, to be the very best plan. All these seedlings will be large clumps next April, and give a glorious profusion of bloom.—OBSERVER.

The Royal Horticultural Society.

Drill Hall, May 8th.

THE exhibition in the Drill Hall, as is usually the case at the meeting immediately preceding the Temple Show, was not very large. Orchids, though not numerous, were of excellent quality, as were the few fruits and vegetables, and the diversified floral exhibits.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with the Rev. W. Wilks, and Messrs. H. Esling, J. Cheal, P. C. M. Veitch, A. H. Pearson, G. Kelf, A. Dean, S. Mortimer, H. Markham, J. H. Veitch, E. Beckett, J. Smith, F. Q. Lane, G. Norman, J. Willard, G. Bunyard, H. Balderson, G. Wythes, H. Somers Rivers, and G. Reynolds.

Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, sent a fine collection of sixty dishes of vegetables, which included not only early forced varieties, but many well-kept dishes. The Kidney Beans Syon House in pots were carrying a good crop. Carter's Market Spinach, Ellam's Early Cabbage, Carter's Daisy Pea, Cabbages Sutton's Early April, Favourite, and Veitch's Maincrop were noteworthy; as were also good dishes of Leeks, Sutton's Dwarf White Broccoli, Seakale, Early Large Red Tomatoes, Asparagus, Veitch's Perfection Cucumbers, and English Beauty Potatoes (silver-gilt Knightian medal).

Messrs. Laxton Bros., Bedford, had the honour of staging the first fruiting plants of St. Antoine de Padoue Strawberry, a cross between St. Joseph and Royal Sovereign. The variety is certainly a good step towards improving this race of Strawberries. The fruits were large, showing the Sovereign cross, while the habit is still that of St. Joseph, certainly a successful cross. Mr. G. Norman, gardener to the Marquis of Salisbury, Hatfield, sent two boxes of Royal Sovereign Strawberry; the fruits were of immense size, while the colour and general finish left little to be desired (silver Knightian medal). Mr. M. Masterson, gardener to the Earl of Camperdown, Shipston-on-Stour, staged nine dishes of fruit, the specimens of Uvedale's St. Germain being enormous, while the Apples included well preserved dishes of Tom Putt, Blenheim Pippin, Hanwell Souring, Allen's Everlasting, and Nutmeg Pippin, with a good dish of Royal Sovereign Strawberry (silver Knightian medal).

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, R. Dean, G. Reuthe, W. Howe, J. Hudson, J. F. McLeod, R. B. Lowe, R. Fife, C. Jefferies, H. J. Jones, C. E. Pearson, H. J. Cutbush, C. E. Shea, E. H. Jenkins, W. J. James, J. W. Barr, G. Paul, E. T. Cook, C. T. Druery, J. Fraser, E. Mawley, and J. D. Pawle.

Messrs. Jas. Carter & Co., High Holborn, arranged a large semi-circular group of Cinerarias of the cruenta type, with a groundwork of the double forms. The former section was represented by a large variety of colours, and judging from some of the smaller plants, the firm intends producing the bright colours of the ordinary type, which will be a great gain. The double varieties were excellent in habit and variety of colour. From Messrs. J. Laing & Sons, Forest Hill, came a collection of standard Azalea mollis, Viburnums, double Lilacs, Wistarias, and double Prunus, arranged with variegated Acers, Bambusas, and small Azalea mollis; also a Japanese Azalea named Toduguma, a double lilac form; and a variety of hardy flowering plants (silver Banksian medal). An attractive exhibit was staged by Messrs. J. Cheal & Sons, Crawley, comprising a large variety of flowering shrubs, forming a most interesting display. The Pyruses were a special feature, and included P. Halleana, P. Imperial, P. floribunda, P. spectabile fl.-pl., P. floribunda, P. prunifolia, P. Nikita, a white flowering form, sweet scented; P. Malus atro-sanguinea, perfect wreaths of bloom; P. M. Kaido, a delicate pink variety; and P. Niedwitzkiana, a new variety with rosy red flowers, which should make a valuable addition to this class of ornamental trees; the whole was arranged with a variety of ornamental foliage (silver Flora medal).

A very bright and attractive display of spring flowering bulbs were staged by Mr. H. J. Jones, Ryecroft Nursery, Lewisham, which included some beautiful bunches of Spanish Irises, such as Thunderbolt, Baron Von Humboldt, Albambra, Sensation, Snowball, and Chrysolora. Tulips such as T. elegans, T. Picotee, T. vittellina, and T. fulgens, also a good variety of the Dutch forms (silver Flora medal). A most interesting exhibit of hardy flowers were staged by Mr. Amos Perry, Winchmore, Hill, N., which made a capital display. Phlox amœna, Geum Heldreichi, Trollius europæus, Doronicum magnificum, Euphorbia polycroma, Arnebia echioides, and a large variety of other plants were conspicuous (silver-gilt Flora medal). Mr. M. Prichard, Christchurch, Hants, also arranged a table of hardy flowers, which attracted much attention. The collection included large bunches of Euphorbia pilosa major, Phlox canadense, Trollius caucasicus Golden Globe, Rhodiola aurantiaca, and Oxalis enneaphylla (bronze Banksian medal).

Messrs. F. Cant & Co., Braiswick Nursery, Colchester, brought the only display of Roses, which included vases of the old Austrian Copper and Harrisoni, also the new Polyantha Roses Thalia, Euphrosine, and

Aglaia, while a box of specimen flowers included good examples of Madame Cusin, Maréchal Niel, Mrs. S. Crawford, and Rainbow. Messrs. Jas. Veitch & Sons, Ltd., Chelsea, arranged a fine group of spring flowering plants such as Hydrangea Mariesi, Azalea mollis, with beautiful Japanese Acers and other foliage plants, forming a pleasing exhibit. Messrs. Hogg & Robertson, Rush, co. Dublin, staged a large collection of cut Tulips, all grown in first-rate form, the blooms being large and of good substance. The chief varieties were Lac Doree, Silver Standard, Californica, Shusnas, La Panache, Fulgens, Golden Eagle, also a collection of Darwin Tulips, which might have been staged more attractively (silver-gilt Banksian medal). A most interesting exhibit was staged by Messrs. T. S. Ware, Ltd., Feltham. The most noteworthy feature of the exhibit were some Iris Susiana of enormous size and perfect condition, Primulas Sieboldi, japonica, obconica, and farinosa, also a collection of rock and alpine plants, in which the Saxifragas, Gentianas, and Aubrietias were conspicuous.

Messrs. G. Jackman & Son, Woking, contributed a display of hardy flowers, which included some typical Narcissi, large pans of Trillium grandiflorum, Dodecatheon splendens, Daphne cneorum major, and Phlox canadense, also a few choice Alpines, Tulips, Mount Pæonies, and a lovely plant of Clematis Princess of Wales (silver Banksian medal). Messrs. W. Cutbush & Son, Highgate, arranged a large exhibit of spring flowering plants of the decorative type; the Ericas were crowded with flowers, the Boronias elatior were triumphs of skill, Calla Elliottiana, Lilac Madame Lemoine, and the Azalea mollis were also noteworthy. The whole was admirably arranged with Ferns, Palms, and foliage plants (silver Flora medal). Mr. A. Zumbod, gardener to Miss Jekyll, Munstead Wood, Godalming, staged two splendid baskets of Polyanthus Primroses in yellow and white. The colours were artistically arranged and were much admired, the plants clearly exhibiting signs of good culture (bronze Banksian medal). From Messrs. J. James and Sons, Farnham Royal, came a basket of Polyanthus of the gold laced type. Mr. Knowles, Woking, staged a magnificent basket of Daphne cneorum, a perfect mass of rosy pink flowers.

Messrs. Barr & Sons, Covent Garden, sent a collection of Darwin Tulips, which included good bunches of Cordelia, The Sultan, Early Dawn, Purple King, and Loveless, also a gorgeous display of Dutch varieties, with a few hardy alpine and rock plants, in which Viola pedata bicolor played a prominent part (silver-gilt Banksian medal). The same firm also arranged a collection of Daffodils, which included bunches of Sentinel, Stella superba, Prince of Wales, Hon. Mrs. Barton, Dorothy G. Wemyss, P. R. Barr, St. John's Beauty, and Madge Matthews, with many others that have already been noted in these pages. Miss Willmott, Warley, Brentwood, sent vases of N. Bernardi, Philip Hurt, Louise, Poeticus grandiflora, and a delicate form of Ornatus. Messrs. J. Veitch & Sons, Ltd., Chelsea, staged a vase of Ivanhoe. From the Rev. G. H. Engleheart came three seedlings of the Poeticus type, Shelley, a fine form, Sonnet, and Rondo.

ORCHID COMMITTEE.—Present: Norman C. Cookson, Esq. (in the chair); with Messrs. H. J. Veitch, de B. Crawshay, H. Little, H. J. Chapman, W. H. Young, H. A. Tracy, J. Wilson Potter, H. T. Pitt, E. Hill, J. Jacques, T. Rochford, J. Colman, W. Cobb, J. Douglas, and C. J. Lucas.

Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, contributed a magnificent collection of Orchids. The splendidly grown plants were admirably arranged, and formed one of the most attractive collections in the hall. There was a central group of Lælia Latona, with Cattleya Mendeli on the one hand, and C. Schröderæ on the other. Amongst the remaining plants were observed Odontoglossums triumphans, cirrhosum, and crispum; Oncidium ampliatum, pulchellum, concolor, and phymatocarpum; Dendrobiums thyrsiflorum, Alcippe, atro-violaceum, and obscurum; Cattleyas Schilleriana, Daphne, and Lawrenceana; Lælio-Cattleyas Ascania, Wellsiana albida, Zephyra, and highburyensis; Bifrenaria Harrisonæ alba, Epidendrum elegantulum luteum, O'Brienianum superbum, elegantulum, and vitellinum; Chysis langleyensis, Epiphronitis Veitchi, Cymbidium Lowianum, Cypripedium Lawrenceanum, Miltonia flavescent, Rodriguezia pubescens, Spathoglottis aureo-Veillardii, Bifrenaria Harrisonæ, and others (gold medal).

Mr. W. Walters, gardener to Col. Shipway, Chiswick, contributed a small group of Orchids, in which Cattleyas, Lælia purpurata, and Dendrobiums were conspicuous (silver Banksian medal). Mr. F. W. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill, sent some excellently grown Odontoglossums, Cattleyas, Miltonias, Oncidium, and Lælias (silver Flora medal). Mr. N. P. Bound (gardener to Jeremiah Colman, Esq., Gatton Park, Reigate, sent two baskets of Orchids arranged with Asparagus. The smaller one was silvered wicker, and was lightly arranged with Vandas, Masdevallias, Cattleyas, and Sophronitis grandiflora. The larger contained some excellent Odontoglossums and Cymbidiums. Mr. Bound also showed a superb variety of Odontoglossum Ruckerianum. Mr. W. H. Young, gardener to Sir Frederic Wigan, Bart., Clare Lawn, East Sheen, sent some handsome Cattleyas. Amongst other exhibitors of a few Orchids were Messrs. de Barri Crawshay, F. Hardy, A. H. Smee, G. F. Moore, C. Bovill, W. M. Appleton, F. Sander & Co., and R. I. Measures.

One of the most superb groups of Orchids in the hall was that from Mr. Geo. Reynolds, gardener to Leopold de Rothschild Esq., Gunnersbury

Park, Acton. It consisted wholly of magnificently grown plants of *Vanda teres*. There were several dozens of plants in boxes, with a background of Palms, and a foreground of Palms and Ferns. The flowers were perfect in all respects, and the group was probably the first of its kind that has been seen at the Drill Hall (gold medal). Mons. L. Linden, Brussels, arranged some magnificently grown *Odontoglossums* (silver Flora medal).

Certificates and Awards of Merit.

Asparagus Sprengeri variegatus (F. Sander & Co.).—The typical *Asparagus Sprengeri* is well known and very highly appreciated, and the varietal name accurately describes the new-comer (first-class certificate).

Odontoglossum crispum aureum rosefieldiense (de Barri Crawshay).—A beautifully formed variety that is almost wholly yellow; practically the only white is on the lower portions of the petals (first-class certificate).

Odontoglossum crispum Pittianum (F. W. Thurgood).—A grand variety; the colour is white, with immense chocolate blotches (first-class certificate).

Odontoglossum crispum tessellatum (L. Linden).—A small but beautifully coloured variety. The ground is white, with superb brown markings (award of merit).

Rhododendron Directeur Rodigas ((J. Veitch & Sons).—A charming variety with salmon pink flowers, borne in good trusses. There are numerous brown spots on the upper portions of the flowers (award of merit).

FIG. 108.—DEUTZIA LEMOINEI. (See page 399.)

Camellia Devonia (R. Veitch & Son).—A fine single white variety of much merit (award of merit).

Cucumber Ideal (E. Beckett).—A medium-sized, straight, dark green fruit with practically no neck (award of merit).

Cypripedium Phæbe (W. M. Appleton).—This is a hybrid from *C. philippinense* and *C. bellatulum*. The dorsal sepal and petals are cream with purple crimson lines, the pouch is dull cream (award of merit).

Geum montanum aurantiacum (A. Perry).—A beautiful orange-coloured variety of a well-known plant (award of merit).

Lælia purpurata Ethel Grey (W. H. Young).—A handsome variety. The sepals and petals are almost pure white; the magnificent lip is rich dark crimson (award of merit).

Lælio-Cattleya Hyeana (J. Veitch & Sons).—This is a bigeneric hybrid from *Cattleya Lawrenceana* and *Lælia purpurata*. The sepals and petals are rich rose purple, and the lip intense crimson purple (award of merit).

Rhododendron Coombe Royal (R. Veitch & Son).—A handsome Himalayan hybrid. The colour is delicate blush, with sparse crimson spots (award of merit).

Tulipa Borszczowi (Miss Willmott).—A most attractive species. The inner colour of the flower is bright yellow, as is the reverse of the inner segments; the reverse of the outer segments is brick red (award of merit).

Tulipa Kolpakowskiana (Miss Willmott).—A brilliant glowing scarlet flower of peculiar attractiveness (award of merit).

Tulip Hector (Hogg & Robertson).—A superb variety with large flowers of the greatest substance. The colour is that of Pond's Seedling Plum edged with gold (award of merit).

Tulip Pink Beauty (Hogg & Robertson).—A grand early variety. The large flowers are bright red and white (award of merit).

Turnip Carter's Early Forcing (E. Beckett).—A handsome, long, pure white variety of first quality (award of merit).

Notes on the Chiswick Trials.

MR. ARTHUR SUTTON writes as follows: It may not be inopportune, when the question of a new Chiswick is occupying the attention of the Fellows of the Royal Horticultural Society, to ask you to find a space in this week's issue of the *Journal of Horticulture* for the accompanying notes on the Chiswick trials. These notes I communicated, with the consent of the president, to each member of the council in March last, and Sir Trevor Lawrence then suggested that there would be no objection to my publishing them if I cared to do so.

For the last twenty years I have taken a personal interest in these trials, and have had ample opportunity of watching them both as a member of the Fruit Committee and as an ordinary Fellow of the society. My connection with horticulture alone would be sufficient inducement to keep myself in touch with the various trials conducted at Chiswick from year to year.

I have therefore been able to appreciate the conscientious work done both by the officials at Chiswick, and those members of the Fruit Committee who have attended the meetings at Chiswick, and in any remarks I may make I wish very clearly to say that I am sure they have, one and all, carried out the tasks allotted them as ably as the circumstances of the case permitted.

I am confident, however, that all those members of the seed trade who have themselves devoted much time to raising novelties or testing novelties on a large scale, would agree with me that in recent years no series of trials at Chiswick of vegetables has been so complete as to warrant the committee in awarding a certificate to any so-called new variety on the ground that it is distinct from or superior to existing varieties. I know this will seem a very sweeping assertion, but at the present moment, when it is suggested that new gardens should be acquired for the purpose of continuing these trials, I think it essential this fact—if it be a fact—should be brought to the notice of those who have the framing of the society's policy, even at the risk of appearing to press unduly the opinion of one who has only just joined the council.

The reasons for this opinion are:—

(i) In no case do the trials at Chiswick contain anything approaching the number of standard sorts which an experienced seedsman knows to be essential if the superiority of a so-called seedling or novelty is to be accurately gauged.

In the case of Peas, I should myself consider a standard collection of 200 or 250 varieties none too many with which to compare a reputed novelty before taking the responsibility of offering it as new, distinct, or superior.

Again, in the case of Potatoes, the standard or reference collection should contain from 250 to 300 varieties to enable even an expert to adjudicate upon a so-called new seedling submitted for award.

By way of illustration I may take the following figures from my trial book for 1899.

Peas.—Total number of trial rows	684
Including seedlings for examination	288
Including other distinct varieties	155
Potatoes.—Total number of trials	1227
Including seedlings for examination	466
Including other distinct varieties	403

At Chiswick last year the numbers were—

Peas.—Old sorts for comparison	9
New varieties for award	46
Potatoes.—Old sorts for comparison	25
New varieties for award	46

Trials of other vegetables require to be tested in the same complete and exhaustive manner if any definite results are to be obtained. I do not care to refer again to my own trial book, but the following figures give some idea of the amount of labour which would be required at Chiswick if trials of vegetables and flowers were carried out with a view of determining whether so-called novelties or seedlings were superior to those already existing:—

Tomatoes.—Total number of trial rows (including 87 separate varieties)...	243
Lettuces.—Total number of trial rows (composed of 198 rows spring-sown for summer cutting in 94 varieties, and 78 rows autumn-sown for spring cutting in 70 varieties)	276
Cauliflowers.—Total number of trial rows (composed of 164 rows spring-sown for autumn cutting in 57 varieties, and 71 rows autumn-sown for spring cutting in 50 varieties)	235
Onions.—Total number of trial rows (composed of 237 rows spring-sown for autumn use in 62 varieties, and 99 rows autumn-sown for spring use in 50 varieties)	336
Cabbages.—Total number of trial rows (composed of 255 rows spring-sown for autumn cutting in 75 varieties, and 180 autumn-sown for spring cutting in 70 varieties)	435
Broccoli.—Total number of trial rows (including 46 separate varieties)...	157
Dwarf and Runner Beans.—Total number of trial rows (including 136 varieties, of which 40 are not yet in commerce)	255
Broad Beans.—Total number of trial rows (including 35 varieties)	85
Asters.—Total number of trial rows (including 270 varieties)	367
Stocks.—Total number of trial rows (including 161 varieties)	187
Sweet Peas.—Total number of trial rows (including 220 varieties)	253

(ii.) Secondly (and I wish to say it with all courtesy to those who form or have formed the Fruit Committee) it is practically impossible for the committee, as a body, to be possessed of the requisite technical or expert knowledge to enable them to judge accurately.

Even those who are practical gardeners have never grown or seen growing in private gardens anything like all the varieties in commerce, and cannot therefore know personally the comparative merits of so-called novelties. I think I am within the mark in saying that a gardener in even a large establishment seldom grows more than fifteen to twenty-five varieties of Peas. Besides this, a gardener generally (not universally) contents himself with the varieties offered by one seedsman, and knows but little of those offered by the many others in the trade.

Unless the members of the committee were almost daily inspecting the trials of the larger seed houses, where for the necessities of the trade it is essential that all existing sorts should from time to time be tested, and where the Pea trials number from 500 to 1000 rows, they could not obtain the technical knowledge required.

(iii.) Thirdly, because it is not sufficient to visit trials two or three times during the season. To ascertain the comparative merits of new and old varieties, Pea trials need to be closely watched day by day, from the day they bloom until after they are matured, a period of six to eight weeks elapsing between the earliest and latest sorts, according to the character of the season. And what is true of Peas is true more or less of other vegetables.

(iv.) Because only comparatively a small number of the committee can find time to go to Chiswick even two or three times during the season.

It may then fairly be asked why, if such is the case, have none of those most intimately concerned ever called the attention of the council to the doubtful utility of these trials?

I can only suppose that it was felt that the council might not readily give up what was generally supposed to be a valuable part of the society's work; also that Chiswick existed, and it was supposed to exist for these trials (and other purposes), and having their own trials conducted at very great outlay of money, time, and energy, it would appear ungenerous to call in question the self-denying work of very able men.

For myself, I may say that it is only the proposal to move to another spot where similar trials would be conducted, and where the committees could only attend with still greater inconvenience, that has led me to express my views.

I have gone thus fully into the details of various trials in order to explain my reasons for thinking that the Chiswick trials do not and could not, as at present carried out, confer any real benefit on horticulture, or at any rate no benefit commensurate with the annual cost—about £1400. If the present garden is retained, or a "new Chiswick" acquired, I would suggest that, instead of comparative trials, standard collections of the leading vegetables and flowers should be grown, so far as space and funds permit, for the interest and information of the Fellows. I do not, however, forget that the gardens exist for other purposes besides trials of vegetables and flowers, but I am not at all sure that the collection of fruit trees, Vines, &c., is so complete and up to date as to be a reliable guide to Fellows wishing to learn the best sorts for planting.

Iris fimbriata.

ALL the Irises possess special attraction for plant admirers, and though many are more showy than fimbriata, yet this has a graceful habit, and is so floriferous that it can be employed with good effect in several ways. Like numerous other members of the family its flowers are, however, somewhat fugacious, and are not adapted for cutting. The plant is compact in habit, and is consequently well suited for culture in pots, and being rather tender is safer in a greenhouse than outside—in fact comparatively few positions suit it except in the warm southern and western counties, where I have occasionally seen it tried, but not with very encouraging results.

For some years I have grown it entirely for greenhouse decoration, and as I have a good stock by forwarding some and retarding others, I manage to maintain a fairly long succession of flowers. These (fig. 109) are of such a soft pale bluish mauve, relieved by orange markings, that they appear very distinct arranged with other plants having more brightly coloured flowers. A moderately light loam, ample root space, and plentiful supplies of water during growth and flowering are the chief points in its culture, and require special attention.—A.

National Auricula Society, Northern Section.

May 4th.

THE annual exhibition was held in the Coal Exchange, Manchester, on Friday, May 4th. The date chosen for the show was perhaps, on the whole, the best that could have been selected, for although the edged varieties would have been better with a few days' more growth, the quality of the selfs, Alpines, and Polyanthus left little to be desired. The exhibitors were, with the exception of Mr. A. Brown, of Birmingham, all northern growers, and they turned up in good numbers. The competition in the Alpine classes was very keen, but edged Auriculas were not well shown, as, with the exception of those staged by Mr. Lord, of Todmorden, they seemed to be a full week short of their best. It is hard to say how this comes about, for Todmorden cannot be considered an early locality. What Mr. Lord's secret is one can only guess, but there is little doubt that if the superb varieties raised by Messrs. Horner and Simonite were procurable, Mr. Lord would provide us with a floral treat that we should remember a very long time.

There are, however, signs that others can raise Show Auriculas besides Messrs. Horner and Simonite, and it was pleasing to see Mr. Lord's green edged seedling Abraham Barker in even better form than last year. It has now won the premier two years in succession. Mr. Midgley also showed a most promising seedling self, with almost all the properties of a first-rate variety. Mr. Horner was represented chiefly by seedlings, of which may be mentioned Waterfly, a large and handsome white edge, but sadly rough as shown, probably through being too young, as one pip was flat enough; Lysander, a magnificent green edge; Eurydice, an almost perfect black self; Red Rover, a fine red self; Ossian, green edge; Orient, a perfect model of a green edge, but shown too young; Favourite, a grand dark purple self; Dryad, a nearly black self; Melanie, deepest brown self, but not flat enough as shown; and Gauntlet, a grand dark red self of exquisite shape and proportions, perhaps the finest self ever raised; if it has a fault it is that the anthers are insignificant, causing the tube to look a little too naked. Miranda, shown by Mr. Simonite, was a white edge short of body colour, giving the flower a wan and ghost-like appearance. Cleopatra is a pleasing self of a novel plum-purple colour, a seedling of Mr. Simonite's. Achilles, a bold and handsome green edge, but like many other large growing sorts not without faults, was well shown by Mr. Gorton. Mr. Midgley had, besides the selfs mentioned, a seedling green edge, which was well grown and with some good properties, but the paste was too narrow, and the flower too much cupped to ever make a first-class variety it is to be feared. Mr. Midgley also showed a white edge seedling, very large and fine but rather rough.

It was fortunate that there were so many novelties to take one's attention, for the older varieties were mostly far from good. Geo. Lightbody, Geo. Rudd, and Acme were perhaps the best. In Alpines there were many good things, among which may be mentioned Dr. Durnford, Pluto, Nonesuch, Cecil Rhodes, Prince Charlie, Patience, Beauty, and one or two of Mr. Gorton's seedlings. It is to be regretted that the Auricula Society have never formulated rules for judging Alpines, and as a consequence everything depends upon the personal inclinations of the judges, whether one is high or low in the prize list. For instance, there is the exhibitor who brings enormous plants, each carrying ten or twelve pips of large and more or less rough flowers; and there is the grower who shows smaller plants, with perhaps only five medium sized pips, but flat and well proportioned; and the question is, which of these is to win? Mr. Lord certainly solved the problem by combining both size and quality, but it was not pleasant to see the refined exhibits of Messrs. Gorton and Brown relegated to obscure places by plants whose chief recommendation was size and good growth. Another matter that should be mentioned is the fact that some exhibitors seem to forget that Alpines should be shaded, and it would be well if they discarded such varieties as Dr. Knott and Emir, for handsome as these varieties are, they do not possess this important property.

In Polyanthus the chief thing of note was that they all came from Middleton, Lancashire, and that there were growers there who could still produce good seedlings; but why should Middleton have the monopoly of Polyanthus? The judges, Messrs. Mottershead & Geggie, of Sale, Cheshire, made the following awards:—

SHOW AURICULAS.

Class 1. *Six dissimilar Auriculas*.—First, Mr. T. Lord, Todmorden, with Rev. F. D. Horner, Abraham Barker, Mrs. Dodwell, Acme, George Lightbody, and Mrs. Potts; second, Rev. F. D. Horner, Burton in Lonsdale, with Shirley Hibberd, Rev. F. D. Horner, Lysander, Red Rover, Eurydice, and Waterfly; third, Mr. W. M. Shipman, Altrincham, with Rev. F. D. Horner, Abbé Liszt, Heatherbell, Beauty, Ruby, and Mrs. Potts; fourth, Mr. J. W. Bentley, Middleton, with Rev. F. D. Horner, Hibernia, George Rudd, Acme, Gerald, and Red Perfection.

Class 2. *Four dissimilar Auriculas*.—First, Mr. Lord with Rev. F. D. Horner, Mrs. Potts, Geo. Lightbody, and Acme; second, Mr. W. H. Midgley, Halifax, with Geo. Lightbody and three seedlings; third, Mr. B. Simonite, Sheffield, with Dinham, Ossian, Miranda, and seedling; fourth, Mr. W. M. Shipman, Altrincham, with Dr. Kidd, Abbé Liszt, Geo. Rudd, and Mrs. Potts.

Class 3. *Pairs of Auriculas*.—First, Mr. T. Buckley, Staleybridge, with Geo. Rudd and Acme; second, Miss Woodhead, Halifax, with Rev.

F. D. Horner and Acme; third, Mr. R. Gorton, Eccles, with Achilles and Ruby; fourth, Mr. B. Simonite with Heatherbell and Cleopatra; fifth, Mr. W. Kershaw, Ashton-under-Lyne, with Heatherbell and Rev. F. D. Horner; sixth, Mr. J. Stelfox, Staleybridge, with Heatherbell and Sapphire; seventh, Mr. A. R. Brown, Birmingham, with Acme and Ruby.

Class 4.—No exhibit.

Class 5. *Single Green Edges*.—First, Mr. Lord with Abraham Barker; second, Rev. F. D. Horner with Orient; third and fourth, Mr. Lord with Rev. F. D. Horner and Mrs. Henwood; fifth, Rev. F. D. Horner with Shirley Hibberd; sixth, Mr. Gorton with Achilles; seventh, Mr. Simonite with Ossian; eighth, Mr. Gorton with J. Hannaford.

FIG. 109.—IRIS FIMBRIATA.

Class 6. *Single Grey Edges*.—First and second, Mr. Lord with Geo. Lightbody and Geo. Rudd; third, Miss Woodhead with Rachel; fourth, Mr. Lord with Richard Headly; fifth, Mr. Gorton with Lancashire Hero; sixth, Mr. Bentley with Dr. Kidd.

Class 7. *Single White Edges*.—First, second, third, fourth, and fifth, Mr. Lord with John Simonite, Traill's Beauty, Mrs. Dodwell, Acme, and Elaine; sixth, Miss Woodhead with Smiling Beauty; seventh, Mr. Lord with Heatherbell; eighth, Mr. Simonite with Miranda.

Class 8. *Single Selfs*.—First, Rev. F. D. Horner with Favourite; second and third, Mr. Lord with Mrs. A. Potts and Gerald; fourth, fifth, and sixth, Rev. F. D. Horner with Dryad, Melanie, and Gauntlet; seventh, Mr. Simonite with Cleopatra.

Premier Auricula of the whole show.—Mr. Lord with Abraham Barker.

ALPINE AURICULAS.

Class 9. *Six dissimilar*.—First, Mr. Lord with Dr. Durnford, Pluto, John Ashton, Bright Eyes, Judith, and Patience; second, Mr. Beswick (Middleton), with Nonesuch, John Allen, Dr. Durnford, John Ashton, Dr. Knott, and a seedling; third, Mr. Stelfox with Dr. Durnford, John Allen, John Ashton, Forest Queen, Bright Eyes, and seedling; fourth, Mr. Brown with A. W. Jones, Mrs. Martin Smith, Mabel, W. L. Walker, Winifred, and J. J. Keen; fifth, Mr. Wood with Dr. Durnford, Dr.

Knott, John Ashton, Emir, John Allen, and Forest Queen; sixth, Mr. R. Gorton with Miranda, Sweet Lavender, Cecil Rhodes, Mrs. Barnett, Dreadnought, and Dean Hole.

Class 10. *Four dissimilar Alpines*.—First, Mr. Lord with Dr. Durnford, John Ashton, Patience, and Pluto; second, Mr. Beswick with Bright Eyes, Nonesuch, John Allen, and John Ashton; third, Mr. Puckley with Dr. Knott, John Ashton, Dr. Durnford, and Bright Eyes; fourth, Mr. Stelfox with John Ashton, Bright Eyes, John Allen, and seedling; fifth, Mr. Gorton with Sweet Lavender, Cecil Rhodes, Prince Charlie, and Miss Shaw; sixth, Mr. Bentley with Mrs. Martin, Bright Eyes, Dr. Durnford, and John Allen.

Class 11. *Pairs of Alpines*.—First, Mr. Bentley with Dr. Durnford and Bright Eyes; second, Mr. Buckley with Dr. Knott and Evelyn Phillips; third, Mr. J. Goodier, Middleton, with Dr. Durnford and John Allen; fourth, Mr. W. Stringer, Middleton, with Dr. Knott and Bright Eyes; fifth, Mr. G. Thornley, Middleton, with seedlings.

Class 12. *Pairs of Alpines* (maiden growers).—First, Mr. Goodier with Dr. Durnford and John Allen.

Class 13. *Single Yellow Centres*.—First, Mr. Gorton with Prince Charlie; second, Mr. Lord with seedling; third, Mr. Beswick with Dr. Durnford; fourth, Mr. Lord with John Allen; fifth, Mr. Gorton with Seedling 91; sixth, Mr. Stelfox with seedling.

Class 14. *Single White Centres*.—First, Mr. Lord with Patience; second, third, and fourth, Mr. Beswick with Beauty, John Ashton, and seedling; fifth, Mr. Lord with Exonian; sixth, Mr. Gorton with Seedling 118.

Premier Alpine in the exhibition.—Mr. Lord with Pluto.

POLYANTHUSES.

Class 15. *Three black ground Polyanthuses, dissimilar*.—First, Mr. Beswick with Mrs. Brownhill, Tiny, and Exile; second, Mr. Stringer with Trilby, Tiny, and Mrs. Brownhill; third, Mr. Thornley with Mrs. Brownhill, Exile, and Cheshire Favourite; fourth, Mr. T. Oldham with Trilby, Tiny, and Mrs. Brownhill.

Class 16. *Three red ground Polyanthuses dissimilar*.—First, Mr. Thornley with Middleton Favourite, George IV., and Sidney Smith; second, Mr. Beswick with Middleton Favourite, William IV., and seedling; third, Mr. Stringer with Middleton Favourite, Sidney Smith, and William IV.; fourth, Mr. Oldham with Middleton Favourite, Sidney Smith, and seedling.

Class 17. *Single Plants, Black Grounds*.—First, Mr. Beswick with Mrs. Brownhill; second, Mr. Oldham with Tiny; third, Mr. Thornley with Cheshire Favourite; fourth, Mr. Oldham with Trilby; fifth, Mr. Thornley with Exile.

Class 18. *Single Plants, Red Grounds*.—First, second, and third, Mr. Thornley with George IV., Middleton Favourite, and Seedling; fourth, Mr. Beswick with Seedling; fifth, Mr. Stringer with Sidney Smith.

Premier Polyanthus in the exhibition.—Mr. W. Stringer with Mrs. Brownhill.—JAMES W. BENTLEY.

The Young Gardeners' Domain.

Begonia Gloire de Lorraine.

THIS beautiful Begonia is very useful for winter flowering, and makes a grand display for quite three months when arranged amongst other plants in the flowering house. It looks very effective when grown in baskets suspended from the roof of a plant house, and it is also useful for table decoration when used with spikes of Dendrobium Phalaenopsis Schröderianum or Calanthe Veitchi, lightly arranged above. B. Gloire de Lorraine may be propagated from cuttings, several of which can be placed round the edge of a 4-inch pot, in good sandy soil, and plunged in a propagating case with a good bottom heat, where they will soon take root. They can also be propagated from leaves placed edgewise in pans of sandy soil plunged in a good bottom heat. The pans should be covered with sheets of glass, these being turned over every day to let the condensed moisture escape, as if this is allowed to drip on to the leaves it often causes them to decay.

When the cuttings or young plants are well rooted they should be placed into 3-inch pots, using a compost of peat, loam, leaf mould, and silver sand in about equal parts, and then be placed on a shelf in an intermediate house. Watering must be very carefully attended to. When the plants are well established in these pots they ought to be transferred into clean well drained 5-inch pots. The plants should be neatly staked with small green stakes, using six or eight in each pot, as they well repay a little extra trouble in this respect. If specimens for suspension are desired, four plants may be placed in a basket or large Orchid pot, three near the edge of the basket or pot, and allowed to hang naturally round the sides; the other plant should be placed in the centre and neatly staked.

Before flowering the plants ought to be kept in a moist intermediate temperature, where they will get plenty of light, but be shaded from the direct rays of the sun. When flowering they should be placed in rather a cooler and drier temperature to prolong the flowering period. Liquid manure and clear soot water may be given with advantage about twice a week.—F. W. P.

Hardy Fruit Garden.

Mulching Fruit Trees.—The practice of mulching fruit trees has many advantages. It prevents rapid evaporation from the soil of much valuable moisture during hot, dry weather, and tends to keep the roots cool in consequence. When moisture is available in the surface soil the fine roots will remain there instead of descending to a lower level. The character of the subsoil may prove inimical to the welfare of the roots if they pass into it in search of moisture. Hence the chief advantage of mulching lies in keeping the roots ramifying near the surface. Weakly trees are benefited, also trees bearing crops, especially when the burden is heavy.

When to Mulch.—During cold, wet periods in winter and spring it is obvious that a thick coating of manure over the roots of young fruit trees, especially in heavy, clayey land, is not conducive to healthy growth, and should be avoided. The best period for laying on a general mulching is in May, when the soil has naturally become warmed by the sun. Mulching young fruit trees immediately after planting is not always good unless the proper material is used. Winter dressing with decomposed manure is good for old trees, but cannot be recommended for young trees, as it naturally prevents the soil becoming warmed because of its close texture. Perhaps the best time to apply it is immediately after a good rainfall in May, at which time the soil is both warm and moist. Immediately following a copious watering is also a suitable time, more especially in the case of wall trees, as the soil over the roots is so fully exposed to drying influences. Light soils need mulching sooner than heavy ground.

Material for Mulching.—For trees well established and bearing good crops the mulching will not only conserve moisture but contains fertilising matter that the rain or artificial waterings will wash into the soil. Short, decomposed manure is, therefore, good for these, and also for weakly trees needing some assistance to impart vigour; vigorous young trees do not require stimulation at the roots, yet need some material to insure the soil being kept in a medium state of moisture. Littery manure will effect this, preventing the escape of surface soil moisture in light soils, and cracking of the surface, common on heavy ground. If the soil round young trees cannot be mulched with manure from various causes, the next best thing to do is to maintain the surface loose with the hoe. Short, lumpy material forms a good medium for mixing in any artificial fertiliser for the benefit of the trees, and also assists in distributing economically applications of liquid manure or water. The mulch should extend as far as the roots spread out from the bole.

Mulching Strawberries.—Strawberries in a fruiting condition should always be mulched at this season with a mixture of short and long manure. Liquid manure can be poured over the mulching around the plants, and it will assist the fruit to develop. On light and shallow soils a mulching will be beneficial even to young plants.

Apricots.—A preliminary thinning may be given to the trees as soon as the fruit has attained to the size of horse beans. All the worst-placed fruit should first of all be removed, and those which are improperly fertilised known by their backwardness in swelling. Also shorten foreright shoots not wanted to lay in to three leaves, and cut out entirely ill-placed growths. This timely attention at frequent intervals results in the trees being kept well regulated as to growths and the fruit well proportioned. Vigorous trees may be allowed to carry the most fruit. Give the final reduction after the stoning period, which is a critical time.

Peaches and Nectarines.—Cutting out ill-placed shoots is still an essential operation. Lay in the successional bearing shoots in the proper direction. When disbudding leave a growth above the fruit in order that sap may be attracted through the shoot, some of it being diverted to the fruit. Commence to thin the fruit early, removing the inconveniently situated as soon as possible. The border containing the roots often becomes dry quickly at this season, hence to insure the fruit swelling regularly fortify the soil with moisture and food.

Training Young Fruit Trees.—The chief care just now in managing young specimens, either on walls or in the open, is to see that growths or shoots are being formed in suitable positions for forming the main branches. Secure growths as near as possible at regular distances apart, and train them in the desired direction, equalising the vigour of trees by the simple expedient of depressing luxuriant shoots, and training weak growths in a perpendicular direction. This is, of course, only temporary, and when the desired end is secured lay in the shoots in their proper positions. While retaining and encouraging the principal shoots some attention must be given to removing superfluous and crowded growths or stopping extensions. Trees liable to insect pests should be well syringed on warm afternoons. This will tend to keep down such, and at the same time encourage good growth. Lateral shoots starting from the main branches of wall trees should be shortened at the fifth or sixth good leaf.

Fruit Forcing.

Cherry House.—The Cherries, now ripening rapidly, must be kept dry, but the surface of the borders should be damped with the syringe occasionally, air being admitted constantly, or condensation will seriously affect the fruit. The moisture of the border is apt to be miscalculated by the syringing keeping the surface damp, hence it should be examined and water supplied to keep the soil moist down to the drainage. Tie in the shoots as they advance, and stop those required to form spurs at about the fifth leaf, pinching sub-laterals to one joint. Black aphides must be kept under by dipping the shoots affected in tobacco water, gently rubbing them with fingers, or their shining bodies will throw off the decoction and escape. Ventilate freely on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to insure a circulation of air. Netting will be necessary over the ventilators to prevent birds attacking the Cherries. Trees in pots should be well supplied with water.

Cucumbers.—Plants in bearing all the winter will now be showing signs of exhaustion, and had better be removed and their places filled with others without delay. Assist young plants which show signs of weakness by removing the staminate flowers and the first fruits, stopping at every third or fourth joint, removing all weakly superfluous growths. Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially for houses facing south, but shade only to prevent flagging. Houses with the roof-lights facing east and west will not require shading, or only in the afternoon. Little or no fire heat will be required by day, shutting the valves about 8 A.M., and opening them again about 4 P.M., or later, keeping a good moisture by damping the floors.

In Pits and Frames.—Sow seed to secure plants for placing in pits and frames, a fair amount of bottom heat being necessary, which is secured by using the less decomposed material from exhausted hot-beds, with about a fourth of fresh material. Ventilate moderately if the weather is cold, and close as early in the afternoon as safe, running up to 90° or more, and employ night coverings. Attend to the linings with a view to maintain good bottom heat, but be careful to avoid rank vapour.

Peaches and Nectarines.—*Houses Started at the New Year.*—The fruit is about completing the stoning process, but it must not be subjected to a higher temperature than 60° to 65° by artificial means, commencing to ventilate at 65°, and not allowing 75° to be exceeded without full ventilation. If the fruits are too numerous remove the smallest, allowing one fruit to each square foot of trellis covered with foliage, leaving them a little closer on strong wood, and less on the weaker. By apportioning the crop to the vigour of the parts of a tree the evenness of the growths may be maintained. Tie the shoots as they advance, removing the superfluous growths, as it is important no more be retained than can have exposure to light and air. Draw the leaves aside or even shorten them so as to expose the fruit to light, raising such as require it on thin laths placed across the wires of the trellis with their apices to the sun.

After stoning maintain a good moisture in the house, and water the inside border copiously, which in well-drained soil will be required about once a week, mulching the surface with about an inch thickness of short, rather lumpy manure. If the fruit is not required ripe as soon as practicable, continue 60° to 65° as the night temperature, 65° artificially by day in dull weather, 70° to 75° with sun heat, closing at the latter with plenty of atmospheric moisture. In a high night temperature of 70° to 75° by artificial means, 80° to 85° or 90° from sun heat, and moist atmosphere. Peaches swell to a great size after stoning, but they are not usually so high-coloured or so well flavoured as those ripened in less heat and moisture, and with free ventilation.

Houses Started Early in February.—The fruit, being in the early stages of stoning, should be reduced to two on strong shoots and one on the weaker, not leaving too many, for there is danger of their not stoning in that case, while they will be small if they should stone. Retain in all cases the fruit best situated for receiving air and light. Thin the shoots where crowded, pinching laterals to one leaf, and secure the growths to the trellis as they advance. Syringe the trees twice a day in bright weather, but once only in dull, and not then if the foliage does not become dry before nightfall, or is found dripping with moisture in the morning. The temperature may be kept at 55° to 60° at night, and 60° to 65° by day, ventilating from 65°, and fully between 70° and 75°. Supply water to the roots as required, affording weakly trees and those carrying heavy crops top-dressings of chemical manure occasionally, say every fortnight or three weeks, washing them in moderately, or afford liquid manure alternately with the waterings.

Trees Started in March.—Thin the fruit now that it is swelling freely, and choice can be made of the most promising for the crop. Reserve those on the upper side or front of the trellis, two or three on strong shoots will be ample to leave, and proportionately fewer on weaker growths. Remove all superfluous shoots gradually, retaining those only for attracting the sap to the fruit, which stop at two or three good leaves, and those from the base of the present bearing wood for furnishing fruit another year, with such extensions as are necessary. Train the growths as they advance, securing them loosely to the trellis. Afford liquid manure to such as require more vigour, but avoid stimulating vigorous trees too much, as that will encourage wood at the

expense of the fruit stoning. Keep red spider under by syringing, and if aphides or other pests appear promptly apply an insecticide, those advertised being thoroughly efficacious and safe, provided the instructions are carefully followed.

Late Houses.—The fruits being well set, the trees will need syringing in the morning and on fine afternoons to rid them of the remains of the flowers. Commence thinning when the fruits are the size of horse beans, removing the smallest and worst placed, leaving a few more only than will be required for the crops, but regard must be had to the vigour of the trees, and their liability or otherwise to cast some of the fruit in stoning. Disbudding and laying-in the shoots should be carefully attended to, doing the first gradually, and the latter with due regard to the swelling of the shoots. A temperature of 50° at night and 55° by day artificially will be sufficient to keep the trees in steady progress, ventilating freely above that, unless it is desirable to hasten the crop, when a temperature of 55° at night and 60° to 65° may be secured, with 70° to 75° from sun heat, ventilating from 65°.

Unheated Houses or Wall Cases.—The fruits have set well, very many more than the trees can bring to a full size, and they should be thinned as soon as the best can be decided upon by their taking the lead in swelling. Overburdening the trees in the early stages of the fruit swelling prevents their making wood for another season's crop, while excessive disbudding may cause the fruits to fall, or a strong growth to be made. A moderate syringing on fine mornings will be of great assistance in ridding the trees of the remains of the blossoms, but afternoon syringings are not advisable; nor sprinklings that are likely to cause a moist atmosphere at night, as the weather is not yet to be depended upon, and a severe frost occurring while the trees or house is damp is very much more likely to prove disastrous to the crop than if the atmosphere be dry. Ventilate at 50°, not allowing an advance above 65° without full ventilation, and close at 50°, or before if there is a prospect of frost at night. If water be necessary, apply it sufficiently early in the day to allow of the surface becoming fairly dry before the house is closed.

THE BEE-KEEPER.

Young Queens.

It is a recognised fact that bee-keepers who have studied the requirements of their bees, and who endeavour to obtain as much honey as possible, have a system of rearing young queens. There is no comparison between a stock headed by a worn-out queen and a colony having a young queen reared from a good strain. In the former case it is doubtful whether a surplus will be stored. But in the latter instance a rich harvest will be obtained if ordinary care is taken and the weather is favourable.

Bearing these facts in mind, it is surprising the amount of ignorance one often finds among the rural classes in various parts of the country. During a recent visit to the New Forest, where the early spring flowers were much in advance of the midland and northern counties, we saw numerous colonies of bees, the majority of them being in straw skeps. In conversation with several bee-keepers we learnt the bees were left very much to chance, and no system of queen rearing was attempted. We found more often than otherwise that the bees were placed over the sulphur pit to obtain honey in the autumn. It, however, shows how necessary it is that bee-keepers should do all in their power to assist those who are not so favourably situated. There are probably more queenless stocks at this season than at any other time of the year. The reason is not far to seek. Owing to a variety of causes young queens may not have been reared the previous season. Some of the queens may be in their third year, and have passed through the winter safely and well; they are, however, unable to fulfil their duties in the hive. If they do not succumb, the bees will take steps to replace them by starting queen cells; at the same time some drone brood will be found in the hive. During the past week we have examined a stock in this condition. The bees only covered two frames; there were a few square inches of worker brood, and about twenty drones just sealed over. We concluded this was a certain sign that the stock would soon be queenless. They were therefore united to the next colony. The queen's wings were ragged, which is a sign of old age.

System in Rearing Queens.

The operation of rearing young queens is not nearly as formidable as a novice would imagine. There are so many ways of doing it, and if worked on the right lines there need be no difficulty in carrying it out successfully. It is too early to commence operations, but it is as well to make arrangements, so that when the time comes there will be no delay. Queens are at their best the second year. It is as well therefore to have as many at that age as possible. Thus queens hatched during the coming summer will be at their best next year.

Bearing these facts in mind, we endeavour to have as many stocks as strong as possible by the time the honey flow comes. If several queens are required, a strong stock is selected from which to obtain them, the queen being removed. The combs containing freshly laid eggs should have small holes bored through them, or be notched at the bottom. Close the division board and allow them to remain for a few days. An examination should then be made, when there will probably be from twelve to twenty queen cells formed. If by any chance there are not as many formed as will be required, insert a frame of newly laid eggs taken from another hive, and fresh queen cells will be started. Queens are hatched in sixteen days from the laying of the egg. Three or four days previous to this divide the stock into as many nuclei as are required. If other colonies have been weakened by the removal of brood and bees for strengthening other stocks for extracting purposes, the queens may be removed and a queen cell given to each colony. After the young queens have become fertilised they may be introduced to other colonies.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Malope splendens (J. H.).—This is a sub-variety of *Malope trifida grandiflora*, with very fine bright flowers of crimson shade. The plant is of a sturdy, branching habit, and in good soil attains to a height of 2 to 3 feet. It is an annual, and succeeds in the open border if sown at the end of April or early in May. The plant is of easy culture in almost any ordinary garden soil, but succeeds best in a sandy one, and in a sunny situation.

Grafting Epiphyllums (M. G. R.).—Grafting is readily effected by pulling out a short branch just as growth commences in spring, making a slanting cut in the stock downwards, and then forming the Epiphyllum branch into a wedge so as to fit the cut in the stock. Insert it and secure it with one of the sharp spines of the *Pereskia* stock passed right through to hold it firmly. The graft may also be inserted on the top of the stock. No covering is necessary; the plants should be in a warm, moist atmosphere, and care must be taken to properly secure the grafts with the *Pereskia* spines.

Marechal Niel Rose Buds Dropping (Amateur).—The fact of your having been in the habit of applying manure water twice and three times a week plainly accounts for the dropping of the buds and decaying of the edges of the leaves. Although this class of Rose, when established and the roots are in a healthy condition, will derive great advantage from an occasional use of stimulants, they certainly will not bear with impunity such frequent doses as you have been in the habit of giving yours. Stimulants should only be given once a week when the plants are carrying a crop of buds, and this must vary in strength according to the age, size, and time the plants have been established. Cease the application of liquid manure for a time, remove all the unhealthy looking buds at once, and encourage the plant to make new growths by syringing the foliage once or twice a day. A good and safe stimulant for Roses is an ounce of guano dissolved in a gallon of soft water, and applied once a week when the plant is in flower.

Liquid Manure for Roses (*Idem*).—1. If your Rose trees are growing strongly, and in rich soil, it is advisable to wait until the flower buds are beginning to form before supplying liquid manure to them; but in the case of those growing in soil not often enriched with manure, a weekly supply will do good. In all cases the liquid manure should be fairly diluted with water before its application. When the buds are formed, twice a week will not be too often to apply the liquid manure.

"Blind" Apple Tree Buds (*Loughgall*).—The twigs are quite sound in the bark and woody tissues, but the greater part of the buds are "blind," brown and dead. Some of the buds have pushed growth, the inner or apical leaves being browned and distorted, and the outer or more developed ones partly blackened as by frost. On examining the buds the tissues were found in a granulated state and occupied by the mycelial hyphae of a fungus, but whether saprophytic or parasitic in nature is undeterminable in the absence of "fruits." Similar result attended the examination of the distorted leaves, there being no out-growths. The affection is solely confined to the buds and the young growths. Possibly the heavy crop last year has so impaired the tree's health as to result in imperfect bud formation, thus rendering attack by malignant organisms more disastrous. The fungoid bodies closely resemble those of brown rot fungus, *Monilia fructigena*, but we have not noticed it before on Apple tree buds. There is no trace of insects, only the branching mycelium of the fungus, which will probably yield to spraying with dilute Bordeaux mixture. Spray first before the blossoms open, then as soon as the fruit is well formed spray again, and repeat the application twice later at intervals of two weeks.

Tulips not Perfecting Their Flowers (*Charing Cross*).—The two plants arrived in good condition for examination, and appear of the variety you name—*Couleur Cardinal*. The flowers were dried up in a partially developed state, being very small, and in the condition known to growers as "deaf." This has been attributed to a sudden check when the flowers were in the bud state, such as a quickly occurring and considerable depression of temperature, but though this may be the cause in some cases, we usually find that it arises from an imperfect formation of the flower buds in the previous season, either from over-propagation or indifferent growth and maturation of the plants. There may be, and no doubt are, other causes of the "deafness," such as attacks of root mites, which impair the vitality of the bulbs at the base and pass from these to the roots, destroying them when partly developed, thus depriving the flowers of the support essential for their development. On one of the bulbs there were traces of root or bulb mite, and in both instances the roots of the plants were few and dead. This we attribute to the indifferent condition of the bulbs, as induced by the imperfect growth and maturation in the previous year.

Repotting Indian Azaleas (*Inquirer*).—The best time to repot Azaleas is directly after the flowering period is over, as it is then when both top and root growth is most active. As a rule, every third year is often enough to give larger pots. Azaleas can easily be over-potted. Supposing the pots are crowded with roots turn them out, carefully remove the drainage, and with a pointed stick lightly loosen the sides and upper surface of the ball. Shift into clean, well drained pots not more than one inch larger all round. If the roots are in bad condition through over-potting, the action of worms or over-watering which may have led to sourness of soil, reduce the balls rather freely, pricking away much of the unoccupied soil, and place in the same sized or even smaller pots than they were in previously. Use a mixture consisting of two parts good brown fibrous peat, one part of fine leaf soil, and one part of brown fibrous loam, with silver sand freely added. Pot very firmly, taking particular care to well drive the soil down the sides of the pots with a flat potting stick. Keep the plants in gentle heat of from 55° to 60°, shade from bright sunshine, and syringe frequently. Not till the young growths are well matured and the buds really set should the plants be turned out of the house, when they ought to be set on a bed of ashes in a cool position, housing again before frosts can injure them.

Mole Crickets Damaging Seedling Plants (M. C.).—These pests do considerable mischief in gardens, and happily are confined to the south of Britain, not extending to the north. The insect prefers light, sandy, or cultivated soils, especially in damp situations, and in digging its burrows it cuts the roots that it encounters, causing the plants to wither without evident cause. It eats the underground parts, whether roots or stems, of many plants in both gardens and fields, but the favourite food of the mole cricket is insects, and the creature is so voracious that when starved it devours its own limbs. The best means of riddance is to take some pieces of raw meat cut so as to resemble worms, and insert them in the soil, preferably in the burrows of the insects, and partly out of the soil, securing with a piece of bouquet wire to a small stick. The animal may thus be either dug out or pulled out of the soil, a vessel of hot water being at hand to drop those taken at the baits into. The insects are readily killed by hot water, it being a good practice to follow up the runs with the finger till the spots where the creatures rest are arrived at, which are known by the descent and smoothness of the holes, then widen these at the top and fill them to the brims with water at a temperature of 110° to 125°. In the case of plants in rows tread the ground quite firmly and smoothly so that the pathways of the insects may be readily seen. Follow the runs up and fill the holes with hot water.

Spots on Pear Leaves (*Anxious*).—The cause of the spots is the Pear gall mite (*Phytoptus pyri*) in each of which spot there is a small cavity occupied by nearly white four-legged microscopic creatures, or bluntly oval bodies—the primary eggs of the cycle—those found later not being more than “buds,” and are much larger. The spots are very numerous—indeed, run together—but each has a small opening in the under side of the leaf protected more or less by hairs. All are due to the action of the mites, which in bad cases greatly weaken the tree, causing the leaves to turn brown or black and fall prematurely. Probably the safest remedy is bisulphide of calcium made by boiling 1 lb. of flowers of sulphur and 1 lb. quicklime in a gallon of water for fifteen minutes, constantly stirring whilst it is boiling, then allowed to settle, and the clear liquid poured off for use. This placed in a stone bottle and tightly corked in a dark place will keep indefinitely. Dilute with 100 parts of water for use, or say 1 gill (quarter pint) of the liquor to 3 gallons of water, and apply with a syringe, taking care to wet the under side of the foliage, then some will enter the apertures or be held there sufficiently for destroying the mites. The bisulphide solution should be kept off paint, otherwise it will discolour it for a time. Repeat the syringing if necessary, but one application usually suffices to prevent the spread of the infection, though it will not restore destroyed tissues to health.

Pests Destroying Plants in Pots (*White Worms*).—No. 1 pest belongs to the natural order, Oligochaeta, and to the genus Enchytraeus, the species being *E. Buckholzei*, which attacks the root hairs of various plants and sets up disease. As the manure swarmed with the pests, they were thus introduced and fostered. They induce a sour condition of the soil, which quite as much as their attack contributes to the loss of roots. You use the manure and the leaf mould too raw, not reducing the former to a rotten state and the latter into the condition of mould, the processes of disintegration being effected in the soil, and in excess of water resulting in sourness. The other pest, No. 2, is the so-called “pill beetle,” and is popularly known as the Armadillo, *A. vulgaris*. It also lives on living vegetable substances as well as those in a state of decay, the freshness and openness of the material submitted to us accounting for its presence. We can simply suggest a thorough preparation of the compost materials before use. The white worms succumb, as you have found, to Fir tree oil insecticide, lime water, and Jeyes' fluid, but you say these substances injure the roots of the plants. Possibly the first and last named articles have been applied too strong, the lime water not being injurious unless used in excessive amount and to plants that require peaty soil. Woodlice should be trapped; two pieces of old board placed one upon the other with a pebble between, sprinkling a little bran on the lower one, form an excellent trap. This should be examined every morning, and the woodlice brushed into a pail of hot water.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. C. N.*)—*Iris fimbriata*. See illustration and accompanying letterpress on page 402. (*J. K.*)—The specimen is too small for positive identification, but most probably it is *Edgeworthia chrysantha*. (*R. G.*)—*Lathyrus vernus*. (*T. Y.*)—1, *Saxifraga muscosa*; 2, *Doronicum plantagineum*; 3, *Magnolia conspicua*; 4, *M. Soulangeana*; 5, *Prunus Padus*; 6, *Berberis stenophylla*. (*P. R.*)—1, *Berberis Darwini*; 2, *Osmanthus ilicifolius*; 3, dead; 4, *Pteris serrulata*; 5, *Adiantum grandiceps*; 6, specimen insufficient, send fertile frond. (*T. A. J.*)—1, *Chorozema cordatum splendens*; 2, *Anthurium Scherzerianum*; 3, an *Anthurium*, species undeterminable; 4, a Flax, probably *Linum perenne*; 5, a *Megasea*, probably *latifolia*; 6, send fresh specimen.

Lincoln April Fair.

“THE greatest fair in England,” says “Whitaker's Almanack;” and when we consider the fair as a whole, the time it occupies, the variety of customers which it brings together, and the quality of its wares, we think that Whitaker is justified in making the statement referred to.

The great fair takes place during the last whole week of April,

and therefore, technically speaking, began this year on April 23rd, and finished on the 28th; but though the 23rd was the official commencement, and the day on which the city authorities first allowed horses to stand for sale in the public streets, the real, and in some respects the most important business began nearly a week before. On Tuesday, the 17th, horses had arrived, and buyers had preceded them. Business soon became exceedingly brisk, for the war has created an extra demand for medium horses, which has had an influence on both the higher and lower classes of animals. We have heard (but of course it is hearsay) that the deepest depths of some of the inn yards could tales unfold as to Sunday trading; but perchance they are idle tales, and when the yard is spacious and secluded, and the straw bed thick, a gentle exercise canter is almost a work of piety as well as necessity. As many of the early buyers are continental, they at any rate would see nothing wrong in a little pleasant relaxation on Sunday afternoon. That much business was done this year on the 22nd of April we doubt, for many sellers of high-class horses had already sold out and gone home, and so few animals were present unsold that business would cease for want of material.

We have a strong exemplification of the truth of the proverb that "the early bird gets the worm" in the fact that the fair yearly commences a little earlier. Easter and Bank Holiday acted in prevention of this on the recent occasion, but as a rule the buyer who turns up an hour behind his opponent, and therefore misses the chance of valuable bargains, makes careful note of his mistake, and comes earlier next year. *Vice versa* the same occurs the year after, and so on *ad infinitum*, until we wonder how long it will be before Lincoln April Fair commences in March.

The visitors brought to Lincoln by the sheep fair on the Thursday and the beast fair on the Friday come chiefly from Lincolnshire and the neighbouring counties. It is the horse fair which brings people such long distances. This year there were buyers from North and South America, France, Germany, Italy, Belgium, and Holland. A demand for horses for continental military purposes had been anticipated, and large purchases were made by the Governments of Germany, Italy, and France. The prices given by these military authorities were, however, not so high as had been expected, and there was some disappointment, although prices were better than at previous fairs. The horses these buyers required were from 15—1 to 15—3 hands, not under five, or over ten years. Prices were from £35 to £45, with an occasional £50, whilst officers' chargers ranged as high as £60.

Of the high class horses, hunters were not so much in demand as usual, though fair prices were realised for good animals with some reputation. There was an excellent trade for harness horses, and many made high prices, Mr. W. J. Smith of Cadogan Place giving £1000 for six to Mr. Beldam of Witchford, Ely. For cobs and ponies there was also an excellent trade at good prices. Fine draught horses were very scarce and dear, and prices rose considerably during the fair, dealers buying them and reselling; some were resold several times. The following prices will give some idea of the value of the different classes:—

Matched pairs of carriage horses	£150	to	£350
High stepping brougham horses	70	to	140
do saddle horses	80	to	150
Good carriage horses	70	to	120
Troopers, from	35	to	60
Bus and van horses	30	to	55
Cab horses	20	to	35
Ponies	15	to	120
Draught horses for town work	50	to	125
Farm horses	30	to	50

The sheep fair on Thursday was the smallest on record, only 10,000 sheep being penned, as against 15,000 last year, 18,000 in 1898, and 23,000 in 1897. This great falling off this year must have been expected, for few farmers have had many Turnips left since January, and large numbers of hogs were sold to the butchers in early spring which in the ordinary course of things would have been shown at this fair. A firm of bankers offer a cup every year for

the best pen of 100 grazing he hogs. The first prize pen, belonging to Mr. Headland of Potter Hanworth, sold for 70s. each, but afterwards changed hands again at a good profit; the second prize lot, the property of Mr. Maltby of Dunston, who had previously won the cup two years running, made 72s. each, going to a grazier at first hand. In Lincolnshire yearling sheep, which in the south are spoken of as hoggets, are known as hogs, and the males and females as heders and sheders.

Prices for sheep were not much above the average of previous years, many farmers only making about the same as last year, but when the very mean and backward condition of the majority is considered the prices must be looked upon as very satisfactory. We know that many butchers have lately found their mutton cost them 9½d. per pound, and even more, and this shows how scarce are sheep with any meat on them.

Nine years ago was formed the Lincoln Longwool Sheep Breeders' Association. This society is now considered to be the leading sheep breeding society of the world, and we notice in the account of the annual meeting at Lincoln recently that no less than 60,000 lambs were officially earmarked by the society last year, being about 4000 less than during the previous year. It was, therefore, not on account of the shortage of the 1899 lamb crop that this year's sheep fair fell so far below the average in numbers.

The Lincolnshire Red Shorthorn Association held its sixth annual meeting on the Wednesday in fair week, and its annual sale of bulls on the Thursday. About 300 fine specimens of the breed were offered for sale, and almost, if not quite, all found purchasers at prices varying from 15 to 105 guineas. The improvement in the general character of the bulls shown at the sale since the association was formed is remarkable for so short a time.

The beast fair on Friday was about an average one as regards numbers and price, but below average as to quality. Good fresh bullocks were very scarce, and made up to £25 each, but many of the cattle shown were in poor condition, and these met a very slow trade. The better class beasts, which make upwards of £20 each, are chiefly bought to graze and finish on the rich salt marshes which border the Lincolnshire coast.

There is a most varied pleasure fair for sightseers, but few of the people who attend on business bend their steps in that direction when business is done. There are many objects of historical interest in Lincoln, and a few spare hours may be profitably spent in studying and pondering over these relics of bygone days.

Work on the Home Farm.

The weather has been very variable since our last, and has been favourable for farm work. Two sharp frosts did no harm except to the pasture, and a nice rain following a few dry days has done much to aid the drags and harrows in preparing the land for Swedes. Some of the stronger fields are not in a very kind condition, as they turned up very rough when ploughed over lately; the attempt at working them in February apparently did more harm than good. This once more proves how unwise it is for farmers to be too anxious to get work done when weather conditions are unfavourable; it is very seldom that there is any real saving, and more often there is a positive loss.

Wheats are looking well, and they are keeping root fairly, few complaints of wireworm being heard. The plant generally is good, and though backward we think well of the prospects of this crop.

Barleys have grown and come on wonderfully; the heat during the latter end of Easter week having given them a capital start. We have heard many remarks as to the rapidity with which Barley has grown this spring, and this should do much to make up for the late sowing. We hear one or two farmers who drilled early complain of their Barley suffering from grub, but as a rule Barleys look very well. The same may be said for Peas, and also for winter Beans, which never looked better.

Cattle are not making much progress, for there is little grass, and they are still looking thin and backward. There will not be much June beef this year.

Ewes are poor and look very ragged and badly. It is a pity that clipping time is not here, for some of them will soon have little wool left. It might pay to clip early this year if the temperature would allow, for we always notice an improvement in the ewes after they part with their wool, for this latter requires some support, and is only a burden when not needed as clothing. Lambs are doing fairly well, but are much behind their usual condition. Fat ones have never been scarcer or dearer on May 1st.

Late Apples.

HERE seems to be good reason for the belief that many gardens are not so well equipped as they ought to be to meet the demand for Apples in spring. In this respect we appear to have retrograded, for the older race of gardeners prided themselves on maintaining a long supply, not infrequently extending to and overlapping the new crop of the succeeding year. The extensive planting of the numerous fine and large early Apples is, I have no doubt, one great cause of this displacement, but also, I venture to think, the treatment accorded to late varieties; and perhaps, as well, the management of fruit rooms has had not a little influence in contracting the supply of late Apples. Whatever the cause, we ought to waken up and seriously face the question, for there is less reason that now, more than at any previous time, we should fail in this matter. As to amendment there is no fear. The British gardener has shown over and over again his capacity, as well as his willingness, to cope with all the changes that are constantly occurring in his profession, and in this comparatively small matter there need be no dubiety as to the result, once he has made up his mind there exists room for improvement.

To say we ought to reduce the number of varieties is merely repeating what has been many times said already. It is, however, so important that this point cannot be passed without again drawing attention to it. Particularly as regards putting a limit to early sorts, and cultivating only those that succeed best in a given garden, it is important that a change should be made. The substitution of reliable late varieties for those affords at once the means of increasing the spring supply. And we cannot be too careful in the introduction of late sorts. Any variety, however handsome in appearance, the fruit that is subject to disease or that does not crop regularly should be passed over, and the number of trees of those that are dependable correspondingly increased.

No. 2694.—VOL. CII., OLD SERIES.

In small gardens this system of rigid selection should certainly be enforced, though a more elastic method may prevail where increased space permits the inclusion of a great number of sorts. But with a well selected stock of varieties it is neither impossible nor improbable that imperfect results may follow, and this because late varieties require special care in cultivation.

The easy method of being content with a full crop one year while the tree recuperates the next is a system unworthy of present-day achievements. Apart, therefore, from uncontrollable difficulties of weather, we ought to manage the trees in a manner calculated to secure an annual crop with unfailing regularity. For one thing, the peculiarities of each variety must be studied. Tower of Glamis, for instance, fruits more regularly and produces a crop of better quality when not too severely pruned. Alfriston, on the other hand, requires close pruning. But these are merely details that may be picked up by anyone who attends the trees. In addition, there are a few general points of management which must be carried out in order to succeed, and though they appear sufficiently simple once a grasp has been effected of the principles on which they rest, I am afraid they are too often overlooked altogether.

There is first of all the primary one of securing uninterrupted light to every leaf, as well as plenty of space for its development; and with that, every shoot and branch so adjusted as to secure an absolutely clear space free from the obtrusion of any other. Put in another way, the number of branches and shoots must be limited, not only to those it is possible to allow air and light to reach on every side, but to what the judgment and the experience of the cultivator finds does not strain the powers of the tree to preserve in fruitful health. This necessarily reduces the amount of foliage, but it is wise in addition to examine spurs and to thin them also, where necessary, to only the strongest, and these further limited to the needful number. By these means, as far as it lies within human intervention, we have a tree equipped and in a condition to respond to its natural proclivities to fruit bearing; and if fruit does not follow, apart from the disturbing element of weather, we must look for the reason either in the variety being naturally shy to fruit, when it must be displaced, or to the roots requiring attention, when they must be pruned, raised, or otherwise treated as may appear necessary. It is a fact patent to anyone in the habit of visiting gardens in different parts of the country, that Apple trees as a rule are much too closely, or thickly, furnished with branches, and also with spurs. Once the cultivator is convinced of this, he is fortunately not confined to one particular season of the year to initiate amendments. Spurs may be regulated at almost any season, and immediately growth is in progress in June branches and shoots may be excised without any risk of endangering the health of the tree.

So far we have only provided conditions the most proper to produce fine fruit, and plenty of it, though those who have not studied the question thoroughly may demur as to the matter of quantity. Now the equally important management of the crop while on the tree remains to be touched on. First of all I may say that varieties must be treated according to individual idiosyncracies, some requiring to be thinned more severely than others; that is to say, one sort fails to carry a crop so heavily as another, but that point I do not here insist on so much as the necessity of thinning the fruit of all late varieties to what many people might be constrained to designate a small crop, but which one's ripened judgment approves as amply sufficient for the tree to bring to maturity—not, be it understood, a few of the fruits, but the whole. Taking an average of years I have no doubt whatever that in bulk of fruit the severely thinned trees exceed those unthinned, while as to quality in any year the examples surpass the latter.

There are two outstanding reasons why late varieties should be lightly cropped. One, that the fruit is better grown, fully matured, and consequently keeps better and longer. The other, that the trees assume a habit of bearing a crop year after year, which in itself is infinitely more to be desired than a superabundant supply at irregular

intervals. There is no method of securing these two desirable results other than by severe thinning. But still that is not everything, for unless the fruit is allowed to remain long enough on the tree to become matured, the value of late Apples is greatly lessened. Last autumn, for instance, towards the end of October we experienced a serious gale of rain and wind which brought not a few late Apples to the ground. I rather regretted the loss of much of the fruit which was large and good in quality, so, as it was fully grown, I stored after drying all the late ones. These kept wonderfully well, but for some time much of it has shrivelled, just as late fruit does which has been stored too soon. That left ten days to three weeks longer on the trees has not, however, shrivelled at all, and in colouring the difference is markedly in favour of that which hung the longest.

I am sometimes met by what seems an unanswerable argument when advising Apple thinning—the time it swallows up. That I can assure everyone is a bugbear. A properly managed tree does not require so very much thinning, and it is marvellous how much can be done by nimble fingers and sharp eyes in a few hours. And ultimately the labour is well saved, when nothing but fruit of good quality remains to be gathered for storing. System in this as in other garden management, though apparently laborious, tends to an essential saving in work.—B.

Some of the Uses of Lime.

LIME in a garden soil favours the decomposition of the organic matter which has been added by the litter of stable manure, or by the refuse of crops dug into the earth. The action of lime on the organic matter is to produce carbonic acid; this chemical element combines with the mineral ingredients of the soil in such a way as to render the natural plant food easy of assimilation. Lime also plays an important part in changing the ammonia of the soil into nitric acid, or, in other words, placing at the disposal of the growing plants the nitrogen which has been previously stored up in a non-usable form.

There are certain garden plants belonging to the Leguminous family, such as Broad Beans, Peas, Scarlet Runners, and French Beans, which draw their nitrogenous food very largely from the atmosphere. But these plants are unable to make a satisfactory growth if the soil is overcharged with acidity. Hence we sometimes find in very old kitchen garden soils that Beans and Peas will make plenty of haulm but produce few pods and little corn. It seems that the minute organisms which dwell in the nodules or small tubercles that are formed on the roots of legumes cannot thrive if the soil is charged with humic acid. By the application of lime this acid is neutralised, and the Beans and Peas will grow more readily and yield more corn, not only because soluble nitrogen has been assimilated, but from the fact that the lime acts upon the potash compounds in the soil in such a way that they are set free for the use of the legumes and they become carriers of nitric acid.

Of course excessive amounts of lime might prove injurious to some garden plants, but this can easily be guarded against, and the amount required by different soils be determined by a few trials. Old lime and mortar rubbish are especially suitable for garden purposes, as this material greatly facilitates the formation of nitrates in the soil, and helps in its mechanical disintegration—a great boon in heavy land.

Thus lime applied to stiff clays causes them to become more friable, more permeable to the air, easier of working, and better capable of supplying water to the growing plants as needed. Sandy soils, on the other hand, are rendered by it more compact and more retentive of water and manurial substances. On very dry sandy soils smaller applications of lime must be made than upon moist soils, and the use of large quantities of lime upon such soils in single applications is not advisable. Also we have to remember that lime, without manure, will soon make a garden poor, the reason for which is not far to seek if these facts are considered.—J. J. WILLIS, *Harpenden*.

**Odontoglossum crispum The Earl.**

ON page 367 of our issue of May 3rd we gave a representation of *Odontoglossum crispum* Victoria Regina, from Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs, and we now present O. c. The Earl (fig. 110) from the same source. This variety was shown at the Drill Hall on April 24th, and was recommended for a first-class certificate by the Orchid Committee of the Royal Horticultural Society. It is one of the handsomest of the showy section of crispums that has been exhibited, and was greatly admired by everyone present at the exhibition on the date named. The ground colour is pure white, this being almost obscured on the sepals by brown; the petals have large blotches of similar colour.

Odontoglossum crispum aureum rosefieldiense.

No two illustrations than that of O. crispum aureum rosefieldiense (fig. 111), and O. c. The Earl (fig. 110), could better illustrate the varying characters of form and colour in this popular Orchid. Mr. de Barri Crawshay, Rosefield, Sevenoaks, is to be congratulated once again on having brought forward one of the most refined varieties of O. crispum that has ever been shown. The Orchid Committee at the Drill Hall on May 8th recommended a first-class certificate, and the honour has rarely been better deserved. In shape the flower is practically perfect, as also is it in substance. It is rather small, but the excellent culture to which the Rosefield Orchids are subjected will probably make a difference in this direction in the course of a year or two. The prevailing colour is soft canary yellow, there only being a little white at the base of the petals.

Vanda teres.

This Vanda is very beautiful when grown under proper conditions, but old leggy plants 6 feet or 8 feet high, with pale washed-out looking flowers, are just the reverse. In most collections where it is really well done a house or compartment is devoted to it, or at least any other species therein grown are made to conform to its treatment.

FIG. 110.—ODONTOGLOSSUM CRISPUM THE EARL.

The plants are frequently cut down and re-rooted, so that instead of the upper tier of roots rambling about in an atmosphere more or less unsuitable to them, they have the choice of compost or air.

But there are, of course, many growers with a representative collection who do not wish to grow a large number of any individual

kind, and the cutting down system is not so suitable for them; but a pole or trellised block placed in the centre of a pot or basket and covered with moss strikes a happy medium between the two systems, and is often successful. The roots have the chance of entering the moss and thus strengthening the growth. Always choose the warmest house at command for it, and there is perhaps no other Vanda that requires so much sun.

Cattleya Lawrenceana.

There are few more showy or beautiful Cattleyas than this, its fine rose and crimson-purple blossoms, so freely produced, making the plant a favourite everywhere. Fortunately it is reasonable in price; it is also of simple culture, provided the atmospheric conditions of the house are right. It likes far more sunlight than the majority of Cattleyas, and also if convenient a little more heat, though if this is not easily arranged for it gets along fairly well with other kinds. No one need fear to buy it, as it is bound to please them when it flowers.

Feeding Orchids.

Probably there are many cases where a little manuring of Orchids, even of an epiphytal character may do good, but there are many others where it certainly does harm eventually, though for a time the plants appear to be luxuriating in fine foliage and handsome

FIG. 111.—ODONTOGLOSSUM CRISPUM AUREUM ROSEFIELDIENSE.

flowers. Such a case came under my notice recently, when some fine old clumps of *Dendrobium nobile* were being pulled apart for propagating purposes. Although exceptionally good growth had been made, the roots had not that hard appearance which denotes health and ability to stand a check from disturbance, and the plants are now breaking very weakly.

Instead of giving new material these plants had been treated to occasional doses of weak soot and guano water, and it has not served its purpose. Had the plants been repotted a couple of years ago all would now have been well, and much of the new compost would have adhered to the roots when these were moved, serving to re-establish them in the new quarters. As it is the old peat was tainted and black looking, and it would not have been good policy to have placed it in the new pots.

Feeding in my opinion, and according to my experience, must never be made to take the place of new material. If it does, however good the result may be for a time, the plants will be worse for it when repotting again becomes necessary. There are many instances where feeding judiciously carried out is productive of much good. Some of the very finest *Miltonia vexillaria* I have ever seen were always given a weak dose of liquid made from soot and cow manure when the spikes were expected, unless freshly potted, and here the results fully justified the practice.

Had it been applied every season instead of giving new compost, there would have been a different tale to tell no doubt. So far I have not mentioned terrestrial species such as *Cypripedium* and others, or epiphytes treated as terrestrial like *Thunias* and some *Calanthes*. Here there is no doubt that a little feeding has in many cases helped, by causing the plants to produce flowers of higher quality without endangering the roots. But vigorous leafage is not always a sign of increased health.—H. R. R.

A Chat About Fern Raising.

THE propagation of Ferns by means of seeds or spores has, in great commercial establishments, now reached the dimensions of an important industry. Millions are raised and sold annually in tiny pots, in addition to the vast numbers which are potted and disposed of in those popular-sized pots—viz., 5 and 6-inch. The trade has, indeed, been entirely revolutionised since the old days, when the secret of Fern raising was known only to the few, and when the majority depended upon root division as a means of increasing their stocks.

This continual process of raising seedlings has also had the effect of bringing hosts of new varieties to light, for when several species and varieties are grown in the same house cross-fertilisation is frequently the result, and even when seed is saved from plants growing in a house devoted entirely to one variety, we invariably find a few of the seedlings distinct from the type, though not always superior. Varied, novel, and beautiful as are the many species and varieties of Ferns now grown, there will, I think, in the future be still more diversity among them—a diversity which will be bewitching as well as interesting. There seems, in fact, to be no limit in regard to the good things to be expected in the days to come, and those who practise systematic cross-fertilisation will perhaps be able to give us a new race, with bold broad fronds, as well as others with serrulated and crested ones of an entirely new type. That grand variety *Pteris Drinkwateri*, which is a marked improvement on *P. major*, seems to have taken us a long way upon the road by which we may hope to secure varieties having fronds as bold as *Kentias*, and in *Osmunda japonica corymbifera* we have a splendid Fern for decorative purposes, as the formation of the fronds is distinct and striking, and their rosy pink colour quite novel.

In private establishments small Ferns are in great demand, for the modern decorator finds innumerable ways in which to employ them to advantage, but I fear that in only very few instances is the supply equal to the demand, for it is an undoubted fact that private gardeners—as a rule—have not kept pace with the times in regard to Fern raising, as they usually rely upon chance seedlings which come up in the fernery or on the walls of other houses, for increasing their stock. This is, however, not a matter for surprise, as private gardeners labour under difficulties which do not exist in large commercial establishments, where specialists are engaged for such work, while the gardener with his multitudinous duties seldom gets the opportunity to study and work out the really simple details which are essential to success. For these reasons I trust a few remarks on the subject will be helpful to any who require such information.

The most important detail in connection with the matter is, undoubtedly, to secure fronds loaded with spores just in the "nick" of time. Many have failed in raising Ferns from promising looking fronds solely because they were gathered too late; the spores had dropped, only the cases or sori remained. The selected fronds should be examined frequently, and when the cases are of a rich brown colour the fronds should be cut, enclosed in paper bags, and hung in a dry room or a sunny position under glass. If the fronds are not gathered till the sori is dark in colour—almost black—the work has been too long delayed and the spores have vanished. A little close observation and a few trials should, however, soon enable anyone to determine the exact stage at which to gather the fronds. After they have been hung for a week the spores are ready for sowing. Some will have dropped into the bag, but in order to secure as many as possible I lay the fronds on a stiff sheet of white paper, and scrape off the brown substance with a knife.

Prepare a compost formed of equal parts of well decayed turfy loam and peat, add to it a sixth of sharp sand, and thoroughly burn the whole over a slow fire till it is quite black. This burning of the soil prevents the growth of moss, which is so troublesome in Fern raising when unburned soil is used. Sift the compost through a quarter-inch riddle, drain a number of 6-inch pots to a depth of 3 inches with ashes or finely broken potsherds, cover this with some of the soil siftings, and finish off with fine soil pressed moderately firm; make it level on the surface, which should be half an inch from the top of the pot. Water thoroughly through a fine rose, then scatter the spores thinly upon the surface; as these are very minute a very small pinch will suffice for each pot; lay this on a small sheet of white paper, and scatter it evenly over the soil.

After sowing place the pots in saucers of water, cover them with a sheet of glass, and stand them in a close frame in a propagating house. The saucers should be kept constantly filled with water, to avoid overhead watering, and until the spores germinate keep the frame constantly shaded. After that stage has been reached, remove the shading early in the evening and replace it before the sun shines upon the frame. As growth progresses admit a little air, and as soon

as the seedlings are large enough to handle prick them out in shallow boxes filled with burnt soil. When doing this do not attempt to single them out, but lift little tufts with the point of a penknife and set them an inch apart. Return the boxes to a propagating frame, water through a fine rose, sprinkle lightly each day, and shade as required. When the "youngsters" are large enough to handle conveniently divide the clumps, and again prick out in boxes. Two or three may be left in a clump, to form bushy little pot plants, or they may be pricked out singly. The next shift should be into very small pots; shallow Fern pots are especially made for the purpose, as these are of convenient size for dropping into china and other pretty ornaments, in which "baby" Ferns are now so often placed.

Those who require plants somewhat larger can transfer them from these small pots into 3-inch ones, in which size they are extremely useful to gardeners for decorative purposes. The pretty Edwardian ware, which is made in various sizes and designs, supplies some of the most suitable receptacles of which I know for accommodating Ferns. *Adiantum*, *Pteris*, *Phlebodium*, *Cyrtomium*, *Lygodium*, are all popular Ferns, which may be easily raised from spores.

The *Asplenium*s are quite as easily increased by inserting the small bulbils, which form on the upper parts of the fronds, in burnt soil. They grow very slowly, but with proper treatment 95 per cent. of those inserted will grow. The best time for sowing is from January to the end of June, as those sown at the latter time get well established before the dark days of winter come. Success may, however, be secured by sowing at any season of the year, though in autumn the progress made is very slow. Throughout the summer months Fern houses ought to be kept close, very moist, and the young plants sprinkled lightly once or twice daily during bright weather. Shade should, of course, also be afforded. During autumn and winter do not sprinkle, but keep the atmosphere moist by repeated dampings; avoid doing this late in the day, especially in the management of plants in old houses, or moisture will settle upon the fronds at night and bring brown spots and stripes in them. A temperature of from 60° to 65° during winter is a suitable one for young seedlings.

At all seasons of the year when a stock of young plants is ready for use they ought to be removed to a cooler structure for a couple of weeks to harden the fronds; they will then last in good condition for a long time.—H. D.

Ribes sanguineum.

THE flowering Currant is an old and universal favourite in most parts of the country, and deservedly so, as it is easily accommodated, and has a good effect when in flower. The typical plant is a native of North America, and has pendulous racemes of flowers of a pale red colour, which are not nearly so effective as some of the forms which have been raised from it. These vary in colour from nearly pure white to a deep crimson, and form some of the most attractive of outdoor plants when in flower. A few of the best are *albidum*, which has long racemes of nearly white flowers tinged with pale rose, which, however, does not detract from its beauty; *carneum*, one of the best, with long racemes of a deep flesh colour; *Davidiana*, a form of continental origin, which has flowers of a deep rosy pink, and is very free flowering; *atrosanguineum*, with flowers of a deep purplish crimson hue, and which is the best to have where only one is grown; and *atrorubens*, in which the racemes are shorter, and the plant rather dwarfer and more spreading; the colour is deep bright crimson.

There are several other varieties, but those named above are the best for general purposes, the others not being very distinct, with the exception of *flore-pleno*, which has double flowers of a deep red colour. All these are easily raised from cuttings of the young wood taken in winter, and put in the open ground; *albidum* and the double one should be kept in stock, as they are both apt to die off suddenly from some cause or other, the plants often seeming in good health in the autumn, but failing to start the following spring. Cuttings, however, are easily rooted, so that it is not difficult to have sufficient plants to make good any losses.

Generally speaking no pruning is required, but occasionally a plant becomes ragged or in bad health, and then a cutting back after flowering induces young and vigorous growth. Thinning of the branches is required at times, where a plant has become too thick, and the shoots crowded together. None of these plants seem to be particular as to soil, but they all repay any attention bestowed upon them in the way of feeding and watering.—C.

Rose Show Fixtures in 1900.

- June 13th (Wednesday).—York.†
 „ 27th (Wednesday).—Salisbury (N.R.S.), Richmond (Surrey),* and Southampton.*
 „ 28th (Thursday).—Canterbury and Colchester.
 „ 30th (Saturday).—Windsor.

* Shows lasting two days. † Shows lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear in an early issue.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Seasonable Topics.

THE few days of sunshine recently have caused the Rose trees to push their growth buds most rapidly, but with nightly frosts of more or less severity one is anxious about the tender shoots becoming crippled in their infancy. For this reason it is unwise to be in too great a hurry to remove any; rather leave all for a time, so that we may make a good selection from the fittest to provide the blooms. The shoots do not draw much from the tree until they have attained to a considerable length, so that no harm in that way is done by leaving them at present.

Timely attention should be given to insect pests. The maggots and aphides come in most seasons. In the former case hand picking is the only remedy. A curl in the leaf, or the point of a young shoot with its tiny leaves clinging together as it were, is a certain indication of its presence. These leaves must be carefully unfolded, and the enemy captured. In the case of green fly, syringing is the best remedy. We like the insecticide known as "Abol," a preparation recommended for Hops. This is easily applied, and not the least of its merits is that it readily mixes with water, so that there is no trouble in boiling. What is most important is that aphides should not be allowed to get the upper hand. These tiny insects become so numerous as to suck all the virtue from the growth, leaving none to perfect the blossoms.

The Value of Soil Loosening.

Stirring the soil about the plants is a constant item of culture. This keeps down weeds, makes the beds tidy, besides letting air into the earth. The strawy portion of manure put on for winter protection is cleared; the other becomes mixed with the earth by hoeing. In the case of newly planted Roses watering is thus early necessary, at least on light soil, and we also water established trees with liquid manure. Roses out of doors cannot be overgrown. They seem to take any amount of feeding and moisture. The blooms of some sorts come quartered and ugly in shape, perhaps, when the growth is vigorous; but we would rather counteract this habit in allowing an abundance of flowering shoots on a tree than by starving the same at the roots.

That very strong growing variety *Her Majesty* is an instance of this. It is apt to produce coarse blooms. It has also a trait in producing few shoots to a plant. We were advised to prune early—

in December—and this practice certainly has made the plant bushier in growth. That is to say, the lower as well as the upper "eyes" are starting into life.

A Trio of Beauties.

What a splendid Rose for pot culture *La France* is. Seldom do we get it to come into its best form in the open. The blooms are so easily spoiled by moisture, but under glass every bud opens perfectly, and the shape as well as colour are so taking. It grows equally well budded or grafted on a stock as on its own roots, and roots easily. The half-ripened stems that have produced blooms give plenty of material at this time to propagate. These should be cut into lengths of about 6 inches, placed round the edge of pots filled with light sandy earth, and stood in a closed frame within a cool greenhouse. Climbing *Niphetos* is a Rose which should not be neglected as a climber under glass. It grows freely and is a profuse bloomer. We recently noted a fine plant of Climbing *Devoniensis* in a conservatory bearing hundreds of flowers. This old variety is somewhat left behind by newer rivals; few, however, can compete with it when seen covering a space of at least 100 square feet. Loose training and little pruning appear to suit it, as long branches were hanging in full flower some distance from the roof. The tree was growing in a cosy end of a large structure where it is not subject to cold draughts, which are so detrimental to Roses under glass.—H. S.

Thinning Shoots.

Now that shoots are pushing freely on bushes, standards, and climbers, there will inevitably be growths that are of a superfluous character which require to be rubbed out. This may be done with much benefit to the plants, as the removal of those which are useless tends to improve the shape of the bush or tree, and the plant's vigour is directed to the development of growing wood or flowering shoot. An important advantage also is the freer admission of light and air, of which Roses appreciate an abundance. These conditions enable the lesser shoots and all the leaves to develop strongly and build up tissue which proves less liable to attacks from insect pests. In regard, however, to disbudding or the removal of weak shoots, it is apparent that no set rule can be laid down as to the course to pursue. The main principle may be grasped, which is that weak shoots must not be allowed to crowd the best and most promising, and this may usually be effected by the entire removal of shoots here and there.

The Removal of Suckers.

Suckers must be regarded as superfluous growths springing up out of place and abstracting from the soil food and moisture, and also tending to obstruct the light. If removed early the process is far easier than when they are allowed to remain gathering strength. The suckers, too, may prove detrimental in weakening the vigour of the roots. This will undoubtedly be the case with suckers from strong-rooting stocks upon which the Roses are worked, as, for instance, *Briars*. These are readily recognised, and should be removed cleanly, if possible, from the roots close to their origin. Own-root Roses may, and do, develop suckers which are found some distance from the plants in many cases. Allowing them to remain will eventually prove a source of annoyance and detract from the order and neatness of a small Rose bed or a large Rose garden. The tendency to produce suckers must be reduced as far as possible by their careful removal.

Hoeing and Feeding.

All beds, borders, and plantations of Roses may have the Dutch hoe run over them frequently now in order to cut down seedling and other weeds, and as a means of cultivating the soil, favouring clean and healthy growth, as well as promoting vigour. After these important and highly beneficial operations the next step is to apply a mulching. This may consist of horse droppings, half decomposed, and saturated with liquid manure. Spread it over the roots about a inch thick when the buds have formed and are swelling. The fertilising matter contained in the manure will, during rain, be gradually washed down to the roots, imparting vigour to the growth and improving the blooms in size and depth of colour. In the absence of rain artificial waterings and the application of liquid manure act equally well, if not better, in conveying due supplies of stimulants to the roots.

Soot is a capital manure for Roses, and is best applied in a liquid form. Mix a peck of soot into a paste with a little water, and then place in a bag, which tie up and sink in a tub of water holding 25 to 30 gallons. After soaking well for a few days throw in a shovelful of lime, mix, and let it stand until the liquid, instead of having a thick inky appearance, is clarified like wine. Apply this to the Roses when the soil is moist. It will add a richer and deeper tint of green to the foliage, and assist in making the leaves proof against the numerous insects which are ready to attack, especially when the soil becomes exhausted of moisture. The flowers in consequence have more substance in the petals, as well as richer and more velvety hues.

Generous living and uniform moisture will do more in maintaining the plants clean and free from insects than anything else.

In good rich soil, which is kept moist by a light mulching of manure, recently planted Roses ought not to be stimulated too much the first season with strong manures. Growth of a medium character has a better chance of becoming well and thoroughly ripened than abnormally strong shoots which might be produced, hence the latter should not be encouraged on dwarfs and standards, but may be countenanced on wall Roses, which depend largely on strong shoots for furnishing the space.—SWEET BRIER.

Pot Roses.

Roses of the Hybrid Perpetual and Tea section are very useful for growing in pots to produce flowers early in the season under glass. The plants employed for this purpose, however, require to be specially prepared during the previous summer and autumn. The present time is very suitable to obtain well established healthy plants in 5-inch or even 7-inch pots, and grow them under favourable conditions in 8 or 9-inch pots for early blooming. Good specimens may be secured from any of the leading Rose nurserymen, the plants being worked on the Manetti stock. If well rooted plants are obtained they may have a shift at once into a larger pot. The pots must be quite clean inside, and be carefully drained with a small quantity of potsherds arranged round a large central crock over the hole in the bottom. On this drainage place a layer of clean fibre—that is, fibre with all the loose soil shaken out to prevent the soil choking the drainage.

Composts and Potting.

Good, rich, substantial compost is important, and if the top spit can be obtained from a clay soil pasture, stacking it grass side downwards for a period of three months, it should be in prime condition for the potting material. Chop it down into small pieces, adding about a sixth part of leaf soil and a fourth part of manure all thoroughly intermixed, and to each barrowload an 8-inch pot of crushed or dissolved bone manure, and a liberal admixture of sand will much improve it. The leaf soil should be of a sweet character, and the manure well decomposed.

The plant must be moist at the time of potting, so that it is not necessary to water the soil immediately after. On turning the plants out of pots remove the loose soil, which may come away easily from the ball, also picking out the crocks. Place the ball in the pot so that the surface will be just below the rim when the soil is filled in and a little placed on the top. As the soil is introduced make it firm. The new compost must be as firm as the old ball. With the compost moist as well as the plants no water should be necessary for a day or two; instead of applying it dew the plants with a syringe. Keep them on a cool base in a frame or in an airy cool greenhouse, the Hybrid Perpetuals being placed outdoors in June, plunging the pot in ashes to the rim. Attend strictly to the supply of water, never allowing the soil to become dust dry.

Destroying Mildew.

If mildew should attack any of the young shoots soapy water mixed with tobacco liquid will destroy it, also green fly. The pest known as orange fungus is a troublesome foe. As much of the diseased parts as possible should be cut out, and then treat the remainder to a dusting of flowers of sulphur, which also destroys mildew.

Housing.

About the end of September if the season should be wet remove the plants into a cool, airy house, but where this is not practicable an open shed is quite sufficient protection. Plants intended for very early forcing may be pruned as soon as the leaves fall, doing this when the soil is comparatively dry. These may be introduced into a structure kept steadily at a temperature of 45°, fairly close to the glass, and when leaves have formed increase to 55°. Early blooms are never so good as those developed under the influence of longer days. Disbud or thin out crowded growths. When flower buds have been formed supplies of weak liquid manure may be given. That made from cow manure and allowed to become clear is enriching. Slight applications of guano spread on the surface of the soil and washed in also promote healthy growth, but care must be taken not to apply it of more than ordinary strength. Weak and often is a safe rule with all manurial applications, given in the form of liquid or as dustings of artificial manure.

Good Varieties.

Some of the best Tea Roses for pot culture consist of Belle Lyonaisse, Cheshunt Hybrid, Gloire de Dijon, Madame Falcot, Safrano, and Niphetos. Among the Hybrid Perpetuals there are

numbers of varieties suitable. A few desirable are A. Colomb, Bessie Johnson, Duke of Edinburgh, Général Jacqueminot, John Hopper, Jules Margottin, Madame Victor Verdier, and Star of Waltham.—H. T.

Rose Pests.

THE growth of Roses under glass is now free and vigorous, and well-established plants will be flowering abundantly, especially the climbing varieties planted out in conveniently light positions. Considerable trouble has to be taken to maintain the growth clean and free from aphid, red spider, and mildew. Aphid or green fly is sure to attack the points of the shoots, and if the pests are allowed to remain a check may be given the plants, for the insects will increase rapidly, invading the whole tree, and cause endless trouble in destroying them, besides covering the foliage with sticky secretions. Syringing the growth frequently is a good method of preventing them making their first attacks, if not of destroying them. If, however, instead of syringing with clear water a rather weak insecticide is employed, the increase of green fly must be considerably checked. If measures are taken sufficiently early to render it difficult for insects to establish themselves, there will be less trouble afterwards. The aphid feeds on the young growth, sucking out the sap.

A softsoap and sulphur emulsion, with or without petroleum added, forms an excellent solution. The way to make the solution is to boil 1 lb. of soap to a gallon of water, adding half a pint of petroleum and 4 ozs. of flowers of sulphur, first mixing the latter into a paste. Thoroughly stir and boil again. This may be placed in a bottle when cold, and half a pint of it added to 2 gallons of water at a temperature of 70°. Constantly stir the mixture when using, so as to prevent the oil settling on the top.

The above insecticide will prove inimical to mildew on Rose growths, but it may be necessary to add a little more sulphur, in order that when the solution is syringed upon the leaves a deposit is left which will ultimately destroy the fungus. Spraying on the solution is probably better than syringing, as it can be done much finer, and is more economical and effective.

Red spider is another insect which attacks Roses under glass, but it should, and may be, of rare occurrence, as it only attacks trees which are growing in a dry atmosphere, or established in a poor border which has been allowed to become deficient in moisture. If the atmosphere of the structure is kept moist by damping the floors, walls, and borders, the roots at the same time having substantial moist soil, a slight attack of red spider may soon be cured. If sulphur is mixed into a paste and spread on the hot-water pipes, which should not be kept too hot, fumes will be given off which destroy red spider. The growths ought also to be syringed with the sulphur and soap remedy.

Green fly and mildew also attack Roses outdoors. If any wall Roses are growing in a dry position, mildew will almost certainly attack them. Bush plants and standards are subject to it in poor exhausted soil. One of the first means to be adopted in fortifying Roses against mildew is to moisten and enrich the soil. Many specimens of wall and trellis Roses are undoubtedly ill treated in the supply of moisture for the roots, hence their unsatisfactory condition in flowering, and subsequent growth made for future blooming. Well moisten the ground with a copious supply of clear water, loosening the surface as far as the roots are likely to extend, so that the water may pass direct to them; follow this by a free supply of liquid stimulant, and a top-dressing of manure to retain the moisture thus applied. Syringe the stems and growths freely and vigorously morning and afternoon, the insecticide being applied in the evening, both for outside and inside plants.

Another insect which attacks indifferently cultivated and neglected specimens outdoors is a white or yellowish fly, rather larger than the green fly. This does much damage to the foliage, chiefly in eating the under or lower cuticle of the leaves, giving them an extremely unhealthy and spotted appearance. More liberal watering, syringing, and the application of an insecticide will assist in exterminating it, but to absolutely prevent the recurrence of this insect another season there must be increased attention given to the supply of soil moisture.

The Rose maggot is a grub of an injurious character, often destroying the tips or points of valuable shoots, as it feeds on the youngest and tenderest leaves, shoots, and flower buds. No insecticide is a remedy for this grub. It should be sought for early. The best indication of its presence is the rolled up leaves. Press these between the finger and thumb and the grub will be killed. If attention is given early, so as to find the first marauders, further mischief may possibly be averted. When the maggots emerge from their hiding places, and are not feeding on growth, they can often be seen suspended by silken threads. By persistently hunting down the maggots they will gradually lessen in number and finally disappear in succeeding seasons. Thrips only attack Roses in dry seasons. Brown scale is a troublesome enemy on the young growth. It is chiefly destroyed in winter while growth is dormant.—ROSARIAN.

NOTES & NOTICES

Recent Weather in London.—The weather in London has, of late, been most unpleasant. There has not been any appreciable amount of rain since last Saturday, but high north-easterly winds have prevailed with very low night temperatures. These cannot be other than prejudicial to the present wealth of blossom, and everyone is looking forward to a return of more genial conditions. The sun has shone brightly on each day. Wednesday opened clear and cold.

Large Seakale.—I have forwarded to you examples of remarkably fine Seakale, kindly sent by Mr. H. T. Martin, gardener to Lord Leigh, Stoneleigh Abbey, Kenilworth, to the recently held fortnightly meeting of the Birmingham Gardeners' Association. They form a portion of the thirteen heads weighing collectively 11 lbs. In his note Mr. Martin stated that it is the produce from one year old sets, and out from the open ground, unforced. [The produce was admirable in all respects, and worthy of the reputation Mr. Martin has already made for himself as a vegetable grower.]

Royal Horticultural Society.—The thirteenth great flower show of this society, held annually in the Inner Temple Gardens (Thames Embankment), will open on Wednesday next at 12.30. Judging from the large number of entries received, the show promises to be quite up to its usual standard of excellence. The following well-known amateurs are among the names of intending exhibitors:—Duke of Northumberland, Nepenthes; Lord Gerrard, Carnations; Lord Wantage, K.C.B., fruit and vegetables; Sir Trevor Lawrence, Bart., Orchids; Sir J. Pigott, Bart., Crotons and Palms; Sir J. Pease, Bart., fruit and vegetables; Sir F. Wigan, Bart., Orchids; Alex. Henderson, Esq., M.P., fruit and vegetables; Henry Little, Esq., Orchids; R. I. Measures, Esq., insectivorous plants; Ludwig Mond, Esq., Orchids; Leopold de Rothschild, Esq., Water Lilies in tubs and fruit trees in pots.

The Lincolnshire Daffodil Crop.—It is said that Daffodil growers in Lincolnshire have had a disappointing harvest in consequence of the low prices obtained for their flowers. This has been in a large measure due to the early varieties being somewhat later in flowering than usual, owing to the cold weather experienced early in the spring, and the consequent flowering of both early and late varieties within a brief period. The prices obtained for a portion of the Lincolnshire flowers were, it is stated, not more than sufficient to pay the cost of gathering and conveyance to market.

Richmond's New Laboratory.—Some details are now forthcoming with reference to the new physical laboratory to be erected, under Government control, in the Old Deer Park, Richmond. It will consist of two buildings, which will be placed, not adjoining the present observatory in the centre of the park, but on a strip of ground enclosed for the purpose alongside the boundary between the park and Kew Gardens. This site, about 15 acres in extent, commences immediately at the rear of the archery ground in the Kew Road, and runs westward towards the Thames. At the end nearest the road and to the Kew Gardens Pagoda—which will itself be utilised for purposes of the laboratory—will be erected, says the "Morning Post," a somewhat extensive one-storey building, devoted to the testing of commercial samples. At the far end of the site and adjoining one corner of the Queen's Cottage grounds, there will be a smaller two-storey building, which will be used for the purpose of carrying out a variety of magnetic and other physical experiments, success in which imperatively demands seclusion and freedom from disturbance, either physical or electrical. A very small number of persons will be employed at either of these buildings; the work will all be carried on with perfect quietness and within doors, and there will be no smoking chimneys or other disfiguring appendages. The motive power required in the testing house will be supplied in the form of electricity and by cable from outside the park. There will, in fact, be nothing of a character to disturb the bird life or other attractive features of the adjoining gardens, and in their architectural features the buildings, designs for which will be prepared by the Office of Works, will be as unobtrusive as possible.

Death of Mr. Alfred Salter.—We learn with regret of the death on May 5th of Mr. Alfred Salter at Kensington. The deceased was the son of the late Mr. James Salter, a name held in high esteem by those who are conversant with the services he rendered in the cause of the Chrysanthemum. Mr. Salter was seventy-five years of age.

Trees in Dublin.—During the past week the trees which are on some of the principal thoroughfares were given new compost, an operation which is becoming of yearly importance owing to the open grating which covers the roots and favours an accumulation of rubbish. It is strange that some method cannot be devised to obviate this difficulty, as there is a certain amount of deleterious matter likely to enter, which acts as a check on the growth of the trees.

Sweet Peas.—We have received from Mr. W. Hunt, Fern Hill, a box of Sweet Peas, as illustrating their value at this period of the year. The collection comprised sixteen distinct varieties, and we must congratulate our correspondent on their general excellence. The flowers were for this early season of good size and substance, and the colours were splendidly developed; while the growth was exceptionally robust. The varieties included Countess of Powis, Salopian, Navy Blue, Blanche Burpee, Lady Nina Balfour, Waverley, Boreatton, Mrs. Eckford, Monarch, Splendour, Captain of the Blues, Purple Prince, Stanley, and Emily Eckford. Such bouquets as these are more than welcomed in smoky London at this season of the year, when sweetly perfumed flowers are all too scarce.

Stealing Flowers at Shows.—The Temple Show is nearing us once more, and it behoves us all to aid each other in preventing anyone appropriating even a bloom. It is not an unheard-of thing at shows all the country over, and it has been very forcibly brought to my notice once more by someone having taken a bloom off my *Odontoglossum crispum* (*Imperatrix roseum*), at the Drill Hall on the 24th ult. I have no doubt this magnificent variety was chosen for definite reasons. Of course I blame no one connected with the Royal Horticultural Society, as it would not be done were any official near, and we cannot expect our plants to be watched all the time. It is an extremely annoying thing, and the surest means of preventing it is to ventilate the subject in the Press. The old offenders may not care to repeat it; another time they might be detected. —DE BARRI CRAWSHAY, *Rosefields, Sevenoaks.*

Cheap Nitrogen.—There is little doubt at the present time but what one of the cheapest ways to supply nitrogen to our crops is through the manure of well fed animals. Nitrogenous feeding stuffs have, says a writer in an American contemporary, been plainly shown, both by experiments and by practical feeders, to have a marked effect in increasing the amount of milk, and at the same time their use has proved economical. Experiments made at the New Jersey station, which are being followed out for a series of years, show that the manure from cows having a nitrogenous ration produces larger crops than that from cows having a carbonaceous ration; thus the double value of feeds rich in nitrogen is clearly shown. Where a profitable class of live stock is kept and nitrogenous feeds are freely used, the farmer may depend largely upon his manure supply as a source of nitrogen, and let the purchased plant food be mainly phosphoric acid and potash, which will cost only one-third to one-half as much per lb. as nitrogen.

The Black Currant Mite.—Hydrocyanic acid gas has for some time been used successfully in the United States against scale and other insects, and recently the authorities of the South-Eastern College at Wye have experimented with the gas on Currant plants infested by the mite. From trials made on young plants before planting very encouraging results have been obtained. In December and January there are no eggs in the buds, and if the plants are freed then they may be regarded as safe. This was shown to be the case, and now it is recommended that systematic trials should be carried out in orchards where the pest has become established. Where it is desired to do it on a business-like scale, it is suggested that sheets of oiled calico 25 yards long and 8 feet wide should be set up over the bushes, and that three jam pots placed equidistantly apart, each containing 1 oz. of cyanide of potassium, 2 ozs. of sulphuric acid, and 2 ozs. of water, should be placed under the sheeting. The water and acid should first be placed in the pots, then through an opening the cyanide, wrapped in thin blotting paper, should be dropped into the pots, the hand being quickly withdrawn and the hole closed, keeping the bushes under fumigation for forty minutes. This is necessary because of the singularly poisonous fumes which are given off, and which are exceedingly dangerous.

Horticultural Congress at the French Exhibition.—This reunion of horticulturists, which has already been announced, we would now remind our readers, will commence next week upon May 25th. The duration of the congress will be three days, and it is to be hoped that the character of the gathering will be truly international, despite the reports of the backwardness of the exhibition. Those English horticulturists who cannot attend thus early in the season should recollect that the Congress on Arboriculture and Pomology takes place at the Exhibition in the second week of next September.

St. Ives Horticultural Society.—The schedule of the twenty-fifth annual exhibition of this society has reached us from the hon. secretaries, Messrs. R. M. Copley and R. Warner, St. Ives, Hunts. The date of the show, which will be held in grounds adjoining Somersham Road, is fixed for Thursday, July 26th, 1900. The majority of the classes are open only to cottagers and amateurs, but there are several which should draw those who do not come within either of these sections. There are upwards of eleven dozen classes, and broadly speaking every phase of seasonable gardening is covered. Schedules and any further necessary information will be provided by either of the secretaries named above.

Wolverhampton Chrysanthemum Society.—At a general meeting of the committee of the above society, it has been decided to abandon the usual annual show for this year. Owing to the heavy calls upon the subscribers, it is feared that it would not receive the support which has been accorded to it in the past. It may be mentioned that another reason for the decision of the committee is the poor support which the society received last year; this the committee do not think was from any diminution of interest, but was no doubt owing to the general depression consequent upon the commencement of what is proving to be a protracted and costly war. It is the intention of the committee, however, to hold the show next year, when it is hoped prospects will be brighter in every way, and that the public will combine to make the show a success.—J. WHEELER, *Hon. Secretary*.

Beckenham Horticultural Society.—Mr. James Hudson, V.M.H., read a paper before the members of the above society, on May 11th, at the Beckenham Public Hall, on "The Cultivation of Fruit Trees in Pots." The subject was dealt with in a masterly manner. Numerous instances were given of rotations of three distinct kinds of plants being grown in same house in one season; for instance, Peaches, Nectarines, and Plums, removed the third week in June, made way for a crop of Melons, to be followed by Salvias, and ready again for fruit trees. Nine or ten-inch pots were considered ample, and annual potting was recommended. The temperatures were very important factors, too high a night heat conducing to wood growth. Peaches, Nectarines, Plums, Cherries, Figs, Apples, Pears, and Apricots were all dealt with, and much useful information gathered by those present. Messrs. Taylor, Burge, Crosswell, Webster, Price, Russ, and others joined in the discussion, and unanimously accorded a hearty vote of thanks.—M. W.

Agricultural Societies.—An important meeting was recently held relative to an organisation to be formed to manage the New Ross Agricultural Society. There was a representative gathering of all classes, especially of men whose sphere of activity lies in land management. The present move was convened by circular, and it was held in the Court House of New Ross, under the presidency of Captain B. Hamilton. After the secretary, Mr. Tyndall, had read the minutes of the previous meeting the chairman referred to the lines on which they intended to work the society; he did not, he said, mean to alter the constitution of it, but to widen the field of operation; he referred to a feeling which had gained a certain amount of credence, that they intended to have something to do with the co-operative movement, and he desired to give that rumour an absolute denial. The real object was to perfect the two following ideas:—1, The development of agriculture, and 2, the breeding of stock, and he hoped that the farmers from all quarters would lend a helping hand. Mr. Barron wished to know if they would be entitled to receive a grant from the new Agricultural Board. The secretary in reply thought they would get a grant. Mr. Thorpe proposed that the old committee be retained, and to add the requisite number of the new society, which was duly seconded and carried. Mr. Jeffares suggested prior to the dissolution of the meeting, that any person present ought to have the opportunity of joining, which was declared open, and close on sixty handed in their names. Officers for the ensuing year were duly elected.—A. O'N.

Horticultural Club.—The usual monthly dinner and conversation took place on Tuesday 8th, but two events hindered the attendance from being a large one—the funeral of the late Mr. T. B. Haywood and the annual dinner of the Royal Gardeners' Orphan Fund. The meeting, however, was a very interesting one, and an address was given by Mr. de Graaff of Leiden on Java, in which were very vivid descriptions of both the flora and fauna of that tropical island. Many questions were asked concerning the subjects brought forward, and much interest was excited by the wonderful account of the Bamboos, which grew to a height of 150 feet. The chairman, Sir J. D. T. Llewelyn, Bart., M.P., proposed a vote of thanks to Mr. de Graaff, which was cordially agreed to by the members present.

Mr. John Green.—We learn that Mr. John Green, F.R.H.S., managing director of the horticultural department of "Hobbies, Ltd.," Norfolk Nurseries, Dereham, has been elected chairman of the Dereham Urban Authority, and *ex officio* Justice of the Peace for the County of Norfolk.

A Unique Park.—Arizona's petrified forest—one of the most interesting natural curiosities of America—is to be protected by law and made into a national park. It lies near the Grand Cañon of Colorado in Apache Country, and the fossil trees were probably silicified in a lake holding silica in solution. One feature is a trunk 100 feet long, spanning a cañon 45 feet wide as a natural bridge.

A Contrast in Weather.—Reuter telegraphs from Chemnitz (Germany) that there was a heavy snowfall on Sunday night. In New York it is very hot. In London we are all shivering. The fruit orchards in East Kent, which were all in full blossom, have suffered severely.

Snow in May.—A South Lancashire correspondent writes that notwithstanding the far advancement of spring the weather in the County Palatine continues exceptionally cold and disagreeable, very few days of real spring having so far been enjoyed. On Saturday morning rain, accompanied by snow and sleet, which, however, melted as it reached the ground, fell for several hours.

Agitation Against Poisonous Compounds Act.—This movement has now taken an active and concrete form, and a strenuous effort will be made to secure the repeal of the Pharmacy Act of 1868. This reserves to chemists alone the privilege of selling the large quantities of weed-destroyers now vended in the market, which right the new society opposes as a monopoly, and contrary to the spirit of the Constitution. This society, whose title may be shortly stated as "The Traders in Poisons' Protection Society," has its offices at 5 and 6, Clement's Inn, Strand, London, with Mr. T. G. Dobbs as secretary, and Mr. G. H. Richards as treasurer. A strong representative committee has been formed, and a petition for presentation to Parliament has been drawn up, which all who are interested in the present movement are urgently requested to sign, when they receive the copies now being prepared for distribution in various districts. Clearly the Act of 1868 was never intended to be applied as is now sought, for at the time when it was drafted the great commercial development of the weed-killer business could never have been foreseen by the Legislature.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

A dull, cold week, with little or no sun, and a sharp frost on the morning of the 11th inst.

The Chiswick Trial of Tulips.

ALTHOUGH the report of the trial of Tulips at Chiswick affords pleasant reading, as noted by "F. W. H.," p. 396, it is a moot point what constitutes quality in a single Tulip. Take, for example, the somewhat quaint form of the blossoms of *Tulipa cornuta*, a garden species. Many persons prefer this as a flower garden ornament to any variety named in the report. The admiration of any variety is quite a matter of taste. Personally I look upon Keizers Kroon as one of the finest Tulips in existence for the decoration of gardens in the spring. Yet this variety is hardly mentioned. The superiority of one variety over another depends upon tangible results more than taste—individual—in colour.

Even in questions of colour in Tulips some might prefer a small-flowered white variety to a larger one of the same colour. I fail to see the utility of a Tulip trial; the marks given to each variety by the committee might easily be contradicted by another committee on the following day, as both can only be the personal opinion of individuals; or, perhaps, as your correspondent points out, it is a test of the Chiswick soil. After all, this is a poor result to strive for, especially when we consider the far reaching benefit such trials are supposed to bestow. At least a dozen varieties of single Tulips might be named that meet with approval by many persons which are not even mentioned in the report. Of all plants I think a trial of Tulips is of the least benefit to the general public, as there is so little chance of giving an authoritative opinion upon a subject embodying nothing beyond personal opinions.—B. W.

A National Rose Day.

I QUITE agree with Mr. William Paul and "V. M. H." about this, and that the day should be when there are plenty of Roses. But it would be hard upon our national Saint to deprive him of the national badge, and I suppose we can scarcely expect St. George to change his day. I agree also in the idea that we took the Rose badge from the Romans, just as the Britains took the dragon which had latterly supplanted the eagle as the Roman standard. Pliny speaks of "Albion, so called either on account of its white cliffs, or white Roses which greatly abound there." Certainly Roses were dearly loved of the Romans. We have not yet discovered a conservatory at Silchester, though an abundance of glass of all kinds from it is in the Reading Museum. There may possibly have been several, for there were many grand houses there, and Martial distinctly speaks of this kind of protection:—

"Lest wintry frosts should blast the shrinking fruit,
Or winds too piercing nip the tender shoot,
Through lucid walls, that check cold Eurus' sway,
Sol kindly pours the genial warmth of day."—viii, 14.

With regard to our English time of adoption of the badge, I hardly think we can get back further than Mr. Paul's "Count Egmont." He was sent about 1277 to Provins with troops to avenge the murder of the mayor of the city, and is said to have taken for his device and brought back with him to England the red Rose of Provins, which Tribut Comte de Brie had brought from Syria on his return from the Crusades.

Two well known regiments have their day for wearing Roses. The Twentieth on the anniversary of Minden (August 1st, 1759), wear red Roses in memory of that glorious day, when they fought in a Rose garden. The Fifth Fusiliers wear red and white on April 23rd, St. George's Day. The day the Twentieth observe would certainly suit the general public best. April 23rd condemns many to only artificial flowers, but still I do not see how we can throw overboard St. George. To add one to Mr. Paul's Shakespeare quotations, let us remember King Henry Fifth's exhortation—"Cry God for Harry, England, and St. George!"—A. C.

Garrya elliptica.

As a member of the Floral Committee, before which the log alluded to by Mr. Jenkins on page 373 was shown, I had an opportunity of seeing the specimen, and while regretting the reason of its exhibition, I could not help remarking that its size was not in any way remarkable for thirty years' growth. I have not tested its hardiness as an independent shrub. I am able to say that it is not positively hardy, even here in the south of Hampshire. Twenty years ago I put out two small plants, one on each side of the front door of Swanmore House, having a north-westerly aspect. Both plants made vigorous growth and

bore a heavy crop of catkins annually. In fourteen years the plants grew 23 feet high, and formed a complete bower over the doorway, and were generally admired. But, alas! a severe frost injured both plants so much as to necessitate their being cut down almost to the ground line. An alteration taking place shortly after in the structure the plants were destroyed, and have never been replaced. An extremely fine specimen used to grow (and probably does now) in the Trinity College Garden, Dublin. For covering walls on any aspect *Garrya elliptica* is a charming plant, even if it bore no catkins, as the deep green leaves have always a cheerful appearance. It is easily propagated by inserting half-ripened cuttings in sandy soil in a cold frame at the end of August, keeping them shaded for a time if the frame is stood in a sunny spot. Abundance of water at the roots and overhead during summer hastens its growth.—E. MOLYNEUX.

A London Horticultural Hall.

STRENUOUS antagonists of the proposal of the Royal Horticultural Society to provide a new garden in place of Chiswick prefer to urge the erection of a London Horticultural Hall in lieu thereof. Now I venture to ask of them and of all who support their views, do they regard the provision of a satisfactory horticultural hall in London, with offices and appurtenances, as being within the range of philanthropic effort? That is the question. It is utterly useless to discuss a subject of this nature in the gardening press unless some scheme is forthcoming that shows how the proposed hall can be provided. That such a building will ever be erected by voluntary subscription is quite out of the question. There remains then only one other course, and that is to float a London Horticultural Hall Company. But to constitute a company the promoter must be prepared with a prospectus of tangible facts, and the first course therefore is to form a small syndicate from such gentlemen as Mr. A. W. Sutton, Mr. C. T. Drury, Sir Michael Foster, Sir W. T. Dyer, and others, who appear so desirous of seeing the hall provided.

This syndicate must secure the offer of a suitable site, which must be fairly central and easy of access. Then it must obtain plans for the proposed erection, and estimates for building it. Then the council of the Royal Horticultural Society must be approached, and being offered favourable terms be induced to become tenants of the hall for its fortnightly shows and meetings, and of certain offices permanently. The council now pay for the Victoria Street offices and Drill Hall about £330 annually. No doubt that body would not mind paying a rent of £400 yearly for better accommodation. The hall could be let for other purposes on all days not occupied by the R.H.S., and might in that way produce an additional £1000 a year. If beneath the hall there were good shops and offices, those not occupied by the R.H.S. might bring in as rent £650 annually, and thus a total rental of £2000 might be obtainable. But to get such a hall a suitable site must be secured, and that would be a matter of grave difficulty. Mr. Drury has mentioned the new Abingdon Street site, on the Thames side at Westminster, about to be cleared by the London County Council. There is also the new L.C.C. street, about to be made from the Strand to Holborn—a splendid position. Both these would, however, be enormously costly.

Do those who want a horticultural hall in London realise what area would be needed? They complain that the Drill Hall is not large enough, yet the Drill Hall is, for London, a very large area; indeed, one of the finest of its kind. Really, to secure a suitable hall the frontage must not be less than 80 feet wide, and the depth 150. That means a total of 12,000 square feet. Does anyone imagine that such an area could be obtained on either of the sites named, or indeed in any central position, at a less cost than £1 per foot, or a sum of £12,000? But it would have to be realised that buildings erected on such, or any good sites, would have to be of lofty elevation. The enormous cost of ground in London now compels the erection of these lofty structures, that the outlay for the ground may be recouped. Does anyone suppose that it would be possible to stop short with a ground floor hall only in such case? Even if the ground area were covered with shops and offices, still a very lofty hall would have to be erected over them, and were other buildings of a much more lofty character erected on either side, what becomes of the hall's lighting, except with artificial aid?

To place a huge hall for exhibitions above a second tier of offices would never do, indeed is quite outside practicability. Then for the special purpose for which the hall is needed the building would have to be fitted with one or two large hydraulic lifts to enable plants to be raised to the hall, and there should be space beneath to enable vans to draw in for loading and unloading. Now supposing the promoters of a hall company had resolved to face and overcome all these difficulties, and set about floating the company, they would need at the very least a capital of some £50,000. The rental would pay rates, taxes, lighting, and salaries, and leave a small sum for a repairs fund; but whence would come dividends for the shareholders' goodness only knows. Still, there are brave men in the financial world, and with, when the war is over, plenty of money going abegging for investment, who can tell that a London horticultural hall company will not float?—L. S. D.

Rooksnest.

NEVER before has the county of Surrey generally and the district of Oxted in particular been so much discussed in the pages of the gardening press; and this has sprung from the suggestion of the council of the Royal Horticultural Society to acquire land at Limpsfield. On one point the controversialists have been unanimous, and that has been to the exceptional natural beauty of this part of Surrey. It is possible that within a given circle round Oxted station one can find scenery that of its kind is unexcelled in the British Isles, and which is as well worthy of the visits of searchers after rural charms as the more rugged crags of Scotland, or of Derbyshire. It was not, however, to examine the much debated Limpsfield site, or to travel far to view the county's beauties that the train was left a week or so ago at Oxted; the object was to see the compact gardens and grounds of Rooksnest, which, situated about two and a half miles from Oxted, is at present the residence of the Hon. P. C. Glyn, head of the great house of Glyn, Mills & Co., who are the bankers of the Gardeners' Royal Benevolent Institution.

villadom. We enter the park from the main road, and find it flanked on the one hand by a broad belt of trees crowning the rising ground known as the Warren, and on the other by undulating grass land with clumps of trees, and here and there individual specimens. The expanse is not very large, but it is in good condition, and is charmingly wooded. This drive, moreover, affords one of the best views of the mansion of Rooksnest, which, as the illustration shows (fig. 112), is of a formal rather than a picturesque character. It is somewhat low perhaps for its other dimensions, but it gains from this an aspect of solidarity, and creates an impression that within those square walls can be found handsome and comfortable rooms such as are absent from more modern and possibly more ornate erections. Through the flanking tree belt, to which brief reference is made in this paragraph, runs the Warren Path; a cool, sequestered walk that extends from the gardens near the mansion to the lodge at which we entered.

The Conservatory and its Camellias.

The conservatory, attached as it is to the mansion and built so as to harmonise with that structure, is one of those erections which gardeners

FIG. 112.—ROOKSNEST.

The gardener-in-chief, or rather the gardener and bailiff, is Mr. Jas. Friend, under whose guidance we were soon travelling over the road to Rooksnest. The route leads through the ancient portion of Oxted, which as a country village has few attractions, though it is placed in such a beautiful setting. The old church on the lower ground looks well with its foreground of gardens in all the charm of the period of the fruit blossom, and its background of hills rising abruptly to a considerable altitude. Here and there amidst the trees that clothe the slopes are villa residences, whose red bricks show conspicuously, if not attractively, from the bountiful vegetation. It is a district of villas, possibly because it is fairly accessible from London, but more probably on account of its great and thoroughly deserved reputation for healthiness.

Across the Park.

As progress is made over the road, however, the character of the surroundings change considerably, and one sees isolated, old-fashioned cottages, and the larger houses have few indications of pretentious

abhor, as it is practically impossible either to give the place a really attractive appearance or to keep plants in proper health therein. One of its lofty sides is of glass, with great stone pillars between, while the back is entirely of stone or brick. At one end is the door, and at the other the mansion, to which entrance is made by ascending a flight of steps. The central portion is occupied by a few large Palms, and the sides are partially clothed with any plants that will travel upwards satisfactorily, Fuchsias being perhaps the first favourites. Beneath the roof are climbers, with Roses as their best representatives; to secure the blooms it is necessary to mount a twenty-round ladder. Then, too, there are smaller foliaged plants, and of course when the family is in residence every endeavour is made to keep the house gay with flowers. One feature, however, it does possess, and that is found in the Camellias that hide the back wall from view. They are magnificent plants, and appear to be in the very best of health. Even when not producing, as they do annually, many hundreds of flowers, they are peculiarly handsome on account of their dark green leathery looking foliage; it would be difficult, if not impossible, if these were removed

by death or otherwise, to find other occupants that would fill the vacancy with such entire satisfaction.

The Flower Garden and Pleasure Grounds.

Of flower gardening pure and simple there is comparatively little, and the beds, which in the summer must be gay, are in the spring filled with deliciously fragrant Wallflowers to afford innumerable bunches for despatch to London. Later these will take on a more formal character no doubt, but if they are more beautiful they will certainly not contain any plants whose flowers will diffuse a sweeter perfume than did the Wallflowers a week or two back. Flowering trees and shrubs are fairly numerous about the pleasure grounds, but as vegetation is usually somewhat late on these Surrey hills, few plants were in flower. A Rhododendron here and there was showing colour in its trusses, but other attractive plants had yet to develop their buds. Close to the mansion is a rosery, but here again one would need to go in the warmer days of summer to see the wealth of flowers on the

plants are in immense masses, and in others stand as isolated specimens, and the major portion of the varieties are comparatively old. This, however, in such circumstances as the present is of little moment, as those sorts that produce fine trusses of brilliantly hued flowers are what are required, whether they be new or old. There are thousands of plants, and when one is seen rising in the form of a bank to a height of 20 feet or more, and carrying trusses on every growth, the effect is literally superb.

A Corner in Narcissi.

When one commences to speak of a corner in Narcissi or anything else, the mind of the reader will probably turn to the gigantic corners in Wheat and other commodities, that have been formed to force up prices and make the fortune (or prove the ruin) of the cornerer. The particular corner in Narcissi at Rooksnest is, however, very different from this, and has been formed with a much less questionable object in view. As a matter of fact it is a small space just without the walls of

FIG. 113.—THE LAKE, ROOKSNEST.

several plants. A charming stretch of grass, which in the summer is delightfully shaded with trees, leads to the margins of a handsome piece of water, which adds materially to the charm of the estate. On every hand there were signs of life—in some trees and shrubs well advanced, and in others only observable in the swelling buds. Evergreen trees of course are there in numbers, and play a worthy part in an attractive scene, but no names can be mentioned in the space at disposal.

A Rhododendron Forest.

It is more than likely that nine out of ten persons visiting Rooksnest in May, and being subsequently asked what they considered the finest feature of the estate, would vote for the American garden. This is what is termed at the head of the paragraph a Rhododendron forest, and it has an area of about three acres. Traversing the winding paths one passes beneath the shade of veritable giants, whose gnarled stems and handsome leafage would prove sources of inexhaustible interest even when no single flower truss could be found. In some places the

one of the kitchen gardens, and surrounded by trees, in which are thousands of Narcissi. These have not been purchased for this express purpose, but for pot culture, and having done their duty indoors have been called upon for further service in this now delightful corner. There are, of course, many varieties represented, and the available space is not yet fully occupied, and they afford thousands of beautiful flowers for cutting during April and May. Narcissi, too, are found in beds and shrubby borders, with others on the grass of banks, where they will thrive; but the bulk of flowers for adorning the mansion, both at home and in London, are drawn from that corner in Narcissi, of which a counterpart might be formed in every large garden in the kingdom where such does not already exist.

A Gay Greenhouse.

Under glass the brightest spot on the day of this visit was the greenhouse, which was simply ablaze with flowers. Instead of having them spread throughout the various structures Mr. Friend had concentrated the several flowering plants in one with the happiest results.

Of course every single plant was not in this one house—a few remained in other places, but the main supply was in the greenhouse noted. It would be no easy task to name the flower that comes to us at this particular season of the year that was not represented by one or more examples, and the simple statement of this fact will be sufficient for readers of the *Journal of Horticulture*. One, and one only, may be specified, and that is the *Schizanthus*, of which *S. retusus* was the finest. These alone would have made a singularly charming display. In the other houses there were many hundreds of plants, large and small, that are utilised for various decorative purposes both in the mansion and in the conservatory. Considerable stocks are maintained of the most valuable kinds for the object in view, and the whole of the plants were in excellent health. Chrysanthemums have long been a strong feature at Rooksnest, and the collection in the frames at the present moment looks as though it will prove well able to maintain Mr. Friend's reputation as a thorough cultivator rather than an exhibitor.

Fruits and Vegetables.

No department of the Rooksnest estate, whether in or out of doors, is better maintained or reflects greater credit on the gardener and his assistants than the fruit and vegetable section. Under glass the Grapes and Peaches and Nectarines were at the time of this visit in most creditable condition. They were healthy in wood and in foliage, and were showing for an abundance of fruit. There were the customary stages of growth in the different houses, and over all was the same stamp of excellence of management. Strawberries, too, were equally satisfactory. The outdoor fruit comprises all the kinds usually found in a well equipped garden, and it can be said for the Apples and Pears that the value of light and air for every portion of the tree is more thoroughly appreciated than is generally the case. Each branch stands well clear of its neighbour, and the advantage of openness is found in the increased excellence of the crops. Then, again, Mr. Friend is a believer in judicious root-pruning, and practises it with that discrimination which marks the expert. The bush fruits and Strawberries were all in the same commendable state. In the vegetable quarters there were signs on every hand of what is to come, with somewhat of reality in the pretty bed of Cabbages. Plans have been well laid and seeds have been sown, some in beds and others in permanent positions, and the future must prove whether the "end justifies the means," as the writer has little doubt will be the case. There are Potatoes in the frames, and Asparagus in other places—both necessary, both excellent. Probably there are other supplies, but of these the writer cannot speak from personal experience or observation, and consequently they must be passed.

Envoi.

These rambling notes must be brought to a close. They have not told all that is to be seen in the grounds and gardens of Rooksnest, but they are given as a small tribute to their excellent condition on every hand. Other visitors will go, and they will admire other features, and rightly so, for much might still be said. But my task for the moment is done, except for the fact that I must bear public testimony to the courtesy and kindness that were extended by both Mr. and Mrs. Friend to one who visited them as a stranger, but who left them, if they will permit the play on their name, as a friend.—ZINGARI.

THE COFFEE PLANT.—Nothing can be more beautiful and interesting than studies of the annual blooming, budding, growth, and ripening of Coffee in the West Indies, and its gathering and preparation for the market. The leaves, which are ovate in form, are about 4 inches long. They are produced opposite in pairs, and are dark green in colour. Similar in texture to the Mammer leaf, they have the waxen surface of the Indian Laurel. The foliage is perennial. Shooting out from the bases of these pairs of leaves, after the manner of our Cherry blooms, are seen the Coffee blossoms, almost precisely like a diminutive Tuberose, in clusters of three to six, snow white, and with an indescribable delicate, subtle, and delicious odour. For two months in spring time, says a contemporary, a Coffee plantation is simply one vast plain of white, a region of intoxicating odour, with the blue sky half shut from sight by myriads of honey-seeking butterflies, humming birds, and brilliant-winged songsters, fluttering and circling in an apparent ecstasy of revelry and delight. For nearly six months new blossoms come as the old ones disappear. Blossom and ripening berries are continuous. As the breezes snow the dying blossoms upon the ground, tiny green buttons take their place. These are the growing fruit. They change to a pale pink, then to a bright cherry, finally to a reddish purple. Then it is ripe and ready to gather.

The Season of Blossom.

THE marked feature of the latter half of the month of April was the rapidity with which vegetation came forward. During the opening weeks of the month the wind set itself about north-east and point-blank refused to move, with the result that growth made little headway, and while one section of the interested community spoke somewhat dolefully of the late spring, another thanked the north-easter for its consideration in keeping things back. While days remained dull and the wind listing, fruit buds kept wisely within their protective covers, and growers felt less fearful than if they were wide open. Peaches, Nectarines, and Apricots came out in spite of gloom and cold. Fortunately most of these had the protection of walls, and a further covering of close-meshed netting kept them safe from harm, and crops promised fairly well.

Late in April a transformation scene was brought about by the unexpected change in the weather, which was as rapid as it was remarkable. What kind of a fruit year are we going to have? is a question that everybody is asking where its culture is an important industry. At the time of writing this there is a splendid promise of stone fruit, and trees that a week previous had hardly shown signs of moving were white over with flower. Plums and Damsons are very full, but it is too early yet to make sure of a crop, because there has been as much or more bloom many times before, and all looked fair and promising. Then came the killing frost or the cold north-easterly wind, bearing on its wings hordes of aphides—pests which took sole possession of every green tip on Plum and Damson, and flowers instead of forming fruit withered and fell, and blighted hopes were as common as blighted trees. With experiences like this before us it would be foolish to prophesy, but we may at least hope that last year's scarcity of stone fruit will be changed in 1900 to one of plenty.

Perhaps at no time of the year is the country more beautiful than when fruit trees are blooming, and I know of no district where this beauty may be seen more fully than among the Kentish Cherry orchards. The individual flower has a charm of its own, peeping out as it does from among bursting tips of vivid green, but collectively they make a glorious display. We read of the brilliant flora of the tropics, but I question if any effect there can surpass the charms of mile after mile of Cherry orchards all aglow with flower. And in the district round Sittingbourne and Maidstone may be seen the capacity of this fruit when at home; for in many of the orchards are giant specimens, with mighty limbs more like those of a forest Oak than an ordinary fruit tree. How long they have been in bearing it would be hard to say, and it would be interesting to know how much hard cash they have been the means of putting into the pockets of the growers, for a good Cherry orchard is an excellent paying concern. Flowering time is only the beginning, and though early prospects please the grower, it is a later picture that bids him with the greatest satisfaction, when rich red fruits peep in quantity from a canopy of verdure, particularly if salesmen are clamouring and prices are high.

Pears, like the rest of hardy fruits, came on amazingly during the last week of April, and prospects are encouraging. On many occasions they have bloomed earlier, and perhaps more fully, but this does not insure a crop by any means, and unless some unfortunate circumstance arises there ought to be a good supply of this valuable fruit. It is yet early to say much about Apples, but the warm change in the weather has had its effect on them, with the result that they have followed more closely on the heels of the Pears and stone fruit than is usually the case. Bush fruits, such as Gooseberries and Currants, looked backward at Easter time, but the scene has changed. They are masses of green, with every shoot wreathed with fruits, and in gardens and plantations there are prospects of heavy crops.

These were impressions gathered among the fruit as April drew to a close. A few days ago it would have been impossible to give them, but Dame Nature is the most remarkable of quick change artistes. Perhaps before these lines appear in print the north-easter will have returned, and overcoats again pressed into the service. I say it may be so, for we have had bitter experiences of this kind before; but I hope such will not be the case, for the sake of the fruit and those to whom scarcity or plenty means so much.—G. H. H.

Pine Needles.—The Pine needles of South Oregon are being utilised. The needles are first boiled and then run between horizontal wooden rollers, which extract the juice. This is called Pine needle oil, which is supposed to possess medical properties. The pulp is used, says a transatlantic contemporary, as a medicated material for upholstering, and it is also said to be a good substitute for horsehair. It is said that insect pests will not live in furniture that has been upholstered with Pine needles.

Strawberry St. Antoine de Padoue.—Whilst this variety seemed to present an undoubted advance on its parent, St. Joseph, when presented to the Fruit Committee at the Drill Hall last week, the committee all the same thought that it exhibited no merit as a forced variety, indeed was for such purpose a poor variety compared with its great parent, Royal Sovereign. The committee were not informed as to whether the plants sent, each carrying one ripe fruit, were brought on in considerable warmth or at what temperature, but if such fruits could be had in the gentle temperature of an amateur's greenhouse in May no doubt the variety would be acceptable for such a purpose. Naturally the committee wish to see the new variety in the autumn, when it can be properly compared with St. Joseph, as not so much a perpetual as an autumn fruiter.—D. K.

Apple Bloom.—This has been marvellously abundant and beautiful. No trees that are fruitless can excel in floriferousness. Thousands of Apple trees as seen this spring literally garlands of flowers, and not a leaf visible. It is noticeable that the bloom is very fine—indeed, it is impossible that it could be finer or of richer hues. I do not build up great anticipations upon this immense flowering, as we all know too well how often the promise in such case, and how poor the realisation. Our best hopes are founded not on the abundance, but rather on the fine character of the bloom; the abundant rain of the winter, which gave trees so thorough a soaking; and the fact that we have not had a great Apple crop for two years. I note that Pears are setting fairly well—indeed, a moderate crop of those fruits is always best. Plums, too, so far look well, and of those and Cherries there may be almost a glut, which is no gain to anyone.

Prunus persica.—Among spring-flowering trees this, with its numerous varieties, makes a conspicuous object; and few trees are more easily grown, or can be depended on to give a better display. A great range of colour exists, from pure white, through various shades of rose and pink, to deep red. Many of the varieties have double or semi-double flowers, and are a decided acquisition, the flowers lasting much longer than those of the type. They are to be obtained either as tall standards or bushes, and in either case they make a fine show. They make admirable plants for forcing, and may be either lifted and potted in autumn or grown in pots in a similar manner to fruit trees. In the latter case they should be well fed while growth is active, and stood outside when all danger of frost is gone, so that the wood may become thoroughly ripened. Whether flowering naturally out of doors or in pots in the conservatory, the bright colouring is equally attractive.—R. G. K.

Protecting Tree Stems from Cattle.—I have not elsewhere seen practised the method Mr. John Miller employs at Ruxley Lodge, Esher, for the protection of some Sweet Chestnut tree stems from injury by sheep and horses. The trees forming an avenue in the park have stems ranging from 12 to 18 inches in diameter. They are all coated with an armour of fairly straight bean rods, some 6 feet in height, placed close together, and secured round the stems by stout galvanised wire ties three in number. When the copse cutting proceeds on the estate straight sticks are selected for this purpose when needed, although the armour usually lasts for three years. If the tree stems swell so fast that the wire ties are hurst, and that occasionally happens, other ties are fixed and drawn tight by twisting the ends with pincers. The plan adopted of getting the rods close to the trees is to place round them a stout cord, to one side of which is fixed a thick stick, and that being twisted draws the rods close and tight; then the wire bands are added, and the work is complete.—A. D.

Tomatoes as Medicinal Plants.—According to a continental journal, it appears that a Scotchman, after an experience of several years, is convinced that the daily use of Tomatoes is an excellent remedy for liver troubles. In America, also, the use of the Tomato is considered as a remedy, and prized very highly as a strengthener, and for purifying the blood.

Burning Weeds.—It is a mistake, says a transatlantic contemporary, to let weeds go to seed in the garden or around the farm, under the impression that they can be destroyed if gathered in the autumn and burned. In the first place, the job is apt to be forgotten until most of the weed seeds have been scattered. Even if a weed is burned its seeds may not be destroyed, unless a hot fire of brush is first made and the seeds are thrown on a mass of burning coals. If weeds are piled in heaps they burn slowly, and, as the seed falls to the ground it is protected from burning by the stratum of carbonic acid gas that is found at the bottom of all slow-burning fires.

Cleanliness in the Garden.—Some men can do twice as much on an acre as another. It is order, system, and cleanliness that enables him to do it. "Dirt is matter out of place." That is a true definition. I once found fault with a man, who was then a partner, that his rubbish pile contained everything from decent potting soil to broken glass, hoop iron, and empty beer bottles. He rather peevishly replied that he had no time to spare, and was glad to get rid of the stuff out of the greenhouses. That "time" excuse is the worst of all, and the man who lets his wagon stand out in the sun till the hubs are cracked, has always the most time to spin a yarn, or see how much old Bill Jones' cows bring at auction. If my friend had had a pile for stuff that was purely rubbish, and another for old soil and plants and vegetable matter that would come useful some day, it would have been time and money saved.—("Scott's Florists' Manual.")

Early Cabbages.—The race of small first early Cabbages now so plentiful has proved to be a great boon to gardeners in helping to tide over a difficult period in gardens, when all other descriptions of green stuffs run short. The seedsman in selecting his stock seems to secure one that is very true to character so that the plants heart-in simultaneously. That is undoubtedly a good feature in any stock, but it is not entirely acceptable to a gardener who in a bed of several hundreds of plants likes continuity. A big breadth turning in all at once looks well, but is not a convenience; a breadth that turns in and furnishes a supply of hearts for some three or four weeks is better. That has generally been a feature of an ordinary stock of Ellam's Early, but it seems, in spite of all the care taken, to characterise most selections. Thus it is difficult when seeing only a few hearts of the very earliest plants to determine whether the entire breadth is the same or whether many plants are sufficient.—A. KINGSTON.

"Darwin" Tulips.—That most interesting section of late Tulips grown so abundantly by Messrs. Barr & Sons at Long Ditton, evidently owe their popularity to the fact that they are almost entirely self-coloured. The section is very beautiful for garden decoration, because the breaking tendency observable in the florists' section is rare with Darwins, hence their original characters are well preserved. It is a great feature of these varieties, and the feature runs through all the late section, that once planted fairly deep in garden borders, they continue to grow, flower, die down, and reappear for generations. We like for such purpose to plant in clumps of half a dozen, always taking care that the position of each clump is marked that the bulbs be not injured by digging. Of course the bulbs do well lifted each year, as is the case at Long Ditton. But all gardeners do not care to take so much trouble. The following give a fine selection—White Queen, bluish flushed rose; King Harold, rich crimson; Corregio, bluish-lake, very charming; Peter Barr, heavy maroon; Charles Dickens, bright reddish rose; Joseph Chamberlain, blood red; May Queen, soft rosy pink; Sultan, almost black; Zephyr, rose shaded heliotrope; Professor M. Foster, rich carmine shaded vermilion; Purple King, purplish crimson shaded maroon; and Golden Beauty, brilliant yellow, though not a Darwin. All these bloom simultaneously. Of other, or Fancy Tulips, the following are beautiful—Picotee, white, heavily edged red; York and Lancaster, white flaked red; macrocephala, scarlet self; Golden Crown, bright yellow feather edged red; elegans alba, white fine carmine edge; Fulgens, crimson scarlet; Summer Beauty, white flaked and flushed scarlet lake; Buonaventura, yellow heavily flaked scarlet, a real beauty; vitellinum, lovely soft lemon; and Chamæleon, having several quaint colours.—INSPECTOR.

The Royal Horticultural Society.

Scientific Committee, May 8th.

Present: Dr. M. T. Masters (in the chair); Mr. F. Im Thurn, Mr. Shea, Rev. W. Wilks, Mr. Mawley, and Rev. G. Henslow, Hon. Sec.

Peach trees diseased.—The following report was received from Dr. W. G. Smith upon the specimens received on March 26th. He also observes that he is continuing the cultures of the fungi, as at present he is uncertain between "Fruit rot" (*Monilia fructigena*) and a form of *Cladosporium*. "The cause of discolouration of the bark of twigs is evidently a fungus which can be found in these parts. The absence of good examples of reproductive organs renders identification uncertain. In the twigs the fungus has passed the winter, and made its way into the leaf buds and flowers, causing the damage there. With a fungus such as this the course of treatment is summer spraying. Peach foliage is delicate and the spraying solution must be dilute; for example, Bordeaux mixture made with not more than 2 lbs. copper sulphate and 2 lbs. quicklime in each fifty gallons of water. The foliage should be thoroughly wetted with a fine spray, preferably that given with a sprayer like those supplied by Strawson and other firms. In winter pruning should be carried out, so as to remove all discoloured twigs. This treatment will probably require to be carried out for several seasons. The fungus might be identified if specimens of foliage were sent during the summer."

Vine leaves, diseased—With reference to those sent to a previous meeting, Dr. Masters observed that no mites could be detected by Mr. Michael, who carefully examined them; but that his opinion was confirmed that the diseased condition was most probably due to a young condition of *Gloeosporium*.

Larix occidentalis.—Dr. Masters showed young cones of this species from Oregon, characterised by having green bracts, the European Larch having them of a red colour. It is described as the finest timber tree of N.W. America. It was discovered by Douglas, who mistook it for the European species.

Observations on Limpsfield.

UNTIL quite recently nothing was heard in gardening circles about Limpsfield. Its name has, perhaps, never been mentioned in horticultural journals except, possibly, by a casual reference to Titsey Place, the seat of a chief county family—the Leveson Gowers. Lately, however, Limpsfield has come very much to the front, as a site there has been recommended for the establishment of a new experimental garden of the Royal Horticultural Society, in connection with a National School of Horticulture, to be purchased and supported by certain County Councils. It has been twice decided with practical unanimity at general meetings of the Fellows that the old garden at Chiswick is to be relinquished, and a new garden formed in commemoration of the approaching centenary of the Society. As the Society's term of possession expires in twenty years, the governing body has concluded that the sooner a site for a new garden is selected the greater will be the amount derivable by sale of the residue of the present leasehold for building purposes; hence the desire to secure the best obtainable site elsewhere as soon as is consistent with a wise decision.

After attending the special general meeting on April 25th, and hearing there such widely divergent views, especially on the nature of the soil at Limpsfield, three persons decided to visit the site for the purpose of forming an opinion upon it. These self-constituted examiners were Messrs. A. Dean, G. Gordon, and J. Wright. There are some cardinal points that seem to demand consideration in choosing a site for a new national garden—namely: 1, accessibility; 2, climatal considerations; 3, situation and shelter; 4, configuration; 5, soil; 6, water; 7 (in this particular case), a School of Horticulture.

Accessibility.

For practical purposes the "new Chiswick" must be quickly and economically accessible from the seat of government—viz., London. Most Fellows of the Society visit the metropolis periodically, and whether the garden should be twenty or thirty miles east, west, north or south, they would have to do so to reach it, as few quick trains stop at stations within such distances of the terminus. The Limpsfield site can be reached from Victoria in an hour by rail and road, but not by all trains, the special daily cheap train in summer is ten minutes slower.

Climatal Considerations.

The first of these is immunity from smoke-laden fog, not for a few years merely but for a century. For this immunity we must have regard to altitude and surroundings. As to the former the upper part of the site inspected is over 500 feet above sea level, the lower part 300 feet; as to the surroundings, there are on two sides hundreds if not thousands of acres of common land, which can never be built upon, the remainder being purely agricultural land—arable, meadow, and

coppice—a district as "truly rural" as could well be imagined, and miles away from any town. The air is probably as pure as could be found anywhere, while there is nothing to obstruct the full flood of light between Limpsfield Common and the English Channel.

Situation and Shelter.

From an æsthetic point of view it would not be easy to imagine a panorama more beautiful in its way than that which is swept by the eye from the upper portion of the ground over the far reaching and well wooded area of Kent and Sussex—a lovely typical English landscape. But what of the "shelter" which for the purposes of a garden is all-important? With a grand natural elevation along the north, curving partly down the west and tree-clad hills on the east, it is doubtful if anything more complete could be imagined, for it is shelter without shading in the least what it is desired to screen. Except perhaps along a portion of the west side what may be described as the frame of shelter, seems perfect, though possibly intersecting screens might be desirable if the eight fields were transformed into a garden.

Configuration.

Generally the land from the horseshoe-shaped shelter of the northern extremity above indicated slopes somewhat sharply to the south till it reaches a footing of nearly flat fields; but in addition there are a few acres presenting easterly and westerly aspects with easy slopes, or sufficiently so for fruit cultivation. Thus the site, as a whole, is the exact reverse of a "dead level of uniformity," and certainly picturesque effects could, if desired, be produced in the upper portion, while cultivation on the irregular surface and varied aspects would give results of an educational character.

Soil.

It may be stated at once in reference to this almost vital factor in the whole case, that there is plenty of room for differences of opinion. There are two forms of soil on the Limpsfield site—one in which sand preponderates over the clay, as in the upper portion; the other in which clay predominates over the sand on the lower level. A gardener who had experienced a more than ordinary share of backache in working very strong land would prefer the lighter section at Limpsfield; a gardener who had struggled for years against drought, in a dry light medium, would prefer the stronger. In one of the semi-starved fields on the site there is a cogent object lesson. Either some manure has been shot down and lain for awhile, or there has been a rubbish fire. Whatever the fertilising medium, the effect of it is sufficiently striking, for a deeper, richer, and more robust growth of Wheat could be scarcely conceived. The land has not been well farmed, but the reverse, and only requires sound cultivation—tillage and nutriment—to grow better fruit and vegetables than can be grown at "Old Chiswick" by any man.

An ideal soil is supposed to consist of 50 to 70 per cent. silicious and calcareous sand, 20 to 30 per cent. clay, 5 to 10 per cent. pulverised limestone, and the same amount of humus. But where is such land to be found? The sand at Limpsfield is presumably not calcareous. It consists of the washings and drifts from the sandstone on the "heights" above; but there are millions of tons of chalk near the station, and humus can be imparted by natural manure. The soil is improveable; it cracks now in drying, and bakes somewhat, but the cracking is preventable by surface tillage, and the lumps are easily smashed to powder when dealt with at the right time. The upheavals of moles are powdery, and the under soil tested wherever we might, even dug from the bottom of plough furrows, the clay, after some heavy showers, did not in one instance "cake" under compression, but broke into particles, reminding of the lines of Thomas Tusser, written more than 300 years ago:—

All gravel and sand
Is not the best land;
A rotteny mould
Is land worth gould.

How much "gould" this Limpsfield land is worth is for others to determine, but it is understood it was bought by the present owners for between £80 and £90 an acre. As it contains no gravel, and a good deal of it not too much sand, while in texture the strong part is "rotteny," it might perhaps have suited old Tusser.

Water.

As 80 per cent. in bulk and weight of our garden crops consists of water, and some of them a good deal more, not another word is needed to enforce the necessity of a full and constant supply in gardens. True an excess in the soil is injurious, and a few patches of the land in question are no doubt wetter than is good for them. But there is a great *per contra*—a veritable treasure—in the form of what appears to be regarded as an everlasting spring. This is towards the base of the southern declivity, where a pumping station is provided for meeting the demands of the extensive convalescent home of the Charing Cross Hospital above. The overflow passes in a constant stream right through the proposed garden, and meanders away, through copse and meadow, into the distant river Eden. Whoever has control of this stream through the grounds can hold the water up where it might be needed, and by scouring the main outlet below, and rendering

operative choked drains or grown up ditches, can liberate the pent-up water, as required, from most if not all the lower land. This would unquestionably improve it, though doubtless provision would be made for aquatic and bog plants, as could be made most easily. This fine water supply is one of the most valuable features of the property, if the land through which it finds its way as best it can should be converted into a garden. The water courses and fences have been woefully neglected.

The Suggested School.

At the top of the proposed garden is the comparatively new Caxton Convalescent Home, established for the benefit of sick printers. It seems it has not been popular with them, as the "comps" wish to be near the sea. In connection with a well equipped garden it would with additions make a fine School of Horticulture, and it is to be supposed that before purchasing the building the County Councils would satisfy themselves scientifically, through the agency of the professors at the Wye College, that the land which the Royal Horticultural Society has on offer is suitable for the object in view, and this would also be satisfactory to the Fellows. The college, it is presumed, would contribute annually for the educational use of the garden.

It is not in the least to be understood that the foregoing remarks are intended to imply that the Limpsfield site is the best obtainable for a "new Chiswick;" nor are they penned with the object of either combating or supporting any other views, for the visit was planned before other views were published. The observations simply represent the convictions of one who earnestly hopes that no mistake will be made in choosing a site for a "new Chiswick," wherever such site may be.—ONE OF THE TRIO.

I HAVE read with much interest the various reports which have appeared in the *Journal of Horticulture* on the Limpsfield site for the proposed New Chiswick, and, as I presume that before long the Fellows will be asked to decide definitely for or against this site, I shall be very much obliged if you can find room for this letter in your next issue.

Whatever the merits or demerits of this site may be—and to some extent the differences of opinion are doubtless due to the fact that even heavy and wet land looks much more promising in May than it does in winter—the fact remains that it is nearly three miles from a railway station, with bad approaches.

Even supposing the soil were all that is claimed for it, it must be obvious that to transform a heavy arable and pasture farm into a garden, where horticulture of every kind shall be carried on in a manner worthy of our national society, would entail an enormous outlay of capital. In addition to this transformation of arable and pasture land into a garden, houses heated in the most approved manner must be built in which plants of all kinds may be grown; also vinerias, Peach and Fig houses, &c., &c., must be erected and afterwards maintained at an annual cost compared with which the expense of Chiswick is insignificant.

Those who favour the scheme are doubtless prepared to admit all this, but I venture to think that the Fellows generally are unwilling to see all the existing funds applied to such a purpose, together with a further sum vastly exceeding the present resources of the Society, and which can only be raised by voluntary donations. Before sanctioning so great an outlay we ought very closely to understand what advantages would accrue to the Fellows, also what (if any) would be the gain to horticulture generally.

Unless in one garden we have all branches of horticulture carried out on a scale almost regardless of expense, what hope is there that students would be likely to choose the New Chiswick as a school for gardening, rather than avail themselves of the opportunities already afforded by a course of training at Kew, or in gardens such as Frogmore, Sandringham, Gunnersbury, Syon House, and many others; or by employment in Messrs. Rivers', Messrs. Bunyard's, and Messrs. Pearson's nurseries for the culture of fruit under glass or in the open; at Messrs. Veitch's, Messrs. Sanders', Messrs. Bull's, and elsewhere for Orchids, &c.; at Messrs. Paul's, Messrs. Turner's, Messrs. Cant's, and elsewhere for Roses, &c., Messrs. Kelway's for herbaceous plants, &c., &c.

The value of the Chiswick trials of vegetables has already been discussed sufficiently to show that such work is far more completely done in the trial grounds of the large seed houses. What material advantages, then, can result from this vast outlay of capital and money required for the annual up-keep?

But there is another point which the Fellows will readily grasp, and have perhaps already seen—viz., that with the establishment of a new Chiswick at the cost which the Limpsfield site must necessarily entail, all hope of a National Hall of Horticulture disappears, at least so far as the present generation of horticulturists is concerned. If the Society appeals to the country to finance the Limpsfield scheme, it cannot again appeal for funds to acquire a new hall and headquarters of the Society.

Now that it has been shown by so many writers that Chiswick can be made to answer all the actual requirements of the Society so far as

a garden is concerned, the council will earn the most unqualified approval and gratitude of the Fellows were they generously to forego their New Chiswick proposals—at least until such time as it has been proved impossible to raise the money required for a Horticultural Hall.

But the most important factor in the case is that, judging from his letter in last Saturday's "Gardeners' Chronicle," it appears not unreasonable to hope that Baron Schröder may again be willing to lend his aid, which would at once go far to insure the success of any well devised scheme for acquiring a new hall. If the Baron's letter may bear this interpretation, can we sanction a scheme which would deprive the Society and horticulture generally of what is universally admitted to be the fittest way of celebrating the centenary of the Royal Horticultural Society?

The thanks of all horticulturists are due to Baron Schröder for coming forward at a time when his counsel and support were never more welcome.—ARTHUR W. SUTTON.

Notes on Figs.

THE first crop fruit of early forced trees in pots has, or soon will have, all been gathered, when the loose portion of previous mulching should be removed and a fresh supply of well decomposed manure or rich compost applied, which will encourage root action and aid the trees to perfect the second crop. In this they may be assisted by top-dressings of chemical manure, applying a little over the mulching at intervals of a fortnight or three weeks. If the trees have become infested with red spider or scale thoroughly cleanse them by means of an insecticide and a stiffish brush. The syringe should be used freely twice a day to keep red spider in subjection, always using clear soft water, as that containing lime or iron is liable to cause a deposit on the fruit that greatly detracts from the appearance. Water and liquid manure will be required liberally at the roots, not allowing them to lack moisture or giving it excessively, yet the supplies must be adequate and well sustained. It is advisable to leave the second crop fruit low down on the growths, and keep the points of the shoots free and well exposed to light.

Planted-out trees started at the new year have the first crop Figs ripening. Syringing in such case must cease, and a superabundance of water or moisture about the house be avoided. A little air admitted constantly at the top of the house, and continued until the fruit is perfected, with a free circulation of warm air whenever the weather is favourable, is necessary for good finish and high quality. The trees, however, must not lack water at the roots, as this prejudices the health of the foliage and the second crop fruit, therefore supply water to the border when the fruit commences to ripen, especially where the trees are large and the root space limited. The fruit should be kept perfectly dry, well exposed, with its apex as far as possible to the light, and be quite ripe before gathering, unless it is to be packed, when it must be gathered a day or two sooner.

Successional Fig houses require attention betimes in stopping the young shoots at the fifth or sixth leaf to induce a sturdy habit and growths at the right place and proper length for furnishing the trees with bearing wood evenly in every part. Crowding, however, must be avoided by removing growths that cannot have ample room for development and exposure of the foliage to light and air, rubbing off such shoots early. When the growths are sturdy and short-jointed, the terminals or extending shoots should not be stopped, and only a judicious number of the side shoots be pinched to form spurs.

Strong-growing and long-jointed sappy wood is best removed, but if the trees produce much of that they ought to be marked for lifting and root-pruning, or they may have the growth checked by taking out a trench down to the drainage, cutting the roots at about one-third the distance from the stem the branches cover of trellis. This will give a sudden check, and the trees respond by concentrating their forces on reproduction, and are aided in developing the fruit by the fibrous root action induced. Do not give so severe a check as to cause the leaves to fall, but when done judiciously summer root-pruning is better than winter, as a year is gained. Attend to syringing the trees twice daily, and water abundantly at the roots as often as required, employing weak liquid manure, especially where the borders are small.—GROWER.

BACTERIA.—A magazine devoted to scientific topics, sagely remarks that the bacterium has something else to do in the economy of Nature than in originating maladies. It continues the topic by noting a paper in a French magazine by M. Matruchot, on the agency of bacteria in forming the colours of flowers. It is something to check the microbean craze of the popular press in regard to the supposed viciousness of these humble vegetable organisms. It is true, says Mr. Meehan, that they are operating in innumerable directions—but the number that are associated with disease are very few—and even these few, if the animal be healthy, are digested by the gastric juice as easily as would be an oyster. The majority, indeed, are essential to our health and happiness.

Sweet Pea Bicentenary Celebration.

SELDOM, if ever, has a proposed exhibition of a special flower received such general support as that of the Sweet Pea, to be held on July 20th and 21st next. At the present time, about two months ahead of the exhibition and conference, financial matters are in a most satisfactory condition, while the applications for schedules serve to indicate the widespread interest that is being taken in this popular flower and its exhibition. On Friday, the 11th inst., the Executive Committee met at the Horticultural Club, Hotel Windsor, Mr. G. Gordon, V.M.H., presiding, when it was reported by the hon. sec., Mr. Richard Dean, V.M.H., that the whole of the north nave of the Crystal Palace would be devoted to the forthcoming exhibition, and that a suitable room would be provided for the conference proceedings. The trade displays will form a border around the competitive exhibits, and these latter will be relieved by tables of plants. One great improvement promised is that the tables will be draped with green baize, and consequently there will be no unsightly array of boxes and other impedimenta below the flowers.

In connection with the conference, arrangements were made for papers to be read as follows:—"The History of the Sweet Pea," by Mr. S. B. Dicks; "The Evolution and Improvement of the Sweet Pea," by Messrs. J. Eckford and C. H. Curtis; "Classification of Sweet Peas," by Mr. W. P. Wright; "Sweet Peas in America," by the Rev. W. S. Hutchins; and "Some New Points in the Cultivation and Decorative Use of the Sweet Pea," by Mr. H. Dunkin. Fifteen judges, including three ladies, were selected for the competitive exhibits, and it was decided the Exhibition Committee should judge the trade exhibits. Applications for space must be made to Mr. R. Dean, Ranelagh Road, Ealing, as the entire arrangements for the show are in the hands of the committee. Intending exhibitors and others will be interested to learn that a cold luncheon will be provided at the Crystal Palace on July 20th, tickets 5s. each, including wine. Breakfasts will be provided earlier in the day at 1s 6d. per head.

With a view to securing as large an attendance as possible the executive committee is calling a general committee meeting for four o'clock on Thursday, May 24th (the second day of the Temple Show), at Anderton's Hotel, Fleet Street. It is hoped that all committeemen in town will make a special effort to attend and receive the report of the executive body.

Flowering Trees and Shrubs.

BEAUTIFUL as are the several flowering trees, with many others, to which brief allusion was made on page 376, the shrubs that are grown for the attractiveness of their flowers are even more popular. This arises from two facts; 1, the greater diversity of flower and habit, and 2, the greater utility of these smaller growing plants. There are few if any places so completely stocked that it would be impossible to find room for a number of shrubs, whereas with flowering trees the matter is different. Many of the latter do not attain to sufficient size to be decidedly ornamental for some years after planting, while shrubs are immediately effective if they are employed judiciously. So wide is the selection, and so different are the characteristics of the plants that can be drawn within the category of flowering shrubs, that a thoroughly complete and yet representative choice is well nigh impossible, but a few may be referred as standing absolutely in the front rank for general utility.

Taking into consideration that we are now in the month of May the place of honour must be given to Rhododendrons, for these are essentially flowers of May. In every garden they are represented, but in varying degrees. In some places they are grown to form complete gardens with the nearly related Azaleas; while in other estates one finds immense banks of them bordering sweeping lawns of soft, green turf. For such positions as the latter it is of course necessary that the lawns be of considerable extent, or they will appear overwhelmed by the gorgeousness of the shrubs that flank them. Generally speaking the commoner varieties are used for banks, but where what are usually termed American gardens are contemplated the vastly improved newer forms ought to be chosen. To enumerate the best varieties is beyond the scope of general notes such as these, but planters may safely leave the selection in the hands of some of our first-class nurserymen who keep their stocks right up to date in all respects. Rhododendrons are, of course, employed to an enormous extent, but more Azaleas might advantageously be planted, as they have a beauty and grace that cannot be excelled by any other kind of flowering shrubs. With these a more careful selection is requisite, as some are much hardier than others, and the tenderer ones must

obviously have the most favoured situations as regards shelter from keen frosts and biting winds.

The Ribes or Flowering Currants make a really charming display in the later spring months, and they are quite indispensable in borders or beds of shrubs. Individual specimens of the older forms are not particularly attractive, as the colours are inclined to be "washy," but the newer varieties, such as *atrosanguineum*, are splendid, either planted singly, or what is unquestionably preferable, in clumps. *R. aureum* on a wall is singularly pretty at the end of April, but with me it has not proved satisfactory in the open, though possibly it might be so in more favoured positions. Of *Garrya elliptica* I have nothing to add to my note on page 395, and I am waiting with much interest the views of other contributors to the *Journal of Horticulture* as to its hardiness; certainly if it will succeed in the open it should be grown as well for its handsome leafage as for its catkins.

Where is the garden without its share of Lilacs? Such a one would, I venture to affirm, be very difficult to find. This is as it should be, for amongst the several varieties we have now a wide range of colouration, and fortunately the majority of them are deliciously fragrant. Some, of course, are sweeter than others, but one can hardly go far astray. In gardens where flowering shrubs are cherished the Weigelas are almost invariably accorded a conspicuous position, as their distinctive beauty is acknowledged and appreciated. Yet there are gardens in which Weigelas are represented by perhaps one or two miserable specimens, that are barely worthy the name of plants. In the grounds of Gunnersbury House, and also of Battle Abbey, there are some of the finest specimens of Weigelas that it has ever been my lot to see. In each of these places the branches are simply loaded with flowers, which hang down with the weight of their charming burden. A really good form of *W. rosea* is very hard to excel, especially when the colour becomes so intense as it does in some soils and situations. *W. alba* is also peculiarly well adapted for certain positions in the borders.

Differing in every respect from either of those that have been enumerated are the Brooms, of which again the selection is wide. For certain positions on banks the Spanish Broom is absolutely unrivalled, and I have in my mind at the moment of writing a bank at Lockinge that is simply gorgeous when the plants are flowering. Personally, I know no place where the Spanish Broom has been utilised to greater advantage. There are other Brooms differing in colour from the Spanish, and perhaps not quite so showy; but, at the same time, they are of the utmost value for certain positions. Some of the forms of Gorse, too, must not be despised, as they are distinct from all other shrubs, and will luxuriate where the majority of plants would do no more than eke out a wretched existence. Then, again, we must in justice place in the forefront of flowering shrubs the Berberis, which in several species and varieties is really superb. There was a time when *B. Darwini* was the prime favourite, but now it must take second position to *B. stenophylla*, which as a flowering shrub is absolutely perfect. The long arching branches clothed in bright yellow inflorescences produce a unique effect, and one which never fails to attract close attention and elicit expressions of admiration. This plant is admirably employed in the gardens of Syon House, where full advantage has been taken of its striking individuality.

There is certainly no garden from which the Mock Oranges (*Philadelphus*) can be excluded; they produce, especially when such varieties as *P. Gordonianus* is employed, a grand display, and, fortunately for shrub lovers, one which cannot be provided by any other plant. The wanderer from garden to garden comes across many instances of their value for ornamentation, but, so far as I have seen, the specimens in the drive of Summersbury Lodge, near Guildford, would be difficult to excel. This, so far as my experience goes, is not a particularly satisfactory town plant, but I have only tried it under the most unfavourable conditions with respect of fogs and smoke, so that too condemnatory terms would not be justifiable. Who does not grow in town and country the fragrant *Mezereon*, or to apply to it the botanical name *Daphne mezereum*? It may not be showy when compared with others that have been enumerated, but it has a modest charm that enchains attention and insures the admiration of almost everyone. Add to this a most pleasing perfume, and no one can marvel for one moment at the plant's popularity. It is a shrub as well for the cottager's garden as for the princely estate, and thrives alike in both.

Amongst shrubby plants that might be more freely planted in gardens are several of the *Spiræas*, which are decidedly handsome. In

Fig. 114.—WEIGELAS ROSEA AND ALBA.

the gardens of Swanmore House there is a magnificent example of *Spiraea* (*Exochorda*) *grandiflora* that forms a lovely picture when in full bloom. In addition to this there are others, which, if not possessed of such striking beauty are undoubtedly deserving of inclusion in all well appointed pleasure gardens. But how can the list be completed? There is such a galaxy of beauty that several articles would have to be written ere all could find a place. In brief, however, may be noted *Cydonia* (*Pyrus*) *japonica*, *Andromeda speciosa* and its varieties, the *Forsythias*, *Kerria japonica* fl.-pl., *Buddlea globosa*, the *Deutzias* in variety, which, though they may not be indispensable, are at any rate most desirable adjuncts to every garden in the kingdom.—F. ROWE.

[*Weigela rosea* and *alba* are depicted in fig. 114, but our artist has by no means done justice to their beauty.]

The Young Gardeners' Domain.

Bits for the Bothy.

(Concluded from page 316.)

As the time approaches for bidding farewell to bothy life, most young men, probably, take more serious views of things in general, and their own prospective positions in particular. All right thinking ones will certainly do so. There is, and it goes without saying, much anxiety about the future, but there should be something more than that, and ere the final plunge into responsibility is made a self-searching glance into the mirror of truth may possibly prevent false reflections arising hereafter. It has been the endeavour to impress through the whole course of bothy life the value of personal inspection and mental stocktaking, but never before has occasion appeared to demand so exacting a survey as now. Perhaps some reader can picture life—a gardener's life—as one bound up in three volumes, the first of which is nearly finished—all but closed. Opened hereafter it may be, altered it cannot. Oh! Young comrades, the youngest of you just commencing the early chapters, ere concluding, you are asked to consider how much this means to you. I would that in the years to come, when the silence and the calm of life's evening are stealing on, this first volume should be to you very pleasant reading.

Many a smart foreman feels, doubtless, quite equal to the charge of a garden similar to that in which he as yet holds a subordinate position. It is a natural sequence of circumstances that he should do so. Nevertheless he may very probably have to begin his rule in a much smaller one, and one apparently below the par of his ability and experience. This so frequently happens that it would be well for all at this stage to take the matter into serious contemplation; for, anomalous as it may appear, a young man may be less inclined to do himself justice in the small place which circumstances have forced upon him than in a more extended sphere of operations. In short, a measure of contumely springs up for the situation which he considers to be beneath him. In any case the first command of whatever degree may well be regarded by the young head as a trial ground from which proofs are expected of what he professes. As many must start in a small garden or protract their stay in bothydom longer than may be expedient, there should be some consolation to them in reflecting that from such comparatively obscure situations some of the leading places of the day have been filled by men who, under apparently adverse circumstances, have contrived to find or create the opportunity of showing their worthiness of being thus elevated.

All things come to those who wait, if they will work whilst waiting instead of dissipating their energy and discounting their ability in half-hearted measures and vain regrets. Eventually the fittest come to the front, and the fittest stop here. That we live in a practical age is shown by the practical way in which some of the best posts are being filled, and, although few young men may agree with the writer, the opinion has long since obtained that these low grade gardens, if the term may be used, are fine finishing schools for young commanders. There are little things in bothy life which during that term are possibly small enough to be overlooked, or only thought of to be despised, but at the critical stage of leaving it are of sufficient weight to turn the scale in a man's favour when competing for a situation. Competing, it is said, for in spite of many situations being filled privately, over the dinner table as some have remarked, it cannot be overlooked that a quiescent kind of competition has taken place, and the selected one has been pretty keenly criticised, and comparisons made although unknown to himself.

So far as ability and general good character go there may be nothing wanting. Some young men, however, show a magnificent contempt for the little refinements of speech and manner, and will bravely tell you that by their abilities as a gardener they stand or fall. This is so. But how much easier a man is fitted into a higher position, and how much better he fits it when these little angularities of character, which strike the eye and ear of cultured people with whom from henceforth his duties keep him in touch, are pruned away. The

worst examples are those in which a consciousness of these failings brings an awkward constraint, placing one who may be an excellent gardener and a good man in his worst light. This should not be. Surely a man who takes such infinite pains with his plants to exemplify in them the highest possible cultivation, does not do justice to himself by totally disregarding the amenities of life. Is a man less than a plant that he should ignore his finer instincts?

It is sincerely hoped that our foreman long ere leaving the bothy will be impressed with the force of this personal cultivation and the weight it undoubtedly carries when he is leaving it. A notable characteristic of some of those grand old gardeners of the past was a certain refinement and courtliness of manner which one seldom meets with in the hurry and crush of later days. Men, manners, and methods have changed with the times, but as gardening is steadily growing into a factor of the first importance in the world's economy and will ever remain the purest of human pleasures, so should it be the endeavour of each ministering hand and responsible head to elevate their vocation to the position it is justly entitled to. Never was gardening, itself, more highly esteemed than it is to-day, but it is a fact that gardeners, somehow, are not as a class recognised in ratio to work which demands such high intelligence, elaborate forethought, and unremitting attention. The reason for this may be to some extent inexplicable, yet not wholly so, for "our remedies oft in ourselves do lie which we ascribe to heaven." That each young foreman as he is called to the front may go forth strong with faith in his future, firmly believing that he can, if he chooses, be a unit of power in the ever-spreading gardening world of the great British Empire, is the earnest hope of—THE OLD BRIGADIER.

Fruit Forcing.

Vines.—*Early Forced Houses.*—Where the Grapes are ripe, afford fire heat only to prevent the temperature falling below 60°. Admit a little air constantly, with a free circulation when the weather is favourable. Do not allow the border to become dry, but keep it moist, and mulch with rather dry, sweet litter, both to prevent excess of air-moisture and keep the soil from cracking. A little moisture in the atmosphere is not injurious to the Grapes, and is highly beneficial to the foliage, which must be kept clean and healthy. Fumigation may be resorted to if thrips appear, repeating in the course of a few days. For red spider there is no better plan than vaporisation with sulphur placed in water, not allowing the receptacle to become dry. Even sulphur placed in shallow saucers and covered with water or kept moist in the full sun, as on shelves near the glass, gives off fumes inimical to red spider and prejudicial to fungoid germs.

Successional Vineries.—As little fire heat as is consistent with the steady progress of the crops should be employed, for with sun heat and abundance of atmospheric moisture more real benefit is gained in a week than in a month with the aid of fires during dull weather. The Vines being in full growth the temperature may be allowed to rise to 90° to 95°, closing the house at 85°, employing fire heat only to maintain a day temperature of 70° to 75°, and to prevent it falling below 65° at night, yet 5° less will do no harm but good when the weather is cold. These remarks apply only to Vines in full growth and swelling their crops, as those that have the Grapes approaching ripening should have a rather free circulation of air, those more advanced being kept cooler and drier. Air should be admitted very early in the morning, as the sun's rays acting powerfully on the condensed moisture formed on the foliage during the night usually cause scorching, unless air has been previously admitted.

Watering the borders must be attended to as required, not having stated times. Some loams are naturally very loose, sandy, or gravelly, while others have opening material added, such as lime rubbish, oyster-shells (calcined) and charcoal, which makes them sieve-like. The consequence is the greater need of water, besides the danger attending the finish of Grapes grown on such soils through insufficient supplies of water leading to attacks of red spider, and thin foliage, which does not assimilate and store nearly as much essential matter as the stout leaves on Vines in a firm substantial soil of a rather retentive nature. Such soil will require water less frequently, but in no case must there be lack of moisture at the roots throughout the swelling periods.

Liquid nourishment is also more frequently required by loose and light soils than by compact and retentive ones. All will need top-dressings of some approved fertiliser, three times at least being advisable—1, When starting the Vines; 2, when the Grapes attain to thinning size; and 3, when the berries commence to ripen, supplying 4 ozs. per square yard at each dressing and washing in lightly. If more stimulation or support be needed, supply the manure oftener; this is

better than increasing the quantity each time and at long intervals. A light mulch is of great advantage in keeping the soil uniformly moist at the surface and supplying nourishment. Cow manure is best for light porous soils, and horse droppings are excellent for those of medium and retentive natures. Both are better sweetened, that is, not used quite fresh, but thrown into a heap and turned a time or two as if preparing for a Mushroom bed, and heavy mulching should be avoided, an inch thickness sufficing, adding to it from time to time so as to maintain that depth or very little more. This will not deprive the soil of the essential atmospheric air, especially if the material be used, as it should be, in a rather lumpy state.

Late Houses.—In some places the work now on hand in thinning the berries is considerable, and will continue for some weeks, as in many instances the Vines are only in flower. In the latter case maintain a minimum temperature of 65° to 70°, 5° more for Muscats, shaking the Vine twice a day to distribute the pollen, which will be sufficient for all but the shy setters, and these ought to be artificially fertilised, going over the bunches carefully with a camel's-hair brush, and supplying pollen where it is deficient from those varieties that afford it freely. All the large berried and free-setting varieties, such as Gros Colman and Gros Guillaume, should be thinned whilst they are in flower, or as soon as set, and with those that are liable to have closely set berries it is advisable to thin before the flowers expand, as a practised eye can tell which flower will set by its vigour, and the removal of the weaker strengthens those left wonderfully. While the Vines are in flower moderate moisture, with a rather free circulation of warm air, is desirable. It is also inadvisable to stop or remove laterals while the Vines are in bloom, but when the berries are fairly set remove superfluous laterals and pinch as required, both to prevent overcrowding and concentrate the supplies of nourishment on the Grapes.

Planting Growing Vines.—From now to the early part of June is a good time to plant out those raised from eyes in February or March and grown in pots or turves. The roots need not be disentangled, yet turf-raised Vines are better than potted ones, as they form a straight yet fibrous root, and are not so prone to descend deeply as those turned out of the pots with the ball entire. Firm the soil well about the balls or turves, giving a good but not excessive watering with water at 90°, and mulch with about an inch of short and rather lumpy manure. Maintain a rather humid atmosphere, and shade from bright sun until the Vines become established.

Strawberries in Pots.—There must be no lack of moisture at the roots of Strawberries, as when the sun is powerful the fruits are apt to have the skin dried, and they do not swell properly afterwards; the fruits are also better for a slight shade from the fierce rays of the sun. After the fruits commence swelling a brisk moist heat is essential, applying liquid manure liberally until the fruits change colour, when it must be discontinued, giving less water at the roots. Admit air freely whenever the weather is favourable, avoiding drying currents. Thin the fruits well on late plants, especially the late varieties. Water the plants twice a day, and in bright weather three times at least. Liquid manure may be given at the afternoon watering.

The Kitchen Garden.

Artichokes.—Globe Artichokes have developed sucker growths far more than are wanted this season. If all are allowed to remain none will be strong, and a short crop of small flower heads be the result, whereas if the growths are reduced to about three in each group these will grow strongly, branch freely, and develop a long succession of large succulent heads. Feed the older plants freely, supplementing occasionally with soakings of liquid manure and a heavy mulching of strawy manure. Young plants recently separated from old stools and carefully planted on heavily manured deeply cultivated ground should be kept well supplied with water at the roots during dry hot weather, and they ought then to produce a few acceptable, because late, flower heads. Seedlings raised under glass and still in 5-inch pots, should be quickly hardened and planted out 2 feet apart in rows 3 feet asunder, on well manured deeply cultivated ground.

Beet.—Birds are very destructive among the young plants this season. Where this trouble is experienced late thinning is desirable, and if occasional dusting with soot and lime while the leaves are damp in the morning will not deter the birds, a single line of black cotton should be stretched just over the rows. More seeds of a selected variety sown at this late date may result in the production of a serviceable crop. Where birds are not troublesome early thinning of plants should be resorted to, not waiting till they have already weakened each other. Medium sized roots can be had by leaving the plants not more than 8 inches apart. The Turnip-rooted type will transplant readily.

Carrots.—The seeds of these in common with various other vegetables have germinated well, and where sown thickly much thinning will be necessary. This can be most expeditiously done while the plants are small. The Horn variety need only be thinned to 2 inches apart, drawing more when the roots are large enough for use, ultimately leaving those reserved about 4 inches asunder. The intermediate and long rooted types should be thinned more severely directly they are large enough.

Onions.—In gardens near to towns, and also farm buildings, sparrows have cleared off the plants wholesale. A single line of black cotton,

as advised in the case of Beet, seems the only remedy. Where there is no such interference the thinning should take place when they are quite small, or when they can be drawn with the least amount of disturbance to those left. If 12 inches or so are allowed between the rows a serviceable crop of roots can be had by thinning to about 4 inches apart, allowing an additional 2 inches if large roots are desired. A light surfacing of soot is an excellent dressing for Onions, applying this and stirring it in when rain is expected.

Parsnips.—For large roots of these there is little demand, the smaller and more acceptable class of roots being obtained by sowing somewhat late (April), and by lightly thinning those rows that were sown much earlier. Do all necessary thinning early, leaving the plants about 8 inches apart, while 12 inches is none too much space if exhibition roots are wanted.

Turnips.—The strap-leaved varieties, including Early Milan, do not form large leaves. These should be thinned early to 6 inches apart, drawing the roots later as fast as required, or when near the size of overgrown Radishes. The stronger growing Snowball type should be thinned to 12 inches apart, or they may fail to "bulb" properly.

Hoeing Among Crops.—Directly the rows of seedling plants are well defined hoeing between them should commence. It is not merely a question of getting rid of weeds, but the ground ought to be frequently stirred with Dutch hoes, this keeping it loose and open, also destroying all advancing weeds.

THE BEE-KEEPER.

Seasonable Notes.

It is several years since there was such an abundance of bloom, not only on the fruit trees, but also on the different hardy trees on which the bees work. The Plums are now nearly over, and thanks to the bees fertilising and the fine weather which prevailed whilst they were in bloom they appear to have set well. True there have been frosty nights and high winds, but in this district (South York hire) it has not seriously affected them. The next fortnight will decide the question whether an abundance of fruit will follow; so far the prospects are decidedly good.

Apricots have set remarkably well, bees having played an important part in fertilising the blossoms. The result is, they must be severely thinned if fine fruit is expected. If gardeners would realise how beneficial bees are in the fertilisation of their fruit trees, there would not be a garden in the country without a stock or two of bees. Gooseberries and Currants are also well set, and as the former are now well in leaf they will withstand several degrees of frost without any harm happening to them. This is the great advantage that Whipham's Industry has over other varieties, as it bursts into leaf as soon as the flowers are opening, which protects the blossoms from frost.

There are not many stocks in the country strong enough to store a surplus from the fruit blossoms. It is not only from the fruit trees that bees obtain their stores at this season, the meadows and woods are carpeted with flowers, many of them yielding an abundance of pollen. One has only to observe the bees as they return laden to their hives with the pellets of different coloured pollen on their legs to realise how numerous the flowers are on which they work.

We have mentioned in previous notes the advantage bee-keepers derive from planting the different varieties of Willows near the apiary. They all yield an abundance of pollen, and at the present time the bees are working more freely on them than on any other non-fruiting tree. The Sycamore and Wild Cherry, of which there are numerous trees near our apiary, are much frequented by the bees on account of the honey and pollen they produce. The former yield an abundance of honey of poor flavour. It is, however, not stored in quantity, as the bees are increasing in strength every day, and thus require an abundance of stores. Extra combs or frames of full sheets of foundation should be given to colonies that are crowded with bees.—AN ENGLISH BEE-KEEPER.

Gardeners' Charitable and Provident Institutions

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 175, Victoria Street, S.W.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. Brian Wynne, 8, Danes Inn, Strand, London, W.C.

- All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Vine Leaves (Inquirer).—We could not find any of the insects referred to in your letter on the under side of the Vine leaves, they being so fragile, if any were present when the leaves were packed, as to have completely disappeared in transit. With the exception of some slight eating of the leaves, or damage to the tissue by a bruise, there was nothing the matter with them, they being quite healthy and free from pests. On the Vines there were examples of the common "springtails," which are usually somewhat abundant where there is vegetable or animal matter in a state of decay, and even in damp earth. They are sometimes a trouble in houses, rasping the stems of young Cucumber plants. They are readily destroyed by dusting the soil with quicklime, or water at 110° to 120° may be used, a light sprinkling sufficing.

Vine Leaves Rusted (W. C.).—The leaves are simply rusted, there being no evidence of malignant vegetable or animal organisms. The rust or small excrescences on the under side of the leaves have been caused by keeping the house somewhat close, and then admitting air in such amount as to suddenly provoke evaporation from the foliage. The parts affected perform their offices very imperfectly, and sometimes cause the leaves to assume a sickly and diseased appearance, and interfere, though not generally materially, with the elaborating and assimilating functions. There is also some scorching, certainly due to neglect of ventilating before the sun had acted powerfully upon the house, and the leaves are very thin in tissue. We can only suggest earlier and more judicious ventilation, the night temperature being kept at 60° to 65°, and 70° to 75° by day, increasing to 80°, 85° or 90° with sun heat, air being admitted between 70° and 75°, and the ventilation correspondingly increased with the advancing temperature, and never given so as to lower it.

Melon Plants Collapsing (T. M.).—The roots of the specimen appear quite sound and free from pests, but at the collar there was a slight enlargement, with small light coloured excrescences. The stem immediately above the collar was somewhat contracted, and on this part were small pustules. We have long been acquainted with this affection, which is akin to browning or "branure" in Vines. The slight enlargement on the root stem just within the soil yielded both a specimen of root stem eelworm, *Tylenchus obtusus*, and the mycelial hyphæ of a fungus, possibly that of the Kidney Bean rust, *Glaeosporium Lindemuthianum*, the small pustules on the stem just above ground being apparently due to this parasite, though no fructifying bodies were observable. Possibly the fungus passes up the stem as plasma, and is thus apt to be confounded with the browning organism, *Pseudocommis Vitis*; but whether one or the other, or both, the effect is to stop the ascent of the sap at the nodes of the leaves, which collapse. The disease has become very prevalent of late years, especially in Cucumbers grown for market, the conditions of culture adopted being highly favourable to pests. The disease receives considerable check from dressings of a mixture of air-slaked lime and soot in equal parts by measure, it being sprinkled on the surface of the soil at the rate of a good handful to the square yard, repeating occasionally. Lime applied to the soil is useful as a preventive, and in the early stages of attack Little's soluble phenyle, 1 in 1000, or a fluid oz. to 6½ gallons of water, has given good results.

Black Spots on Clerodendron Leaves (Idem).—The black pustules on the under side of the leaves are those of some unrecognised species of *Phragmidium*. The only remedy is to remove and destroy the worst infested leaves and spray the whole plant with methylated spirit diluted to a safe strength, which must be ascertained by experiment. Petroleum emulsion may also be used in a similar manner, or any of the advertised fungicides in accordance with the instructions.

Sweet Peas Defective (J. O. H.).—The seeds are very indifferent, only the larger ones being perfect; the others, more than half, are not only very small, but devoid, in the specimens examined, of embryos or young plants, consequently they cannot grow. There, however, was no trace of disease, the seeds being simply imperfect, possibly due to ineffective fertilisation. Only the good seed will grow, hence the seeds sown will not come up properly in relation to the number placed in the soil. The seeds do not appear too old for germination, though that is a matter for testing.

Non-setting of Tomatoes (J. C. A.).—The chief cause of Tomatoes not setting their fruit is excessive vigour, combined with a too close and moist atmosphere, the plants not having enough air, and possibly light. Artificial and even cross-fertilisation may be useful in some cases, also rapping the footstalks of the flowers on the trusses when the blooms are fully expanded to liberate the pollen, but unless this be perfect, also the pistillate organs, there can be no good result ensue by any of the three processes. We do not see in what way the water could affect the blossom and setting of the fruit, though it may be largely impregnated with or contain organic matter, which would probably be corrected by adding sulphate of lime or gypsum to it, about an ounce per gallon counteracting the tendency to an excess of organic acids and their consequent causticity. Caustic soda, 98 per cent. purity, may be procured of any chemist to order, there not being any necessity to use the term "Greenbank" in this country.

Covering Bank at Tennis Lawn (F. R.).—The position and height of the bank is such that there are few suitable plants. Nothing would answer your purpose as well as a rather rapid growing Stonecrop. Of these perhaps the best would be *Sedum spurium coccineum*, which would form a dense carpet of green, with crimson-purple flowers in June and July. It is so dense that the balls would be readily seen. The ordinary variety has blooms, too, like the colour of the balls. Even brighter would be *Sedum reflexum*, with showy yellow flowers. These are, however, more elevated above the foliage, and might hide a ball thrown with some force. Either would soon cover the bank if planted a few inches between each plant. It would need practically no attention, while *S. reflexum* would require to have the blooms cut off after they were over. Either would hold up the soil of the bank. *S. reflexum* would look better in or out of bloom than *S. spurium coccineum*, but the latter is easier to keep in order. Other capital plants are unsuitable on account of their hiding the balls. *Helianthemum*s would make a delightful bank, but the blooms are usually past early in the day. *Hypericum calycinum* is good, but would hide the balls.

Pear Tree Leaves Blistered (P. J. P.).—The leaves are infested by the Pear-leaf mite, *Phytoptis pyri*, which causes red blister-like spots to appear on the upper surface before the leaves are fully expanded, and later on they change to yellowish green, then to a dark brown colour, presenting finally a dead, dry, brown or black, corky appearance. The spots occur either singly, scattered over the surface of the leaves, or coalesce, forming large blotches which sometimes involve a considerable portion of the leaf. The mites live in galls set up by the deposition of eggs in the tissues in the spring. Spraying or syringing the trees with a solution of petroleum emulsion has a good effect, repeating occasionally from early spring up to the middle of July, the mites infesting the young leaves as produced. Any badly infested leaves or points of young shoots that can be spared may be removed and burnt, but it is not wise to defoliate the tree or trees to an excessive extent. The spraying or syringing should be practised about every fortnight or three weeks, with 2 ozs. of the emulsion, usually called petroleum, or paraffin softsoap, to a gallon of water. The pest may usually be prevented by a single spraying of the trees in winter with petroleum emulsion diluted with seven parts of water, it being important to apply the solution thoroughly and whilst the trees are dormant.

Beetles in a Vinery (Idem).—The insects are the grooved or black Vine weevil, *Otiorhynchus sulcatus*, which is very destructive, both as beetles and as larvæ or grubs. The beetles feed on the young shoots of Vines, Peaches, Apricots, and other choice fruit trees; and are particularly fond of the young fronds of *Adiantums* and many other Ferns. The larvæ are usually most injurious to the fleshy or young roots of Vines, Raspberries and Strawberries, and frequently do great harm to potted plants in greenhouses, especially to *Cyclamens*, as well as to the roots of a great variety of plants in gardens. The beetles feed at night, when they should be sought for and destroyed, but they fall very readily off their food plants when these are shaken, or when a light is brought into their vicinity; hence it is advisable to lay cloths or papers, or to invert an open umbrella in the daytime beneath, and at night shake the plants; then collect the beetles without delay, as they sham death for a short time only, and place in a vessel containing hot water or a little paraffin oil. This practice persisted in will greatly reduce their number, if not clear them.

Book on Orchids (H. W.).—It would have been much easier to answer your question had you given some indication of the price you were prepared to pay for the book. "Williams' Orchid Manual," price 25s., is a standard work, and may be obtained from Messrs. B. S. Williams & Son, Upper Holloway. In a more popular style, and at a lower price (about 3s.), you will find "Orchid Growing for Amateurs," by Mr. H. A. Burberry, late Orchid grower to the Rt. Hon. Jos. Chamberlain, excellent. The cultural details in this book are the result of many years' practical experience, and are thoroughly reliable. The publishers are Messrs. Blake & Mackenzie, School Lane, Liverpool.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (G. H.).—1, A fairly good form of *Cypripedium barbatum* much resembling *C. b. biflorum*; 2, *C. b. Crossi*, true. (T. A. J.).—1, *Spiraea japonica*; 2, Rose Harrison's Yellow; 3, *Deutzia gracilis*; 4, *Fritillaria Imperialis*; 5, *F. Imperialis* var.; 6, *Cydonia (Pyrus) japonica*. (W. W. B.).—1, *Prunus (Cerasus) Padus*; 2, *P. nana*; 3, *Genista racemosus*; 4, *Phlox setacea*; 5, *Lycium europæum*. (K. S.).—1, *Berberis Darwini*; 2, *Doronicum plantagineum* var.; 3, *Magnolia Soulangeana*; 4, *Berberis stenophylla*.

At the Other Side.

THROUGH the courtesy of a friend we have been allowed to see a packet of most interesting pamphlets and leaflets, all relating to practical agriculture, but not English agriculture—they come from the far-off islands of New Zealand, where there is a most active department of agriculture under the direction of the Hon. John Mackenzie. From his name we should guess he is of Scotch parentage, and certainly he and his department are doing actively good work "at the other side."

The first papers we take up relate to dairying service, cheese and butter factories. It appears the Government support and find work for a dairy commissioner (we wonder where Mr. Lonsdale's commissioner is and what he is called?) We turn to the dairy work first because we have just seen in a neighbouring town excellent New Zealand butter. Now we find these good folks are in advance of us. They are getting rid of the small dairies up and down the country, from which the output of butter, though good, is never uniform. They have grasped the fact that it is more economical and more profitable to work the butter and cheese trade by co-operation, and factories are springing up all over the land. There is one very suggestive remark that caught our eye at once:—"Government advances to dairy companies. For particulars of this means of raising money see the Dairy Industry Act, 1898." That, to our mind, speaks volumes. It is a difficulty to find the money privately for the erections of this nature, but we feel sure that if there were an available fund here in Old England for such a purpose, only too gladly would it be applied for. Private enterprise is all very well, but, so far, it has not answered at home, else why the lack of factories and creameries?

The Government inspector finds the same faults existing there as he would do were he to visit us, and he lays great stress on certain points. He finds much fault with the quality of the milk, and considers this is owing, in a great measure, to the bad keep cows receive in the winter before calving. The cows are not in condition either to produce good milk or strong healthy calves. As the milk is paid for in proportion to the butter fat it contains, this is, to say the least of it, bad policy. He also suggests that a rug for the cows in winter would be a great addition to their comfort and health; certainly it would be a better way of retaining heat than by keeping them too closely packed in ill-ventilated byres. Then, again, he milk flavour is not all that can be desired. He suggests several causes for this, the main one being strong-tasted weeds and coarse herbage, the unclean state of the milking sheds, or the low condition of the cow induced by excessive scouring. We, ourselves, have often got hold of very moderate-flavoured butter in summer, butter that should have been

DAHLIAS. PLANT NOW!

If you want the best send to DOBBIE, Rothesay

A few of many expressions of satisfaction received during May. The best is always the cheapest in the long run.

OXFORD—Your Dahlias turned out splendidly with me last season. My Pompone cleared the boards wherever exhibited.—E. G. C. C.

LINTZ GREEN—Dahlias to hand; I am very much pleased with them. They are strong healthy plants, and were splendidly packed.—S. S.

PENANG, S.S.—I received the Dahlias in fine condition, and am exceedingly well pleased with them and with the care you took in packing and sending them.—A. O.

ARDGAY—I received box of Dahlias safely. They are very fine sturdy plants.—W. M.

HULL—I am again delighted with the Dahlias received from you.—A. B.

STIRLING—Dahlia plants came to hand in very fine condition. Many thanks for the kind and careful manner in which the order was executed.—J. D.

HEXHAM—I received the Dahlias all right and am very much pleased with them. They are a grand lot of plants.—T. W. J.

PONTYPRIDD—Many thanks for Dahlias, which arrived in splendid condition. The packing was a treat.—H. C.

LEICESTER—You will be glad to know that I was first at Abbey Park Show last year with Dahlias in the open class.—W. H.

HAVERFORDWEST—I was very much pleased with the Dahlias I had from you last year. I took first prize with six blooms from the six plants I got from you.—W. G.

For perfect results everybody should obtain direct from Raiser, whose stocks are pure, and with proper culture success certain.

Collections from 1/6 upwards.

(See particulars in Catalogue.)

Orders now booked for plants in splendid mixture, 2/3 per 100, post free.

Prices of named kinds on receipt of requirements.

CULINARY PEAS!

Eckford's Culinary Peas are positively UNRIVALLED for FLAVOUR and CROPPING CAPACITY!

PURE VEGETABLE SEEDS!

Collections to suit all requirements at 105/-, 63/-, 42/-, 21/-, 12/6, 7/6, 5/-, 2/9. Carriage paid to any Station in the United Kingdom.

CACTUS DAHLIAS!

Strong plants of leading varieties at 4/6, 7/6, 10/6 per dozen. List free on application.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!

PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties.

PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLAKED VARIETIES.

VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! **ILLUSTRATED Catalogue & Cultural Notes POST FREE.** If you love Gardening send for one.

HENRY ECKFORD,
SEED GROWER, WEM, SHROPSHIRE.

ORCHIDS.—ORCHIDS. QUANTITY IMMENSE.

By Special Appointment to H.R.H. the Prince of Wales. Inspection of our New Range of Houses IS CORDIALLY INVITED BY

HUGH LOW & CO., BUSH HILL PARK, MIDDLESEX.

"West's Plant Grip Stakes."

Everlasting double grip Stakes for instantly staking all plants. Send post card for Illustrated Catalogue.

"WEST'S PATENT VAPORISING FUMIGATOR.—Best and Cheapest, for being made of brass and zinc, will last for years. The stove only requires a little spirits to saturate the asbestos, so may be used thousands of times without wick or further trouble. Price complete with Stove and Bottle of Spirits, 9d., post free, to vaporise up to 2500 cubic feet.

"WEST'S EXTRACT OF NICOTINE" is guaranteed pure Nicotine, and three times as good as the best compound. It is not a compound, i.e., not a chemical substitute for Nicotine, but will make a compound equal to the best if desired at 2½d. per 1000 cubic feet. Price 7d. per Sealed Bottle of 1000 cubic feet, post free.

"WEST'S INSECTICIDE" can be proved to be the Best and Cheapest by sending for a free sample box.

"WEST'S POWDER WEED KILLER."—Best and cheapest. Guaranteed satisfaction. 1/6 tins post free.

For particulars of West's Patent "Ivory" Plant Labels, Soft Metal Tree Fasteners, S. M. Plant Clips, Gardener's Fountain Pen, Powder Diffuser (for dusting powder on plants), Wall Nails, Flower Grip Holders, Plant Pot Crocks, West's Fertiliser, West's Lawn Sand, West's Mealy Bug Destroyer, &c., see Illustrated Catalogue of West's Patent Garden Specialities, post free. Samples free, postage extra. All goods made on the premises of C. E. West, and delivered free.

"Orchid Culture," 3rd Edition, postage 3d.; gives full particulars of the cultivation of Orchids.

THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS

Journal of Horticulture.

THURSDAY, MAY 24, 1900.

The Journal of Horticulture can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

The Temple Show.

HAPPY thought it undoubtedly was, no matter in whose mind it originated, to secure the only large open lawn within the precincts of the City of London, and convert for a brief space of time the

historic Temple Gardens into a veritable Temple of Flora. There, now for a period of a dozen years and more, has been grouped in the space adjoining the grand promenade on the Thames Embankment the richest and most diversified display of plants and flowers to be seen anywhere towards the close of May.

On the occasion of the summer shows of the Royal Horticultural Society the floral treasures of many lands may be said to be concentrated for a short but brilliant period in the heart of the greatest city of the world, and those of its teeming population who can do so enjoy the feast provided. Numbers of visitors, too, from distant parts of the country, not to say beyond its shores, assemble on the great occasions. The Temple shows bring together all that is most beautiful, rare, and meritorious in Nature assisted by Art—the art of scientific production and splendid cultivation. When this is so it follows that not only the best society in London flock to admire the display and choose what they desire to possess, but the great multitude interested in flowers and other products of gardening skill join to crowd the tents and luxuriate in the feast of beauty therein provided.

In bringing together such gatherings as the Temple Show, and the great show of British grown fruit held at the Crystal Palace, the Royal Horticultural Society is doing much towards acting up to the substance of its charter. We find this to have been granted for the promotion of horticulture, and it would be difficult to conceive of one better form of education, or promotion, call it which you will, than these exhibitions. The visitor whose interest is centred in orchidaceous plants finds in the Temple examples superior to his own, and he has learned a lesson from this simple fact. He has now an object before him which he strives to reach

No. 2635.—VOL. CII., OLD SERIES.

—namely, to grow his plants equal to those that have stirred his admiration and aroused a keen enthusiasm to excel. As with Orchids, so with all of the many other products seen—each serves as a whip or spur to urge the grower ever onward towards better things.

In addition to the honour that must be accorded to the Royal Horticultural Society for its excellent work in bringing together these displays, a meed of praise must be given to those people who produce the component parts of the exhibition. These comprise both owners and growers, who for the credit of British horticulture spare no expense in time or labour, and put forth their best efforts to insure the Temple Show reaching nigh on to perfection year by year. But there is still another factor in the great machine, without which the Temple Show would cease to be. This is the permission given by the Benchers of the Inner Temple to the Council of the Royal Horticultural Society to use their beautiful gardens for this purpose. It is a privilege that must be cherished, for there is not another place in London that, all things considered, equals the Inner Temple Gardens for the great annual show of the leading horticultural society of the world. The weather at the time of opening on Wednesday was very wet, but the tents were crowded with visitors during the afternoon.

In this, the thirteenth show in the Temple Gardens, we find comparatively little alteration in the general arrangement of the five commodious tents. Year after year the applications to the authorities for space become more and more numerous, and with equal regularity each applicant has to be cut down in amount. The constant though slow influx of new exhibitors necessitates compression, which is the cause, perhaps, of some disappointment on the part of those who support the society not only at this gathering, but also at the fortnightly Drill Hall meetings. But the result is always the same—a magnificent display of Orchids, Roses, greenhouse and stove plants, hardy flowers, fruits, and vegetables. Quite the finest produce that can be grown is now to be seen in the Temple Gardens, and, as usual many thousands of visitors will enjoy the spectacle.

As the Benchers of the Inner Temple cannot see their way to permitting more ground to be covered with canvas the tents remain as heretofore. We have given the dimensions of them before, but not for some years, and we may therefore repeat them now. The row of three on the Embankment Walk are, commencing at the principal entrance, respectively, 110 feet, 150 feet, and 170 feet long by 28 feet wide each; the central tent is 120 feet long by 40 wide; and the largest of all is 150 feet long by 60 feet wide. These figures are not given as precisely correct, but as approximate thereto, and are sufficiently accurate to indicate the enormous amount of space that is available for exhibits, and which, great though it is, could be filled twice over if room could be found for more tents. But in the general opinion it is large enough, as the extension of space would probably lead to no more desirable result than the mere duplication of many of the plants and flowers shown.

We need not institute comparisons with previous exhibitions, but will rather be content with saying that the present show is generally speaking equal to any of its predecessors, and is in one or two directions distinctly superior. There have been fears that the unfavourable weather would seriously prejudice the excellence of the display; such, however, does not prove to be the case, for though some products would have been the better for an additional three or four days of genial conditions, the greater portion are in that state of perfection to which only the sound knowledge of the British gardener could bring them. We must now turn to the particular exhibits in the various sections, and shall, as is our custom, commence with the Orchids.

Orchids.

There can be little doubt that the most popular section of this magnificent show is the one devoted to Orchids. Nowhere else in the country, or out of it for that matter, can such superb collections be found, and while we miss in this, as in previous shows, one or two exhibitors who rank amongst the foremost as Orchid growers, there yet always remains sufficient to please the ordinary visitor and even the specialist. We yearly look to amateur and professional growers for the products of their skill, and though this is the thirteenth

show, they have never yet failed to respond to the call. We found in the Temple Show on this occasion a very high average of excellence, and in a few instances plants that were decidedly above the usual standard. As has been the case in former years, the entire central staging was devoted to Orchids, and even this does not suffice, for we found in the next tent (No. 4) other collections that go far towards taking this unique display to absolute perfection. Without further preamble we will turn to the several exhibits, taking them in precisely the same order as they are arranged, and not according to their individual excellence.

Messrs. F. Sander & Co., St. Albans, occupied the position of honour in the great Orchid tent, and seldom has it been more worthily filled. The plants were in that excellent condition which ever characterises the Orchids from St. Albans, and the beauty of the arrangement is quite on a par with the quality of the products. The group was splendidly diversified, and comprised many species, hybrids and varieties of fine form. We may quote as amongst the most conspicuous the Cattleyas. Some of the choicest of these were *C. Mossiæ* Princess of Wales, *C. M.* Our Queen, *C. Mendeli* Countess, *C. M.* Prince Edward, and *C. M.* *crispata*, *C. Schroderæ* The Baroness, *Lælio-Cattleya callistoglossa excelsa*, *Miltonia Bleuiana grandiflora*, *Cypripedium Gertrude Hollington*, *C. bellatulum*, *C. Lawrenceanum*, *Oncidium concolor*, *O. ampliatum majus*, *Cattleya Lawrenceana*, *Zygopetalum Perrenoudi*, *Dendrobium Victoria Regina*, *Batemannia grandiflora*, *Odontoglossum excellens Victoria*, *Dendrobium Boxalli*, several *Odontoglossums* including forms of *crispum*, *Adrianæ*, and *Pescatorei*, *Bulbophyllum barbigerum*, and a handsome plant of *Cœlogyne Dayana*. Messrs. Sander & Co. made an edging of a plant of the *Vanilla* in fruit.

The small group of Orchids from Mons. le Marquis de Wavrin, Château de Ronsele, Somerghen, Belgium, was composed wholly of

FIG. 115.—CATTLEYA CITRINA.

varieties of *Cattleya Mossiæ*, some of which were of exceptional excellence. The most meritorious were *C. M.* *fastuosa*, *C. M.* *candidula*, *C. M.* *olivacea*, and *C. M.* *Ronseleana*.

Exceptionally beautiful was the collection of Orchids from Messrs. Charlesworth & Co., Heaton, Bradford. Regarded as a whole it was singularly attractive, as well by reason of the effective arrangement as by the average of merit of the individual plants. High as is the reputation of this Yorkshire house, it is well sustained in their

latest metropolitan effort. Particularly good were the Cattleyas, including *C. Schröderæ* albens, *C. S. alba*, *C. S. heatonense*, numerous forms of *C. Mossiæ*, comprising *Reineckiana* superba, *C. Wm. Murray*, *C. citrina* (fig. 115), *C. Skinneri* alba, and *C. Schilleriana* heatonense. There were also several splendid forms of *Lælia purpurata*, with *Miltonias*, *Masdevallias*, *Oncidiums*, *Phaius Crawshawiana*, *Lycaste Ballæ*, numerous *Odontoglossum crispum*, *O. Adrianiæ Imperiale*, *O. mulus*, *O. hystrix elegans*, *Phaius Charlesworthi*, *Cymbidium Lowianum*, *Dendrobium Phalænopsis Schröderianum* heatonense, and others.

As we have remarked in these columns on more than one occasion, Mr. J. Cypher does not leave Cheltenham for London often enough to satisfy the majority of orchidists. In every plant and every flower we see the stamp of the best of culture, and the taste that is displayed in staging the plants adds greatly to their beauty. Probably the best feature was made by the Cattleyas, amongst which the most prominent were *Lawrenceana*, varieties of *Mossiæ*, *Schilleriana*, *citrina*, *Mendeli*, *Schröderæ*; *Lælia purpurata* in numerous light and dark varieties was superb, as were the specimens of *Dendrobium nobile*, *D. transparens*, *D. atro-violaceum*, *D. Victoria Regina*. In addition to those enumerated we observed fine *Masdevallias*, *Odontoglossums*, with *O. Cervantesi decorum* (fig. 116); *Cypripediums*, including *niveum*, *Miltonias*, and *Sophranitis grandiflora*.

Located for many years at Clapton, Messrs. H. Low & Co. were compelled a comparatively short time back to migrate to Bush Hill Park, and if we may take the plants shown in the Temple Gardens as a criterion, the move was a wise one. The leaves of the plants simply glow with health, and the flowers have that size, substance, and colour that can only be secured under the most favourable conditions. Of more than average merit were *Cattleya Skinneri* alba variety, *Cypripedium l'Ansoni*, *Odontoglossum excellens*, *O. Pescatorei*, *Vanda Agnes Joachim*, *O. crispum* (fine), *Cattleya Mendeli* Mafeking, *Cypripedium Lawrenceanum* Hyeana, *C. Aylingi*, *Phalænopsis Brymerianum*, and the new *Lady Rothschild*, *Cattleya Mossiæ* in variety, and *Odontoglossum crispum* *Britannia* superba.

We should not like to say for how many years Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., V.M.H., Burford Lodge, Dorking, has occupied his present position in the large marquee. Sir Trevor most ably supports the Temple Show, and in doing so places before the general public such a collection of Orchids as could scarcely be equalled from any other private garden in the country. There were specimens ranging from the minute botanical curiosity to handsome plants in large pots carrying flowers of the greatest excellence. We cannot pretend to enumerate them all, and will name *Cœlogyne Dayana*, *Cattleya Mendeli*, *C. Lawrenceana*, *C. Mossiæ*, *Lælia purpurata*, *Masdevallia Harryana acanthifolia*, *Calanthe veratrifolia*, *Oncidium Marshallianum*, *Miltonia Bleuiana nobilior*, *Oncidium concolor*, *Dendrobium cœleste*, *Aërides Houlettiana*, *Spathoglottis aureo Veillardii* (fig. 117), *Dendrobium Jerdonianum*, *Miltonia vexillaria*, *D. infundibulum Jamesianum*, *D. atro-violaceum*, *D. Nestor*, *Masdevallia Harryana violacea*, *Cypripedium Youngianum*, *C. Eleanor*, *C. ciliolare*, *Epidendrum radicans*, *Dendrobium linguiforme*, *Maxillaria Houtteana*, *Phalænopsis Luddemanniana*, *Odontoglossum crispum* in variety and others, *Lælio-Cattleya highburyensis*, *Miltonia flavescens*, and a number of botanical Orchids that create great interest.

Some few weeks ago we had the pleasure of seeing the Orchids at Clare Lawn, and were then more than pleased with the clean healthy growth that is secured by Mr. W. H. Young for Sir Frederick Wigan. The promise of excellence then observable was more than fulfilled by the plants exhibited, and particularly worthy of note were *Epidendrum falcatum*, *E. Wallisi*, *Lælia purpurata*, *Miltonia vexillaria*, *Cattleya Skinneri* alba, *Cymbidium Lowianum*, *Phalænopsis amabilis*, *Cypripedium bellatulum album*, *Miltonia Bleuiana*, *Cattleya Lawrenceana* Hyeana, *C. Mossiæ* Bronze Queen, *Cypripedium barbatum*, *C. W. H. Young*, *Odontoglossum citrosimum*, *Cattleya Mossiæ excellens*, *Miltonia vexillaria* Memoria J. D. Owen, and *Dendrobium Parishii*.

As representative of the county of Hampshire we had Mr. E. Carr, gardener to W. A. Gillett, Esq., Fair Oak Lodge, Eastleigh, who apparently only comes to London with Orchids at Temple Show time, as we do not remember the Fair Oak plants being at the Drill Hall. The plants were effectively staged, and comprised Cattleyas, Oncidiums, Odontoglossums, Cymbidiums, Lælias and others in variety. All the plants were finely grown.

Mons. Florent Claes, Brussels, Belgium, has made for himself an

enviable reputation with *Odontoglossum crispum*, and the plants in the present Temple Show will rather improve this than otherwise. They had wonderful growth, and were carrying handsome spikes. The varieties are numerous.

Another Belgian exhibitor was found in Mons. A. A. Peeters Brussels, who showed *Lælio-Cattleya Ceres*, *L.-C. Canhamiana superba*, *L.-C. Herode*, *Odontoglossum crispum* Stanley, Mrs. F. Peeters, *punctatum*, and *Vigeri*, with *O. Adrianiæ Victoria Regina*.

Several feet of staging had been reserved in this position to accommodate the small exhibits of new and rare Orchids. Amongst the contributors were Mons. Jules Hye Leysen, who had three or four plants in an ugly case; Mons. Ch. Vuylsteke and E. Ashworth, Esq., both of whom staged *Odontoglossums*; H. Little, Esq., who staged a magnificent *Lælia*; and Messrs. J. Veitch & Sons, who sent a handsome bigener.

The last Orchid group to be noted in the big tent was that of Messrs. Stanley Ashton & Co., Southgate, who were represented by a varied and interesting collection. *Cattleya Mossiæ*, *Odontoglossum citrosimum album*, *Cymbidium Lowianum*, *Oncidium concolor*, *Odontoglossum crispum* in variety, *Lælia purpurata*, *Miltonia vexillaria*, *Cypripedium Lawrenceanum*, and *Oncidiums* are conspicuous.

Adjourning now to the smaller central tent we must accord the honour of premier position to Messrs. Lucien Linden, Brussels, who

FIG. 116.—ODONTOGLOSSUM CERVANTESI DECORUM.

have a superb exhibit. This Belgian firm has evidently mastered all the secrets of Orchid culture, as was amply demonstrated by the plants in the Temple. In pseudo-bulb, leaf and flowers the plants were practically perfect. The choicest were *Odontoglossum crispum* *Impératrice des Indes*, *c. eminens*, *c. radiosum*, *c. Figaro*, *c. confetti*, *c. Domino*, and *c. exornatum*. There were also several unnamed crispums, as well as of other species. The Belgian firm also contributed *Miltonia vexillaria*, including both pale and rich coloured forms.

Messrs. Backhouse & Son, York, arranged a small group of Orchids with *Asparagus* as a groundwork. There was a fine central specimen of *Lælia purpurata*, with Cattleyas, *Dendrobiums*, and *Odontoglossums*.

Probably the Orchid grower who lives nearest to the Temple Gardens who exhibited is Mr. J. Clarke, gardener to Ludwig Mond, Esq., Avenue Road, Regent's Park. The collection was a small one, but was composed of clean, healthy plants well arranged of *Cymbidium Lowianum*, *Lælia purpurata*, *Odontoglossum crispum*, *Brassia verrucosa*, *Cattleya Mossiæ*, *Miltonia vexillaria*, *Cattleya Mendeli*, *Dendrobium atro-violaceum*, and *Cattleya Schröderæ* alba.

We usually find Messrs. B. S. Williams & Son, Upper Holloway, located in the large marquee, but on this occasion they had a change, and were in the smaller tent. Their group was a most attractive one, as the well grown plants were so tastefully displayed. *Vanda suavis* was superb, as were *Lælia purpurata*, *Vanda tricolor*, *Calanthe veratrifolia*, *Odontoglossum crispum* in variety, *Cattleya Mossiæ*, *Anguloa Clowesi*, *Odontoglossum luteo-purpureum*, *Oncidium concolor*, *Cypripedium Gowerianum magnificum*, *C. Warnerianum*, *Odontoglossum Pescatorei*, and *Cattleya Skinneri*.

Roses.

The queen of flowers made a splendid display, for nearly all the southern trade growers were represented, and the fact that the plants have been grown for the most part in cold houses is sufficient guarantee of their beauty, for while there were many large formal specimen plants, there were others in every shape to take off the stiffness; in fact the Roses at the show, whether plants or cut blossoms, were equal to any of former years, and the various exhibitors displayed much taste in the arrangement of their groups, there was an entire absence of heaviness so often noticeable in groups of this character.

Mr. C. Turner, Slough, staged at the end of the tent a huge bank of glorious Roses in the pink of condition. The chief bank was wholly composed of specimens, interspersed with Acers, while tall specimen standards were placed behind. Palms were also utilised to hide the canvas walling of the tent. Notable were large plants of Mrs. J. Laing, Celino Forestier, Juno, Spencer, La France, and numbers of Crimson Rambler, with a few small Roses for the front, such as Perle d'Or, Madame Abel Chatenay, Souvenir de M. Eugène Verdier, Mrs. S. Crawford, and L'Innocence: a bright and attractive exhibit without a weak plant.

The Cheshunt Roses from Paul & Son, The Old Nurseries, were relegated to their time-honoured corner. The eye rested here on a grand exhibit. The flowers and specimen plants were not only of first-rate quality, but the arrangement was most pleasing, the tall pillar Roses producing quite an artistic display. The specimens included good plants of Mrs. J. Laing, Celine Forestier, Chas. Lawson, Rev. Alan Cheales, Madame de Watteville, The Rev. J. B. M. Camm, a splendid new Rose; Antoine Rivoire, Caroline Testout, Innocente Pirola, and Ulrich Brunner. The exhibit contained some fine standards, such as Marquis Litta, Souvenir de President Carnot, Maréchal Niel, Haileybury, a good coloured Rose, and the Rev. Alan Cheales. The pillar Roses relieved the formality of the exhibit, Crimson Rambler and Psyche forming the chief feature. The exhibit also included some unnamed seedlings of great promise. The edging of Maidenhair Fern gave a pleasing finish.

Messrs. W. Paul & Son, Waltham Cross, contributed a magnificent exhibit of Roses in their usual position in the large tent. The collection, needless to say, was in every way excellent, and included trained specimen plants, with numbers of well developed standards and some really effective pillar Roses. The foliage of all the plants was as fresh and bright as need be. The specimens included good examples of Spencer, La France, Madame Montet, Star of Waltham, Triomphe de Caen, Queen of Queens, Beauty of Waltham, Marie Baumann, Ulrich Brunner, and Mrs. J. Laing. The standards included Ella Gordon, Mrs. Sherman Crawford, Crimson Rambler, Modest, with grand flowers, Sylph and Enchantress. The Polyantha Claire Jacquier, placed alternately with Crimson Rambler, produced a good effect. The new Roses included Exquisite, Corallina and Tennyson all in good form; a capital front with twelve boxes of cut blooms made a good finish to the exhibit; a few baskets of cut Roses were also notable and effective.

Mr. B. R. Cant, Colchester, arranged a pretty exhibit of cut Roses, also some well-grown plants in 8-inch pots, which included Mrs. J. Laing, Ulrich Brunner, Baroness Rothschild, and Carolino Testout. The chief Roses in the boxes were The Bride, really grand; Mrs. J. Laing, Ulrich Brunner, Catherine Mermet, Prince Arthur, Merveille de Lyon, Madame S. Rhodocanachi, Madame Hoste, Maréchal Niel, glorious blooms; and Victor Hugo.

The pot Roses from Messrs. Frank Cant & Co., Braiswick Nurseries, Colchester, were chiefly of the decorative type, lightened with a few standards. Mrs. J. Laing, Madame de Watteville, Muriel Graham, Rainbow, Queen Mab, Bridesmaid, Fabia, Mrs. Paul, Maman Cochet, and Madame Hoste were good; also Mrs. Sandford, Marchioness of Londonderry, Lawrence Allan, Ards Rover, and a collection of Wichuriana Roses that will develop well during the show. The Polyanthas, Perle d'Or, Cecil Brunner, and Ma Paquette were also noteworthy.

Mr. W. Rumsey, Joyning's Nursery, Waltham Cross also contributed an effective exhibit of Roses in pots, with a front composed of boxes of cut blooms edged with Maidenhair Fern. The plants in pots were represented by Magna Charta, Mrs. J. Laing, Boule de Neige, Edouard Morren, Margaret Dickson, Comtesse de Serenye, Captain Hayward, and some fine specimens of Crimson Rambler. The boxes contained good Maréchal Niels, Niphotos, Souvenir d'un Ami, Dupuy Jamain, Margaret Dickson, and Mrs. Rumsey.

Plants and Flowers.

These are always one of the chief features at the Temple, and this year the display made by the different firms appear larger in spite of the fact that a greater variety of plants were exhibited than hitherto. Everyone was pleased to see less of that repetition that we have been accustomed to at this show, but here we had not only all the chief flowers blooming at this season, but the many new species and varieties on view were convincing that hardy flowers are as popular as ever. As to variety, well, we have the pretty little rock and alpine plants so tastefully arranged, and the gigantic Pæonies will serve as a contrast.

Mr. Charles Turner, Slough, arranged on either side of his Roses on the right, a few specimen Azaleas, such as Roi d'Hollande, Ceres, Grandis, Charmer, Duchesse A. de Nassau, and Marie Planchon; and on the left a few good specimen plants of Regal Pelargoniums, reminding visitors of bygone days. The best varieties are Edward Perkins, Joe, Rosetta, Empress of India, and Prince Leopold. A row of gigantic Malmaison Carnations formed a front not to be despised.

Messrs. J. Waterer & Sons, Ltd., Bagshot, had a large and varied group or bank of Rhododendrons in all their spring beauty, arranged

FIG. 117.—SPATHOGLOTTIS AUREO-VEILLARDII.

with a background of Acers in variety. The front was also finished with small Acers as graceful in appearance as Ferns, with *Ledum palustre*. The varieties included good plants of Sappho, Michael Waterer, Frederick Waterer, W. E. Gladstone, Pink Pearl in grand form, Cynthia, Francis B. Hayes, and John Waterer. The flowers were large, beautifully fresh and bright; a delightful exhibit.

Messrs. J. Peed & Son, Norwood, have been noted for their Temple displays of Caladiums, and this year again they have demonstrated the value of these ornamental foliage plants, and the exhibit was quite up to their usual style. The specimens were well coloured, and displayed with Maidenhair Ferns, while a few Palms at the rear lent grace to the exhibit. Fine specimens of John Peed, Lillie Burke, La Lorraine, Maria Mitana, Mrs. Harry Veitch, W. E. Gladstone, Princess of Teck, Lady Mosley, and Rio de Janeiro were noted amongst many others.

Messrs. J. Laing & Sons, Forest Hill, arranged a fine group of miscellaneous plants, in which Begonias, both single and double, formed the chief feature. Graceful Cocos and Caladiums were utilised with Ferns, Crotons, Nepenthes, and Orchids in variety, all in the best possible form. The best Begonias were Duke of Fife, a grand variety; Lady Tweedmouth, Mrs. Hall, Duchess of York, Duchess of Albany, Marchioness of Northampton, Miss Knollys, Saturn. The arrangement displayed the foliage plants well, as it did the Begonias also.

Messrs. Jas. Veitch & Sons, Ltd., Chelsea, contributed as exhibitors a large and varied display of plants. The Rhododendrons, Azaleas of the mollis and sinensis types were beautiful, and included Anthony Koster, Marshal Blucher, Alma Tadema, A. M. Koster, and Glory of Boskoop. Mount Pæonies were also gorgeous, the chief being Grand Duc de Baden, Regina Belgica, and Emilia. The quaint spikes of *Eremurus* in variety gave a curious effect. Standard Wistarias, Cytisus, Loniceras, and Laburnums were conspicuous, as was also a grand

branch of *Embothrium coccineum* with its scarlet flowers. *Philadelphus Lemoinei* Boule d'Argent (fig. 118, see page 436) arranged in baskets was also a feature; while the front contained *Hydrangeas stellata* fl.-pl. and *japonica tricolor* with numbers of small *Acers*, all beautifully coloured.

Mr. J. Jennings, gardener to L. de Rothschild, Esq., Ascott, had a semi-circular group of Carnations in pots that attracted the eye immediately on entering the tent. The well known form of Jim Smyth, with its bright scarlet flowers, formed the chief feature, while Sergeant George, Mrs. Streatfield, Sir C. Freemantle, Nell Gwynne, Miss A. Campbell, and Abigail assisted to make an effective group. The edging of Maidenhair Ferns and small Palms gave a desirable finish.

A truly magnificent display of plants was presented by Messrs. W. Cutbush & Son, Highgate, which was so extensive, and contained such a variety of plants, that it can be described as a flower show in itself. The plan of the exhibit was well executed, and the gigantic Palms that formed the background made a capital back to the exhibit, much more pleasing to look upon than the dirty canvas so apparent in many cases. The arrangement of the group left little to be desired practically speaking. The Malmaison Carnations formed the groundwork, from which graceful foliage and flowering plants formed miniature hillocks. The chief of the Carnations were Cecilia, a good yellow, Jane Seymour, Duke of York, Juliette, Lord Welby, a splendid red Malmaison, Adelina Patti, Wm. Robinson, Herbert J. Cutbush, a good petalled scarlet, and Princess of Wales. Groups of *Calla Elliottiana*, Moutan Pæonies, *Boronias*, and a ground edging of Ferns completed a grand exhibit.

Messrs. R. Smith & Co., Worcester, again delighted the visitors with a display of Clematises grown in pots all trained in balloon shape. The chief varieties were Lucie Lemoine, a well known double white, Lady Caroline Neville, Lord Neville, Princess of Wales, *Purpurea elegans*, a real picture; Fairy Queen, Excelsior and La France. The plants were all well flowered and developed. The same firm also arranged neatly a few well-flowered specimens of Crimson Rambler Rose. A delightful exhibit was seen in Messrs. J. Veitch & Sons'; Limited, Caladiums. The huge specimens were well grown, of beautiful colour, and the leaves in capital preservation. They were also arranged in such a manner that every specimen could be clearly seen, the leaves of some varieties being gigantic. Fine specimens of Louis A. Van Houtte, Gaspard Crayer, Baron A. de Rothschild, Duchesse de Mortemart, Rose Laing (grand), B. S. Williams, and the Marquis of Camden were to be seen amongst many others.

From Messrs. J. Jackman & Co., Woking, came a delightful display of Clematises and *Acers*. The plants included some very fine specimens, all remarkably clear and bright. The *Coccinea* hybrids were striking, and included Countess of Onslow, Duchess of York, Duchess of Albany, Admiration, Grace Darling, and the old *Coccinea*. Grand plants of Alba Magna, Fairy Queen, and Otto Froebel were conspicuous, as were also Lady C. Neville, Duchess of Edinboro', Henryi, and Mrs. Hope. The edging of *Spiræa* was effective. Messrs. Sutton and Sons, Reading, arranged a semi-circular group of herbaceous Calceolarias in the large tent, and right worthy were they of the position, for a better strain could not be desired. The plants were dwarf, and the blooms large and well spotted, while the variety in colouring leaves little to be desired.

Messrs. Kelway & Son, Langport, made a pleasing and interesting exhibit with their Pæonies and a few Pyrethrums. The Moutan varieties were especially fine. The chief were Lady Sarah Wilson, Lord Roberts, General French, General McDonald, and Lady Georgina Curzon, while the older forms were represented by Rudyard Kipling, Volunteer, Burne Jones, and Andrew Carnegie. Some of the herbaceous varieties were also on view and add to the effect.

The Home for Flowers of Messrs. H. Cannell & Sons, Swanley, does not belie its name, for the Cannas arranged appear to have come from a very delightful home, judging by the clean, smart appearance they produced; the spikes were large and the individual blooms bright and clean. The most striking varieties are Aug. Chautin, Duchess of York, Queen Charlotte, Pioneer, Menelik, Duke of Marlborough, Sec. Chabaune, Chicago, and Sister Dora. A small exhibit of double and single Begonias was composed of excellent plants, and included good blooms of Lady Bigge, Lady Churchill, Sir J. B. Maple, Mrs. Baden Powell, Admiral Dewey, Prince Henry, and Dr. Nansen. The same firm also contributed a good strain of herbaceous Calceolarias in fine variety, the plants were also of good habit; while a grand collection of Cacti containing some grand speci-

mens completed the display. Large plants of *Echinocactus Grusoni*, *Agave Victoria Regina*, *Cereus* in variety, *Opuntia ursinus*, were particularly noticeable.

Messrs. J. James & Son, Farnham Royal, staged a quantity of herbaceous Calceolarias, all fine plants, carrying a wealth of bright blossoms; for habit of plant, clear colouring and variety the strain will be hard to beat, and the general appearance of the plants was most satisfactory.

The Begonias of Messrs. T. S. Ware, Ltd., Feltham, created a furor last year, and the present exhibit was one that is likely to keep up the firm's reputation, not only as vendors of the tubers, but as growers of the plants also, for the collection was unique, the double varieties being especially good. The Duke of York, Mrs. Jas. Portbury, Miss Sylvia Morris, Lord Rosebery, Brilliant, Her Majesty, Mr. W. G. Valentine, Baden Powell, Lord Roberts, Captain Lambton, Lady Audrey Buller, Miss Jessie Pope, and Miss Else Engel were remarkably fine. Good single varieties were Novelty, Miss Nellie Thackery, Penracola, Mr. Harry Webb, Perfection, Majestic, Madame Belle Cole, and Miss Ada Jordan. The bank was quite a mass of gigantic flowers. The same firm also contributed a tasteful display of hardy flowers, with alpine and rock plants. The plants were effectively arranged and much admired. Pans of *Orchis fusca* with its quaint colouring, *Incarvillea Delavayi*, Iris Eggeri, *Primula Sieboldi*, *Cypripediums* in variety, and some Moutan Pæonies were most conspicuous.

Messrs. J. Laing & Sons, Forest Hill, occupied a table near the entrance of tent 3 with a variety of foliage and flowering plants. The *Streptocarpus* in variety were notable, while *Caladiums*, Palms, *Dracænas*, *Saxifragas*, and foliage Begonias made a fine display.

A magnificent display of hardy Azaleas came from Messrs. R. and G. Cuthbert, Southgate. The plants were well arranged, and the colours most pleasing. In the Mollis section the new Mrs. L. J. Endtz, a grand yellow, stood out clearly; as did Hugo Koster, Alphonse Levallee, Anthony Koster, President Carnot, and J. C. Van Thol. The Rustica hybrids were well represented, and included good plants of Apellus, Il Tirso, Aida, Mecene, and Norma. The exhibit was well arranged, every plant showing to its best purpose.

Messrs. Fisher, Son & Sibray, Ltd., Sheffield, occupied a good position in the centre of the tent with some beautiful foliage plants, which included good plants of *Aralia pulchra*, *A. Schufferi*, with some well-coloured Crotons and *Dracænas*. Bamboos gave the exhibit a light appearance, and some Cattleys, *Cypripediums*, *Odontoglossums* lent colour to the display, while a pretty groundwork was formed of dwarf foliage in variety. The front of the group was especially well arranged.

Messrs. Sander & Co., St. Albans, arranged a group of Azalea indica in the centre of the tent. The plants were decidedly formal in shape, but a perfect mass of brilliant flowers; they were an object lesson to those that require a list of Azaleas for next year's growing. The best varieties were Apollo, Donor, President Pfaff, Flora, Jean van Dyck (a bright scarlet), Princess Clementino, Schnee, Unica and General Portmeister Stephan, but all were really good and exhibited in first-rate style.

Messrs. J. Russell, Richmond, again demonstrated the value of Azalea hybrids, and on this occasion the A. Mollis were excellent, as were also the Ghent and Rustica varieties. In the former section Anthony Koster and Alphonse Lavellee were really good, while the hybrids were staged in a variety of colours. The edging of *Crocusma Baueriana variegata* was fairly effective.

In tent 3 Messrs. Barr & Sons, Covent Garden, had a remarkable display of hardy flowers and Tulips that occupied at least 100 feet. Not only was the exhibit large but extremely varied and well arranged. The little rock plants were tastefully arranged, and the specimens typical. The *Oxalis repens*, *Viola tricolor*, *Aubriotias*, and *Phlox atro-purpurea*, *Saxifraga pyramidalis*, Iris Susiana, *Gentiana verna* were all notable here, while arranged in stands were huge bunches of Pæonies, *Anemone pulsatilla*, *Lilium Harrisii* and *candidum*, with *Gladioli* Peach Blossom and Blushing Bride. A few late Daffodils reminded one of the closing season, while *Geums* *miniaturum*, *hybridum*, and *coccineum*, *Trollius napellifolius* and *japonicus* fl.-pl. shared the honours with bowls of Aneimones, a beautiful display of Spanish Irises, and Iceland Poppies. As showing the variety in the exhibit we next saw a collection of Japanese dwarfed trees, that were decidedly more curious than beautiful. Darwin Tulips were staged in grand variety, and included the well known forms of Loveliness, Rev. Ewbank, Glow, Maiden's Blush, Margaret, Joseph

Chamberlain, The Sultan, and May Queen, also a collection of cottage Tulips that were very pleasing. The species of *Tulipa* are also well represented, as are the Parrot and English Show varieties. These make a grand show in themselves, and contribute largely to the splendid exhibit.

A charming exhibit was that from Messrs. Backhouse & Son, Ltd., York. The rock and alpine plants were arranged as naturally as possible in miniature rockwork. The notable plants contained in this collection were *Androsace sarmentosa*, *Chumbyi*, *Saponaria ocymoides* alba, *Primula longiflora*, *Cistus purpureus*, a few Ferns, and a quantity of Sedums, Saxifragas, and similar plants were notable in a large variety of plants admirably arranged.

Gloxinias were staged by Mr. J. J. Upton, Irlam, Manchester. The exhibit was good, containing as it did a great variety in colour and marking. The plants were well grown and well flowered, while a few Maidenhair Ferns and *Caladium argyrites* gave a light appearance to the exhibit.

Mr. H. B. May, Dyson's Lane Nurseries, Edmonton, occupied both corners and a large space on the centre table with his exhibit, which was composed largely of Ferns, Zonal Pelargoniums, Coleuses. The Ferns comprised specimens of *Platycerium grande*, *Blechnum corcovadense undulatum*, *Nephrolepis pectinata*, and *Davallia decora*. Plants of *Clematis Nellie Moser*, Crimson Rambler Roses, *Statice profusa*, gave a little colour to the exhibit, while some good Coleuses, such as Mrs. Tolworthy, Victor, Golden Gem and Crimson Gem were conspicuous. A few well flowered Zonal Pelargoniums and Ivy-leaved Geraniums were also in good form. The Zonal Decorator is a grand variety, and the hybrid Achievement is also worthy of note.

Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell, again staged his collection of insectivorous plants, which attracted a dense crowd round the boxes all day, and made notetaking more than difficult. The Sarracenias included *Stevensi*, *Atkinsoni*, *crispata*, *Tolliana*, *Drummondii* alba and *Swaniana*, *Drosera dichotoma*, *Cephalotus follicularis*, *Dionaea muscipula*, and in fact the entire collection is well grown, and the plants the picture of health, certainly forming an interesting exhibit. Messrs. Young & Co., Stevenage, exhibited a collection of Cacti, also a few herbaceous plants, with Pansies and a few rock plants.

Messrs. Hugh Low & Co., staged a novel exhibit in a collection of *Schizanthuses*. The plants were a perfect mass of flowers, and several shades of colour were staged, demonstrating their value for decorative work. Messrs. J. Jackman & Sons, Woking, arranged a large exhibit of hardy flowers, which included some good *Aquilegia* hybrids. Geum in variety, Moutan Paeonies, *Edrianthus dalmaticus*, *Oenothera speciosa*, *Aster alpinus superbus*, *Primula japonica*, *Anemone sylvestris* fl.-pl., and *Trollius Orange Globe* were excellent amongst many other subjects, which it is impossible to enumerate.

A good display of herbaceous plants and Rhododendrons was staged by Messrs. Paul & Son, Cheshunt. The latter contained some bright hybrids from *R. Fortunei*. The Tulips were a feature, especially the Parrot varieties, and a few of the species. The Funkias also had good attractive foliage, while a collection of rock plants was tastefully arranged in boxes, and included many well-known plants suitable for the purpose.

It is doubtful if Messrs. Wallace & Co., Colchester, have ever staged a better display of Liliiums and rare hardy plants than those seen on this occasion. The collection of *Cypripediums* included beautiful plants of *spectabile*, *C. parviflorum*, *C. occidentale*, *calceolus*, *candidum*, and *pubescens*. The collection of Tulip species was a representative one, and included good specimens of most forms. Spanish Irises are staged in great variety, and a collection of Moutan Paeonies gave variety to the exhibit. A few choice *Calochortus* was admired, while *Lilium rubellum*, in fine form; *L. Thunbergianum* Orange Queen, *L. umbellatum grandiflorum*, *L. T. Van Houttei*, *L. u. erectum*, *L. Szovitzianum*, *L. longiflorum giganteum*, and *L. T. marmoratum aureum*, formed part of a choice collection grouped with Acers and Bambusas, and made a pleasing display.

Mr. J. Fleming, gardener to Sir Charles Pigott, Bart., Wexham Park, Slough, arranged an effective group of foliage and flowering plants of a decorative character. The arrangement was good and well executed. The flowering plants included splendid Malmaison Carnations, *Oncidiums*, *Dendrobiums*, *Ericas*, which included some fine plants of *E. Cavendishi*, *Boronias*, and *Lilium Harrisii*. The chief foliage plants were Crotons, Palms, Ferns, *Alocasias*, *Caladiums* and *Dracenas*. The groundwork and edging of Ferns, *Isolepis*, and tiny *Caladiums* was most effective.

Mr. Arthur Knowles, Horsell Birch Nursery, Woking, sent a basket of *Daphne cneorum* major, a pretty hardy shrub, well known and recently seen at previous meetings. The plants were well flowered. Messrs. Sutton & Sons, Reading, staged a large exhibit of *Nemesia strumosa* hybrids in variety; there is apparent improvement in the colours, of which there is now a wide range. The wind and rain had militated against the appearance of the plants, but no doubt they will improve during the show.

Calceolarias of the herbaceous type were staged by Messrs. Webb and Sons, Stourbridge, and a remarkably fine strain it is. The

FIG. 118.—PHILADELPHUS BOULE D'ARGENT. (See page 435).

colours are clean cut and bright, while the habit of the plants is decidedly dwarf. The enormous bank of bloom presented a fine appearance, and should do much to convince the public that the strain is one of the best extant. The edging of Ferns and Selaginellas all contributed to the beauty of the exhibit. The same firm also staged Gloxinias and Begonias that had been damaged in transit.

Mr. A. Perry, Winchmore Hill, had a grand display of hardy flowers, in which many new forms were to be seen; in fact the whole exhibit was most interesting, and included *Myosotis rupicola*, *Phlox The Bride*, *Oenothera speciosa rosea*, *Phlox G. F. Wilson*, *Primula japonica*, *Tulipa Picotee*, *Phlox canadensis* (fig. 119, page 438), *P. atro-purpurea*, Geums in variety, *Paeony tenuifolia*, *Incarvillea Delavayi*, *Aubrietia purpurea*, and *Ramondia pyrenaica*. These were all excellent, and a great many others might be classed in the same category. Mr. E. S. Towel, Hampton Hill, staged *Pelargonium Fire Dragon*, a semi-double form with narrow petals.

From Mr. H. J. Jones, Ryecroft Nursery, Lewisham, came a large exhibit of Tulips, Spanish Irises, Gladioli, and Begonias. The Tulips represented collections of cottage garden and Darwin varieties. Among the Darwins *Wilhelmina*, *Phyllis*, *May Queen*, and *Zephyr* were notable; *Tulipa Gesneriana strangulata*, a grand red variety, *T. flava*, *Ixias* in variety, and a few late Daffodils, which with *Spiræas*, and a variety of decorative plants, made a fine collection. There were also a few bunches of hardy flowers, with a good plant of H. J. Jones Carnation, a good dark crimson of the *Malmaison* section. Mrs. J. G. Day, a new Ivy-leaved *Pelargonium*, and a representative collection of single and double Begonias, in which the following varieties were good:—Mr. Harrison, Dick, *Admiration*, *Sensation*, *Exquisite*, H. J. Jones, Mrs. W. H. Webb, *Nero*, *Snowdrift*, and Mrs. J. B. Baxter. The plants were staged in *Panicum* and *Maidenhair* Ferns, and the arrangement proved most attractive.

Mr. Wm. Icton, Putney, always noted for his Palms and decorative plants, arranged a collection of foliage and flowering plants. In the former section the *Caladiums*, *Acers*, *Bambusas*, *Palms*, and *Ferns* were to the fore, while the flowering plants were represented by *Lilium Harrisii*, *Erica Cavendishi*, *Boronias*, *Spiræas*, and *Lily of the Valley*. The whole arrangement was carefully carried out, and presented a pleasing appearance.

Lily of the Valley was arranged by Mr. J. Jannock, Dersingham, Sandringham, in Royal style with a few large vases of single and double Lilacs. The "Fortins" variety of Lilies was shown in good form, while the Lilacs included *Charles X.*, *Madame Abel Chatenay*, *Madame Lemoine*, double white; *Marie Legrange*, and *Président Grevy*. An artistic effect was produced by sprays of *Asparagus*.

From Messrs. J. Peed & Sons, Norwood, came a pretty and varied collection of *Gloxinias*; the plants were well developed, and the flowers fresh and bright; selfs and spotted flowers were equally represented, and the strain is undoubtedly a good one. The whole formed a most attractive exhibit. The Guildford Hardy Plant Co., Guildford, had a most interesting and beautiful display of rock and alpine plants, also a collection of *Conifers* arranged behind in the way of a miniature forest. *Geums* were there in variety, hardy *Cypripediums*, *Primula japonica splendens*, *Violas* in variety, *Houstonias* full of bloom, pretty *Phloxes*, *Gentianas*, *Oxalis*, and *Trollius europæus*. Judging from the crowd in front of this exhibit it was highly appreciated.

Mr. M. Prichard, Christchurch, Hants, is well known as an exhibitor of hardy plants, and on this occasion made not only a large display, but also an interesting one. The blooms of *Iris Susiana*, *Tulipa Picotee*, *Centaurea montana*, *Spiræa reticulata*, *Pyrethrums* in variety, *Campanula dahurica* with its deep violet colour, *Geum miniatum*, *Trollius multiflorus* and *asiaticus*, *Oxalis enneaphylla*, and *Cytisus purpureus incarnatus*, amongst others, helped to make up this splendid display.

Messrs. W. Paul & Son, Waltham Cross, had a number of boxes containing a good collection of Lilacs, *Rhododendrons*, and other hardy plants. The Lilacs were particularly fine, *Madame Lemoine*, *Madame Cassimer Perrier*, *La Tour d'Anvergne*, and *Géant des Batailles* being amongst the best. From Messrs. I. House & Son, Westbury-on-Trym, Bristol, came a collection of *Fancy Pansies* and *Violas*, all growing in pots, not perhaps the best method of showing them for effect. The best *Violas* were *Amy Barr*, *Lady Reah*, *Argosy*, *Golden Fleece*, *Ruth*, *Border Witch*, *Kitty Belle*, and Mrs. R. K. Mitchell, also some glasses of *Viola cucullata*, a variety with long stems, said to be useful for growing under trees.

On a huge centre table Messrs. J. Veitch & Sons, Ltd., arranged a magnificent exhibit of *Streptocarpus*, containing hundreds of plants in a great variety of colours. The individual plants were all well flowered. Then there was a wonderful collection of *Phyllocactus* in a great variety of colours, with a group of hybrid *Aquilegias* in pots. The strain is undoubtedly a good one, for the colours of the flowers are most delicate. The *Phyllocacti* included *Ena*, a rosy red variety; *Adonis*, a rosy pink form; *Epirus*, *Admiration*, *La Reine*, *Jessica*, a delicate pink; *Exquisite*, *Romeo*, crimson edged purple; *Brilliant*, a bright crimson; *La Belle*, a creamy white; *Cooperi*, white, and *Nemesis*, a grand pink. The *Streptocarpus* hybrids were to be seen in many colours, the variety *S. achimeniflorus giganteus* and *S. a. alba* being especially fine and free flowering.

Ireland was to the fore with a grand display of Tulips sent by Messrs. Hogg & Robertson, Mary Street, Dublin. The Darwin varieties had suffered somewhat from the weather, but the cottage varieties and *Tulipa* species were well grown, and a capital display was the result. The collection of *Cacti* from Mrs. Bodkin formed a pleasing change to

the glare of neighbouring exhibits and was much appreciated, a few *Epiphyllums* and *Phyllocacti* were in flower, and the rest of the curiosities seem to be well cared for. Messrs. R. Smith & Co., Worcester, arranged a large bank of hardy flowers in which the following were noted:—*Heuchera sanguinea*, *Phlox canadense*, *Adonis pyrenaica*, *Lupinus nootkatensis*, *Irises* in variety, *Montan Pæonies*, *Geums* in large variety, *Trollius caucasicus* and fine Tulips; a well displayed exhibit.

From the Midlands we had a beautiful collection of *Violas* staged by Mr. W. Sydenham, Tamworth. The sprays were arranged with *Maidenhair*, and the following were the best forms:—*Mary Scott*, *Kitty Bell*, *Niphetos*, *Amy Barr*, *Hawk*, *Primrose League*, and Mr. A. D. Parker. Mr. W. J. Godfrey, Exmouth, made a pleasing display of *Emanuel Lias*, a decorative *Pelargonium*, very free flowering, and the habit of the plant is also good.

From Messrs. J. Cheal & Sons, Crawley, came a small collection of *Violas*, which included good sprays of *Melampus*, *Hamish*, *Sydney*, *Duchess of Sutherland*, *J. B. Riding*, *Countess of Kintore*, and *Border Witch*; also a collection of hardy flowering shrubs, which included large bunches of *Exochorda grandiflora*, *Viburnum Lantana*, *Prunus* in variety; also a pretty rockwork arrangement, tastefully planted with *Phlox G. F. Wilson*, *P. frondosa*, *P. Vivid*, and *The Bride*; *Viola bicolor*, *Gentiana acaulis*, and a variety of *Sedums* and *Saxifragas* in quantity. Mr. H. Walters, gardener to Lord Gerrard, Eastwell Park, Ashford, exhibited a group of *Carnations*, a pale straw colour named *Lady Gerrard*, a variety that has evidently some *Malmaison* blood in it.

A collection of *Sweet Peas* was staged by Messrs. Dobbie & Co., Rothesay, which included all the well known forms. The vases were well arranged, but the flowers had evidently opened under a little too much persuasion; also *African* and *French Marigolds* in pots. From Mr. S. Bide came a basket of *Callas* named *Primrose League*, a pale form of *C. Elliotiana*; the pale lemon colour will be attractive.

Messrs. Carter & Co., High Holborn, occupied the entire centre of one tent with their exhibit, which was comprised chiefly of *Cineraria stellata* in good variety; *Empress Petunias*, a single strain of excellent quality; double *Petunias*, a choice strain of beautiful double flowers; herbaceous *Calceolarias*, a well spotted strain, excellent in size and of good habit; a well-arranged rock garden, beautifully stocked with a variety of plants, while a trophy of *Lily of the Valley* in the centre made an imposing exhibit.

Fruits and Vegetables.

In estimating the merits of the vegetables that are contributed to this portion of the show, it is essential that the season through which we are at present passing be taken into consideration. We have to bear in mind that it has, generally speaking, been decidedly unfavourable to all vegetation, and naturally this applies with great force to kitchen garden crops. Having this in view we think everyone will be agreed that the products shown were most meritorious and reflect the utmost credit upon the producers. Fruit again was really splendid, and the trees in pots were a constant source of surprise and delight to the thousands of interested spectators. Some of these were critical in their remarks, but there was little to cavil at, as the untoward weather, though it may not affect indoor as much as outdoor crops, is undoubtedly prejudicial to the perfect development of all kinds of fruit, not excepting those grown under glass.

There was one feature of the Temple Show which would be missed, perhaps, more than any other, and that is the collection of fruit trees in pots from Messrs. T. Rivers & Son, Sawbridgeworth. They annually occupy a position in the large marquee, and the more frequently they are seen the more they are appreciated by the spectators. The trees are invariably characterised by clean, stout growth with no suspicion of over-luxuriance, and substantial healthy leaves. The only variety represented on this occasion was *Cardinal Nectarine*, which is now so widely known and appreciated.

Visitors this year had a treat that is not annually vouchsafed to them, and this was found in the exhibit of fruit trees in pots from Mr. J. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton. Few, if any, gardeners have done more than Mr. Hudson in endeavouring to popularise this phase of fruit culture, and the trees exhibited proved how able is he to teach others in what way they should go to insure the most satisfactory results. There were magnificent *Peaches*, *Nectarines*, *Plums*, *Cherries*, and *Grapes*, with examples of the fruit in boxes in the foreground. The *Cherries*

comprised Bigarreau de Schrecken, Governor Wood, Frogmore, Early Bigarreau, and Empress Eugénie. Early Prolific Plum was very fine, as were Cardinal Nectarine and Amsden June Peach. Mr. J. Hudson sent also a box of handsome Royal Sovereign Strawberry.

The reputation that has been gained by Messrs. Sutton & Sons, Reading, for the excellence of their strains of Marrowfat Peas, that any exhibit of these from this source is sure to be hailed with pleasure. The early varieties of Marrowfat Peas have the immense advantage of being ready for use before the hard, round seeded sorts, while of course possessing the much superior Marrowfat flavour. There were two varieties represented in large mounds—namely, Early Giant and Bountiful. The pods were magnificent.

Mr. S. Mortimer, Rowledge, Farnham, is a regular attendant at the Temple Show, and his exhibits are invariably worthy of close inspection. On this occasion he had eight boxes of Cucumbers, containing handsome examples of Marvel, Sutton's A1, Sutton's Peerless, Tender and True, Telegraph, and Lockie's Perfection. They were quite a treat to see after the feast of flowers.

As a grower of choice fruit, Mr. J. McIndoe, gardener to Sir Joseph Pease, Bart., M.P., is well known, and the collection from Hutton Hall was particularly meritorious. The Grapes included Black Hamburg, Foster's Seedling, and Early Summer Frontignan; a shapely Pine; Royal Sovereign Strawberry; Hutton Hall, Scarlet Premier, Best of All, and Yorkshire Beauty Melons; Downton, Bigarreau Napoleon, May Duke, and Black Tartarian Cherries; The Czar Plum, Brown Turkey Figs, Early Rivers and Précoce de Croncels Nectarines, with Apples and Tomatoes were shown.

A small group of Nectarines and Peaches in baskets was shown by Messrs. T. Rivers & Son, in addition to the pot trees. The Peaches included the Duke of York (Early Rivers Nectarine and Alexander Peach), Duchess of York (Nectarine Early Rivers and Early Rivers Peach), and Prince Edward (Early Rivers Nectarine and Hale's Early Peach); gathering of Duchess of York commenced on May 1st. The Nectarine was Cardinal, in superb form.

Mr. W. Godfrey, Colchester, was represented by a number of bunches of Asparagus; the heads were simply immense. Mr. A. J. Harwood, another Colchester grower, contributed similar produce.

A miscellaneous group of fruits and vegetables was contributed by Mr. W. L. Bastin, gardener to Alexander Henderson, Esq., M.P., Buscot Park, Faringdon. The only vegetables were Asparagus, French Beans, Cauliflowers, Cucumbers, and Tomatoes. Of fruits we observed Melons, Apples, Strawberries, Peaches, Nectarines, Figs, and Cherries.

A meritorious exhibit was that from Mr. W. Fife, gardener to Lord Wantage, V.C., Lockinge Park, Wantage, which was arranged in a perfectly unique manner. Each dish of fruit was surrounded by beautiful blooms of Fortune's Yellow Rose, the peculiar colour of which in some instances detracted from the appearance of the fruit. Amongst other dishes were Buckland Sweetwater, Madresfield Court, Foster's Seedling and Black Hamburg Grapes; Hero of Lockinge and British Queen Melons; Adam's Pearmain, Winter Queening and King of Tompkins County Apples, with Royal Sovereign Strawberries, Empress Eugénie Cherries, White Marseilles Fig, Monstera deliciosa, Citrons, Tomatoes and Oranges.

Apples from Messrs. G. Bunyard & Co., Maidstone, may be taken to mean most excellent Apples. The fruits have size as well as firmness and colour, and it is a matter for regret that smaller growers cannot keep them so long. The most conspicuous dishes were Nelson Codlin, Cornish Aromatic, Tibbit's Pearmain, Mother, Newton Wonder, Sanspareil, Tyler's Kernel, New Hawthornden, Hoary Morning, Grange's Pearmain, Rosemary Russet, Gloria Mundi, Beauty of Kent, Bramley Seedling, Lord Derby, Smart's Prince Arthur, Cox's Orange Pippin, Annie Elizabeth, Striped Beefing, Bismarck, Betty Geeson, Wellington, King's Acre Pippin, and Baxter's Pearmain.

Messrs. J. Watkins & Co., Withington, Hereford, also contributed Apples to the general display, and the richness of colour that is taken on in that favoured county made them look very handsome. The several fruits were firm and solid, and included Claygate Pearmain, New Bess Pool, Northern Spy, Gooseberry, Wadhurst Pippin, Hoary Morning, Baxter's Pearmain, Rymer, Aromatic Russet, Court. Pendu Plât, Blenheim Orange, Royal Russet, Winter Peach, Sturmer Pippin, Calville Malingre, Graham, Beauty of Kent, Norfolk Beefing, and Duke of Devonshire.

Fragrance and utility were the characteristics of the exhibit from Messrs. W. Poupart & Sons, Marsh Farm, Twickenham, for the firm howed Lilies of the Valley and Rhubarb. The latter was superb, and

included Linnæus, Victoria, Champagne. The Lilies were delightfully sweet and represented the variety Victoria from the open air.

The whole of the central table in the small tent was occupied by Messrs. J. Carter & Co., High Holborn, with a varied and beautiful assortment of flowers and vegetables. The former are referred to in another paragraph, and we shall therefore only note the latter at this point. The product included Carter's Telephone, Daisy, and Early Morn Peas, Holborn Masterpiece Bean, Earliest of all Cucumber, First Crop Potato, Duke of York Tomato, Blenheim Orange Melon, Early Forcing Turnip, White Advancer Bean, and Royal Osborne Cucumber.

Certificates and Awards of Merit.

Begonia Thos. Hall (J. Laing & Sons).—A magnificent double variety. The colour is soft salmon in the outer portion and blush within (award of merit).

Begonia Lord Roberts (T. S. Ware, Ltd.).—A superb double variety. The basal colour is white with a broad scarlet margin (award of merit).

FIG. 119.—PHLOX CANADENSIS (DIVARICATA). See page 436.

Begonia Mr. W. G. Valentine (T. S. Ware, Ltd.).—A double scarlet variety; the petals are of exceptional breadth (award of merit).

Bougainvillea Maud Chettleburgh (J. Chettleburgh).—A superb form; the colour is crimson lake (award of merit).

Carnation H. J. Cutbush (W. Cutbush & Son).—This is one of the finest scarlet varieties that have been shown of late. The flower is of the first size, and of splendid substance (award of merit).

Cattleya Mossiæ Ronseleana (de Wavrin).—A handsome variety. The sepals and petals are exceptionally rich rose, and the fimbriated lip is velvety crimson purple with deep yellow on the side lobes (award of merit).

Cattleya Mossiæ Our Queen (F. Sander & Co.).—An almost white variety with faint rose in the sepals and petals. The lip has a broad white fimbriated margin, with central crimson markings and yellow side lobes (award of merit).

Cattleya Mossiæ Wagneri Hassall's var. (Stanley Ashton & Co.).—A chastely beautiful variety that is pure white save for the yellow side lobes (award of merit).

Cymbidium P'Ansoni (H. Low & Co.).—This is said to be a natural hybrid. The sepals and petals are pale green with reddish bars, more pronounced at the base. The lip is milk white with a brown tinge on the front portion (award of merit).

Cypripedium Mary Beatrice (Charlesworth & Co. and G. W. Law Schofield).—This is said to be a hybrid from *C. bellatulum* and *C. Gowerianum magnificum*. It is intensely dark. The large dorsal sepal is deep claret with dark lines. The petals are claret with black spots and the pouch claret (award of merit).

Edrinthus dalmaticus (G. Jackman & Son).—A charming semi-prostrate growing plant producing a profusion of pale blue flowers (award of merit).

Gloxinia Strain (J. J. Upton).—A strain of decided merit. The flowers have refined appearance with form and good colour (award of merit).

Melon Buscot Park Hero (W. L. Bastin).—This is from a cross between Hero of Lockinge and Imperial Green Flesh. It is a handsomely netted fruit of good flavour, and with green flesh (award of merit).

Lælio-Cattleya callistoglossa excelsa (F. Sander & Co.).—This is the finest variety of this grand Orchid that has yet been shown, and was one of the most striking Orchids in the show (first-class certificate).

Lælia purpurata Littleiana (H. Little).—A perfect purpurata. The sepals and petals are pure white, as is the front portion of the lip. The outer side lobes are crimson, and the throat yellow veined crimson (first-class certificate).

Lælio-Cattleya G. S. Ball (J. Veitch & Sons).—This bigener is from *Lælia cinnabarina* and *Cattleya Schröderæ*. The colour is intense orange (award of merit).

Lælio-Cattleya Massangeana (A. A. Peeters).—This is from a cross between *Lælia tenebrōsa* and *Cattleya Schilleriana*. The sepals and petals are brownish red with green at the base. The lip is deep crimson (award of merit).

Lælio-Cattleya Hérode (A. A. Peeters).—This is from *Cattleya O'Brieniana* and *Lælio-Cattleya elegans Turneri*. The recurving sepals and petals are deep rose. The front of the lip is crimson, and the central portion canary yellow; the throat is crimson (award of merit).

Lilium Thunbergianum Orange Queen (R. Wallace & Co.).—A grand Lilium of which the varietal name accurately describes the colour (award of merit).

Lycaste Ballæ (Charlesworth & Co.).—A superb flower. The sepals are dull maroon; the petals are brighter and the lip is white almost obscured by crimson spots (award of merit).

Odontoglossum Rolfeanum Optimum (Ch. Vuylsteke).—A beautiful variety. The colour is white with large and small chocolate spots and blotches. The front portion of the lip is pure white (first-class certificate).

Odontoglossum Rolfeanum ardentissimum (Ch. Vuylsteke).—This much resembles the preceding, but the colour markings are purple (award of merit).

Odontoglossum Souvenir de Victor Hye Lebrun (J. Hye Laysen).—This is from a cross between *O. Harryanum* and *O. luteo-purpureum*. Probably the finest Orchid in the show. The sepals and petals are almost wholly brown, the yellowish green only showing occasionally. The front of the lip is pure white and the basal portion crimson (first-class certificate).

Odontoglossum Victoria Regina (A. A. Peeters).—A small, somewhat starry flower. The colour is white with brown spots and blotches (award of merit).

Odontoglossum Mrs. F. Peeters (A. A. Peeters).—A fine crispum. The white is almost wholly obscured by the brown and rose markings (award of merit).

Odontoglossum crispum Arthur Ashworth (E. Ashworth).—A superb form, though the flower is small. The colour is delicate cream with very large crimson brown spots and blotches (first-class certificate).

Odontoglossum crispum Ernest Ashworth (E. Ashworth).—This is small, but of perfect form. The basal colour is almost obscured by chocolate (first-class certificate).

Odontoglossum crispum Confetti (L. Linden).—This is a singularly beautiful spotted form. The ground is pure white and the spotting reddish chocolate (award of merit).

Odontoglossum crispum radiosum (L. Linden).—A small but handsomely shaped variety. The colour is white clouded with rose in the sepals, and having large reddish-brown blotches (award of merit).

Oenothera speciosa rosea (A. Perry).—This is a dwarf-growing plant that produces numbers of pale rose coloured flowers (award of merit).

Pæony Lady Sarah Wilson (Kelway & Son).—A variety of the tree section. The immense flower is soft rose (award of merit).

Pelargonium Mrs. J. G. Day (H. J. Jones).—An Ivy-leaved variety, with very large crimson scarlet flowers borne in fine trusses (award of merit).

Schizanthus Strain (H. Low & Co.).—A charming strain of compact habit, and very free flowering; the colours generally are light (award of merit).

Tulipa galatica (Van Tubergen).—A yellow coloured species with pointed petals (award of merit).

Tulip Mrs. Moon (Barr & Sons).—A superb cottage Tulip, with rich yellow flowers (award of merit).

Tulip Mabel (Barr & Sons).—A deep rose coloured breeder Tulip of splendid form and substance (award of merit).

Medals and Cups Awarded.

The order in which the names are entered under the several medals and cups has no reference whatever to merit, but is purely accidental.

Gold Medals.—To Sir F. Wigan, Bart., Mortlake (gardener, Mr. W. H. Young), for Orchids; Messrs. F. Sander & Co., St. Albans, for Orchids, Azaleas, &c.; Messrs. J. Veitch & Sons, Chelsea, for Caladiums, Cacti, flowering shrubs, &c.; Leopold de Rothschild, Esq., Gunnersbury House, Acton (gardener, Mr. J. Hudson, V.M.H.), for fruit trees and Water Lilies; Lord Wantage, Lockinge Park, Wantage, for fruit.

Silver Cups.—Messrs. J. Cypher, Cheltenham, for Orchids; Mons. Lucien Linden, Brussels, Orchids; Messrs. Charlesworth & Co., Bradford, Orchids; Mr. Chas. Turner, Slough, Roses, Pelargoniums, Carnations; Messrs. J. Carter & Co., Holborn, vegetables, Calceolarias, &c.; Messrs. Barr & Sons, Covent Garden, Tulips, herbaceous plants, &c.; Messrs. W. Cutbush & Sons, Highgate, topiary work, &c.; Messrs. Fisher, Son & Sibray, Sheffield, stove and miscellaneous plants; Messrs. Hugh Low & Co., Enfield, N., Orchids and new plants; Messrs. Paul and Son, Cheshunt, Roses, cut flowers, and Bamboos; Sir Chas. Pigott, Bart., Slough, Palms and Crotons; Messrs. R. Smith and Co., Worcester, Clematis and Roses; Messrs. J. Peed & Son, Norwood, S.E., Caladiums, Gloxinias, &c.; Messrs. W. & J. Birkenhead, Sale, Ferns; Messrs. J. Hill & Sons, Edmonton, Ferns; Sir J. Pease, Bart., M.P., Guisborough, fruit; Messrs. T. Rivers & Son, Sawbridgeworth, fruit trees; Messrs. G. Bunyard & Co., Maidstone, fruit; Messrs. W. Paul and Son, Waltham Cross, Roses and Rhododendrons; Mr. T. S. Ware, Ltd., Feltham, Begonias, herbaceous plants; Messrs. H. Cannell and Son, Swanley, Cacti, Cannas, plants, &c.

Silver-gilt Flora Medals.—To Messrs. Stanley Ashton & Co., Southgate, for Orchids; W. A. Gillett, Esq., Orchids; Mr. H. J. Jones, Lewisham, Begonias and cut flowers; Mr. W. Rumsey, Waltham Cross, Roses; Mr. Amos Perry, Winchmore Hill, hardy perennials; Messrs. G. Jackman & Son, Woking, Clematis and hardy perennials; Mr. B. R. Cant, Colchester, Roses; Messrs. R. & G. Cuthbert, Southgate, Azaleas; Mr. M. Prichard, herbaceous plants; the Guildford Hardy Plant Nursery, Guildford, alpine; Mr. H. B. May, Edmonton, foliage plants and Roses; Messrs. J. Waterer & Sons, Bagshot, Rhododendrons; R. I. Measures, Esq. (gardener H. J. Chapman), insectivorous plants; the Duke of Northumberland, Nepenthes; Messrs. J. Cheal & Sons, Cacti, &c.; Messrs. Wallace, hardy plants and Lilies; Messrs. Kelway, Pæonies, &c.; Messrs. Sutton, Calceolarias; Mr. J. Russell, trees and shrubs; Mr. J. Watkins, Apples; Leopold de Rothschild, Esq., Ascott, Leighton Buzzard (gardener Mr. J. Jennings), Carnations.

Silver-gilt Knightian Medal.—To A. Henderson, Esq., M.P., for fruit and vegetables.

Silver Flora Medals.—To Mr. W. Iceton, for decorative plants; Messrs. Laing, Maples and stove plants; Mr. T. Jannock, Lilies of the Valley; Mr. W. Poupart, Lilies of the Valley; Messrs. Cripps, Maples; Mr. R. Green, Crotons; Messrs. B. S. Williams, Orchids; Ludwig Mond, Esq., Orchids; Mr. G. W. Piper, Roses; Messrs. F. Cant & Co., Roses; Messrs. Hogg & Robertson, Tulips; Messrs. W. H. Rogers, Rhododendrons; Messrs. J. James & Son, Cinerarias; Messrs. Webb & Son, for Begonias, Gloxinias; Lord Gerard, Carnations; Messrs. Backhouse, Orchids, Alpines, &c.; Messrs. Fromow, Maples.

Silver Knightian Medals.—To Mr. S. Mortimer, for Cucumbers; Mr. W. Godfrey, Asparagus; Mr. Harwood, Asparagus.

Silver Banksian Medals.—To Marquis de Wavrin, for Orchids; Messrs. Dobbie, Sweet Peas; Mrs. Bodkin, Cacti; Messrs. Young, Cacti; The Misses Hopkins, herbaceous plants; Mr. P. Erseleus, Petunias; Messrs. Wavren, Astilbes.

It is our pleasing duty in drawing this report to a close to testify once again to the excellence of the arrangements. In an exhibition of such magnitude as this the work entailed is enormous, and the managers may rest content in the knowledge that their admirably carried out duties have met with general approbation. Everyone should be grateful to the Rev. W. Wilks and Messrs. Frank Reader, S. T. Wright, and T. Humphreys for their unfailing courtesy and anxiety to afford information on such a peculiarly trying occasion as this.

Orchids at Hollycombe.

SOME of the most profusely flowered specimens of *Dendrobium nobile* and its variety *Wallichianum* I have had the pleasure of seeing are in the possession of J. C. Hawkshaw, Esq., Hollycombe, Liphook. The entire collection is not extensive, the majority of the plants being accommodated in one house, erected especially for them a few years ago; but the rude state of health and the luxuriant growth of several of the different species contained therein, amply demonstrated the pleasure which can be obtained in a mixed collection cultivated in one structure.

The *Dendrobiums* were, however, at the time of my visit arranged in the form of a bank in the spacious conservatory adjoining the mansion. There was a Palm in the background set in a groundwork of *Adiantum cuneatum*, while here and there small plants of *Cocos Weddelliana* were judiciously interspersed, and added greatly to the effect. One specimen was superb, and a credit to Mr. Silcock the courteous gardener and grower of these *Dendrobiums*; it measured 4 feet in diameter, while closely studded on the several dozen well-matured pseudo-bulbs were upwards of 1100 blooms. In close proximity was another example with fully 1000 flowers; the latter was growing in a 10-inch pot; several others were carrying hundreds of fully expanded blossoms.

These specimens I learnt were young offsets made up in their present flowering receptacles three seasons ago. These, in the opinion of Mr. Silcock, considerably outdistance plants made up and repotted in the usual way. It is essential to exercise great care in watering until the offsets are established; afterwards they are kept at the warmer end of the house and are accorded tropical treatment in the form of copious supplies of water both at the root and in the atmosphere. Occasionally during the season they are given a little weak liquid manure, made from fowl manure, alternated with soot water, in order to stimulate the growth. As the growths mature the plants are removed to cooler quarters, every care being taken to insure the thorough ripening of the pseudo-bulbs, as on this depends satisfactory flowering. By attending to a rotation of plants, Mr. Silcock experiences no difficulty in maintaining a succession of well bloomed plants from January until June, those for the former period being afforded a very slight rest prior to restarting, while others are retarded and brought forward as required.

In the same house were well-grown specimens of *Oncidium sphacelatum grandiflorum*, with some two dozen lengthy spikes of pretty chocolate and yellow blossoms; a well-flowered plant in a basket of *Odontoglossum citrosum*; the somewhat rare *Cattleya dolosa*, *Cypripedium villosum*, *C. Sedeni*, and *C. Lawrenceanum*. *Laelia superbiens*, which is rather difficult with some growers to grow into fine plants, was in good condition at Hollycombe, having carried a dozen spikes 5 feet in length with from twelve to twenty blossoms on the summit of each. *Dendrobiums densiflorum*, *thyrsoflorum*, *Pierardi*, *chrysanthum*, and *moschatum* were luxuriating, while the common *Epidendrum evectum* also occupied a place. These are a few of the Orchids that were particularly noted on the occasion of my visit, though several other species find a congenial home in this structure.

Of the numerous other glass houses it is not my purpose to speak at this moment; suffice it to say the occupants of each fully justified the care and skill bestowed on them. Mention must, however, be made of the fine specimen of *Camellia alba-plena*, planted out in a cool house. Though of a great age—i.e., one hundred years—it was moved from the conservatory some eight years by Mr. Silcock, and replanted in its present quarters; it annually produces some thousands of its chaste blossoms from November to April. Equally at home is another tree of the same variety, planted out of doors in a southerly position. The choice specimens of *Coniferae*, flowering shrubs, *Rhododendrons*, *Azaleas ponticum* and *mollis* I must pass with a word, much as they deserve extended mention.—GEO. HAGON.

At Chelsea.

ONE of the facts in connection with the Temple Show that is regretted yearly is that Messrs. J. Veitch & Sons, Ltd., do not exhibit from their unrivalled collections of Orchids at Chelsea, Langley, and Feltham. But so it is. Their exhibit is made up at the Royal Exotic Nursery at Chelsea, and what the visitor to the Temple Show

loses the visitor to the King's Road establishment gains. Everyone who goes to Chelsea at any time expects to find at least a few Orchids in flower, and no one need fear disappointment; it is, however, just at this time that each house becomes more than ordinarily beautiful, for on each hand there are flowers of every conceivable size, form, and colour. Let those, therefore, who can find the time make tracks for Chelsea to see Orchids in a dozen houses, and find how well these plants may be made to thrive even in this unfavourable part of our smoky metropolis. All those in flower are not grown there of course, but the majority are, and that is sufficient to show the capabilities of the grower, Mr. Harris, the plants and the climate.

For very many years the first Orchid house running at right angles to the long walk has been filled with *Odontoglossums*, particularly crispums; but here, as elsewhere, "the old order changeth," and the principal portion of the collection is now conspicuous by its absence. The plants have been transferred to Feltham, hence the firm has now Orchids there, as well as at Chelsea and Langley. In place of the *Odontoglossums* we find *Cattleyas* and *Laelio-Cattleyas* in excellent variety and abundant quantity. There are large numbers of *Cattleya Schröderæ* just passing their best, but still remaining sufficiently fresh to prove the presence of more than a few varieties of exceptional quality. *C. Philo* is a hybrid from *C. Mossiæ*, and *C. tricolor* and varies in colour from soft blush to deep rose-purple. *Laelia latona* is really superb in its brilliant colours, as indeed are the bright yellow *Laelio-Cattleya Zephyra*, with its crimson lip; *L.-C. Wellsiana albida*; *L.-C. Hyeana*, particularly rich; and *L.-C. Daphne*, which was obtained from *Cattleya Mossiæ* and *Laelia elegans*.

In the structure running parallel with the main walk are some splendid plants of *Oncidium concolor*, which have made a wonderfully attractive display during the past few weeks. This is indeed a charming Orchid when seen in such numbers. *O. Marshallianum*, too, with its great spikes, is in fine form, and lends good aid in adorning the house. Of *Odontoglossums* noted one form of triumphans is particularly good, while several other varieties are little inferior. *O. Halli* is admirably represented, as also is *O. vexillarium*, with the pleasing *O. cirrhosum*. These, with many others, make this house one of the most beautiful in the whole series.

Continuing our tour, we quickly find ourselves amongst the *Dendrobiums* in baskets hanging from the roof, with *Cypripediums* on the side stages, while still further along are numbers of *Phalænopsis*, many of which are in flower. The *Dendrobiums* are not confined to one house, but are comparatively numerous in several. Amongst the most conspicuous are the chastely beautiful *Bensoniæ*, *Alcippe*, and *Euterpe*, with the much showier though not more beautiful *thyrsoflorum* and *chrysotoxum* in the Orchid rockery. *Burlingtonia pubescens*, with its paper white, sweetly perfumed flowers, is worthy of all the admiration that it receives from the many visitors. Several of the *Phalænopsis* are peculiarly pretty, as will be seen from the names of *John Seden* and *Hermione* (a hybrid from *P. Stuartiana* and *P. Luddemanniana*), as well as *P. Manni* and *P. Luddemanniana*, which in colouring are perhaps more quaint than beautiful. *Spathoglottis aureo-Veillardii* and *Zygocolax Veitchii* are pictures that always attract as well for their distinctive form as for their beauty.

The most striking *Cypripedium* is *Lawrenceanum*, whose handsome flowers stand boldly above the equally handsome leaves. Of chaster beauty is *C. niveum*, with its milk white delicate looking flowers. Of the others observed the best were *Fraseri*, *Euryalæ*, *Mastersianum*, *Joseph Chamberlaini*, *callosum*, *ciliolare*, and *Ædon*. Returning to the Orchid rockery we find *Bifrenaria Harrisonæ*, *Epidendrum langleyense*, whose yellow flowers last in good condition for quite two months, *Cymbidiums Lowianum* and *eburneum*, with *Cypripedium Rothschildianum*, and *Oncidiums pulchellum*, *sarcodes*, *ampliatum*, *pulvinatum*, and *divaricatum*. The two latter are very similar in the form of the branching spikes, but the first named produces its paler coloured flowers somewhat later than *O. divaricatum*.

It would be no easy task to say how many persons have seen and admired the great *Cattleya* house, which is usually at the present period of the year the home of hundreds of flowers. This season, however, has been very unfavourable to the development of the blooms, and as a consequence the most beautiful moment of the display will be some two or three weeks later than the average. There are the grand plants with considerable numbers of flowers, every one of which is worthy of close examination. The time and opportunity for particularisation are, however, not now, and we must content ourselves with the bare announcement that *Cattleyas Mendeli*, *Lawrenceana*, *citrina* are splendid, and that *C. Mossiæ* is somewhat later. *Laelia purpurata*, which is generally superb, is represented by a few excellent flowers, both light and dark in hue, and hundreds of sheaths which will probably produce many flowers worth the seeing. These are not all the Orchids in flower at Chelsea that are deserving of mention, but they must suffice to indicate to readers of the *Journal of Horticulture* how diversified and interesting is the entire display.—ORACHE.

High Street, Godalming.

DENDROBIUMS AT HOLLYCOMBE.

The Royal Horticultural Society.

National versus Metropolitan.

SPEAKING for the provinces, I think it can be said, without risk of serious disputation, that the greatest of all desires is that the Royal Horticultural Society should be much more broadly national than it is now, and less metropolitan. In assemblages of nurserymen and gardeners at the greater provincial shows conversation seems inevitably to centre on what is referred to as the "London Society." It is conceded that the headquarters of the Royal Horticultural Society must be in London, but at the same time what is described as a "London policy" is strongly objected to.

There is no sympathy among provincial Fellows with the idea that the society should devote its attention and means primarily to London shows, at which, in the very nature of the case, distant cultivators cannot exhibit on anything approaching equal terms. Little or no objection is heard to one great summer plant and flower show, as in the Temple Gardens, and one autumn fruit show yearly, as at the Crystal Palace. These are regarded as exhibitions of a national character, and visitors from various parts of the country are glad to attend them. The provision of a "Hall," however, that would drain the society of its resources for a series of shows throughout the season is a proposal that is only mentioned in provincial meetings of horticulturists to be condemned.

The present means for exhibiting new or rare plants, flowers, and fruit are held to be sufficient, and descriptions of such exhibits are read with pleasure in the gardening press; but no such pleasure is felt in respect to "displays" of the Covent Garden order, and which are neither new nor rare. Many country Fellows of the society are strongly of the opinion that no products, other than of a novel or instructive character, should be placed before the public at the society's expense, but that a charge should be made for the space occupied, as is done by the Royal Agricultural Society. If the matter were put to the vote of all horticulturists of standing in the kingdom as to the form in which the resources of the Royal Horticultural Society should be applied the verdict would doubtless be in favour of an adequately equipped and well managed garden in the country, and of a building in London sufficiently large for the placing of new, novel, or exceptionally meritorious products before the society's committees, and of such visitors who are specially desirous of keeping themselves up to date horticulturally. In other words it would be very much preferred that the meetings be educational rather than commercial in character, and national instead of metropolitan.

The advocates of a costly hall, which might bring the society to ruin, are, without so thinking, tending to lower the status of the Royal Horticultural Society by reducing it from a great national scientific and practical institution to the character of a London club.—A NORTHERN FELLOW.

A National Victoria Rose Day.

BOTH the communications of Mr. William Paul, on page 395, and of "A. C.," page 407, must have been perused with interest by many readers. Years ago I wrote in these columns—"The Rose is the national emblem of this country. When and by whom it was established in that prominent position I know not, but this I know, that it is worthy of the country, and, I think, also the country is worthy of the Rose." I shall be sure of this last proposition if a National Rose Day is established in honour of the venerable and much revered head of the nation. The greatest horticulturist in the Cabinet, Mr. Chamberlain, said only the other day—"The Queen has during the last few months added, if it were possible, to a popularity greater than that of any other monarch in history." We all know in what way, and by a graceful floral expression of devotion to such a monarch, would not the nation be also honouring itself?

The flower for this purpose must be the Rose. No other possesses in combination the same qualities of variety, beauty, fragrance, and hardiness. Whether, as from what Mr. William Paul has said seems probable (and there is no greater authority), the Rose was installed in its supreme position by the Romans or not, its right as England's emblem is admitted, and no other flower could be fittingly chosen for the purpose suggested by "A. D." a month ago, and enlarged upon on page 343. It is hoped that the idea, since it has received the approval of eminent rosarians, will be carried out.

"A. C." is presumably an antiquarian, and has a certain veneration for St. George. There is really no occasion to "throw him overboard." To me the Saint appears a misty sort of celebrity. In any case the honour of "paper flowers" would be of a very artificial, not to say shoddy, character. He is welcome to them; while to celebrate his

memory on April 23rd on a national scale, it would have to be done mainly by foreign Roses, and surely this would be somewhat of an incongruity for the "patron saint" of England!

The right day for a national Rose festival is the Coronation Day of Queen Victoria, whose worth and memory can only be appropriately celebrated by real genuine English-grown Roses. In nine years out of ten these may be had on 28th of June in every garden in the land that is capable of growing Potatoes, while millions could be supplied by commercial growers to meet the demand in large cities and towns.

This floral demonstration of the esteem in which her Majesty is held could be shared in by all creeds, parties, ranks, and classes in the community. It is worthy of thought, and might form a theme of discussion and collective expression of opinions in gardeners' associations and other meetings. It has even been suggested as worthy of consideration by the Royal Horticultural Society, and either this, or the National Rose Society, or both, might be effective agents in carrying it out. On their recommendation at the right time the general Press would be likely to make the project so widely known as to practically insure a successful response.—V. M. H.

Stealing Flowers at Shows.

MR. DE BARRI CRAWSHAY is too moderate in his references (page 415) to the despicable practice of stealing flowers from shows. It is not the first time the matter has been mentioned in the public press, and unhappily it probably will not be the last. It is, however, difficult to suggest a certain preventive of such malpractices. I personally should not have thought that anyone interested in growing Orchids—the aristocracy of the floral kingdom—would have sunk so low as to steal a single flower; but I was evidently in the wrong in assuming that the culture of a choice plant could bring the minds of all people up to a parallel level.

While no general principle seems possible, I think that the management of the Orchid section of the Drill Hall shows of the Royal Horticultural Society are of such nature as to favour the chances of a person securing a flower surreptitiously, and I think a change might be made in this individual case. One frequently sees the messengers, who fetch plants from the tables for the inspection of the committee, drop them down anywhere on their return, irrespective of their proper positions. Any person may then lift a plant, to put it in its rightful place, which gives opportunity number one. Then there does not appear to be any rule as to who should cut the flowers for the artist to paint. I have seen at least four different individuals undertake the task, which in my opinion should be strictly assigned to one person, or in his absence to a deputy, specially appointed by the chairman of the committee. All of those I have seen have been members of the committee, with whom I have the privilege of personal acquaintance; but there are others whom I do not even know by sight, hence if I saw someone taking a flower, I might reasonably assume that he belonged to the latter section. Thus we find opportunity number two, and probably there are several others.—AN OUTSIDER.

The Chiswick Trial of Tulips.

IN his eagerness to pose as a critic your correspondent "B. W." (page 417), passes quite beside the mark. He has evidently not read my notes, which he is good enough to acknowledge afford pleasant reading, very carefully, or he would not have gathered therefrom that the varieties named were absolutely the best in cultivation. They were not enumerated as such, but noted simply as having been honoured by the Floral Committee of the Royal Horticultural Society. At the same time, one or two of them are unquestionably superior to any in general commerce, and I would name Maes amongst the singles, and El Toreador amongst the doubles, as examples of this. As for the inclusion by "B. W." of *Tulipa cornuta*, I confess I fail to see the point of it. Species of Tulips were not under consideration in the slightest degree, but varieties of early or Dutch Tulips; but perhaps "B. W." does not grasp the significance of the difference. Let me assure your correspondent that he is not alone in his admiration of Keizers Kroon, in proof of which I would refer him to page 396, where I included this variety with Vermilion Brilliant and Proserpine as indispensable. Surely to state that a variety is indispensable is sufficient praise, without giving the colour of a flower with which every garden boy in the country is familiar.

I must certainly join issue with "B. W." when he questions the utility of a trial of Tulips. Perhaps, however, he prides himself on belonging to that new section of the gardening community which has grown with Mushroom-like rapidity during the past few weeks, and condemns trials *in toto*, and be it understood Chiswick trials in particular! We cannot all sit at home and preen our feathers in the confident self-assurance that we know every single and double Tulip in cultivation, or of any other flower for that matter. We thus, in our desire to learn, hail with pleasure a trial of any plant, fruit, or vegetable, and an inspection always adds to our store of knowledge. Dare I suggest that "B. W.'s" views would have been broadened had he visited, as I did, the Chiswick trial of Tulips with a mind eager to grasp the merits or demerits of the varieties grown?—F. W. H.

A Prolific Tulip Bulb.—I am sending a bulb of Tulip Mon Tresor, which has four blooms. As might be expected, the flowers are somewhat smaller than those on bulbs that produced one bloom only. Mon Tresor is a magnificent yellow Tulip of robust habit, and far superior as a bedder to either Yellow Prince or the Yellow Pottebakker, which are in beds in close proximity.—A. J., *Moor Hall*.

Aberdeen Botanic Garden.—Dr. J. W. Traill, the curator of the Cruickshank Botanic Gardens, Aberdeen, is at present employed in planning the beds, but it will be several weeks before the gardens will show anything indicative of their nature and purpose. Many plants have been received, but they are not yet arranged in the beds. The unfavourable weather during the past winter hindered the work considerably.

Strawberries in Abundance.—Outdoor Strawberries are coming into the English markets from Havre and St. Malo in good quantities. Home grown hothouse fruits have as a consequence, says a daily paper, declined considerably in price, and are being sold as low as 1s. 6d. a pound. It is quite possible that before the month is out they will be down to 1s. The French Strawberries are only partly coloured, but very large quantities may be expected shortly, as this season the crop will be a phenomenal one.

The Flora of Russia.—The St. Petersburg correspondent of a daily contemporary writes:—"An attempt is to be made to compile and publish a detailed account of the flora of the Russian Empire. The work will be divided into four parts, relating respectively to European Russia, Siberia, Turkestan, and the Caucasus with the Crimea. The Emperor has entrusted the directions to Mr. C. J. Korginsky of the St. Petersburg Academy, who will commence with the examination of the flora of Siberia, in aid of which a grant is to be made of 21,400 roubles."

Iris Susiana.—I was much interested in the magnificent specimens of Iris Susiana that were exhibited at the Drill Hall on May 8th by Messrs. T. S. Ware, Ltd. There were about a dozen and a half of flowers, and all were in the most excellent condition. I have many times tried to grow this handsome plant, but so far with little success, as my flowers were puny and inferior in colour. I have tried many systems on the advice of professional friends, but, so far, with no success. I wish readers of the *Journal of Horticulture* would give the details of any treatment they have found successful, as well for the benefit of others as for myself.—W. R.

Tree Butchers.—The remarks under this heading, which we take from the "St. Louis Star," are equally true of many London and provincial trees, but we thought they did things properly in America. "There are workmen and workmen in all branches of mechanics. There are competent and incompetent men plying the several trades. It is not the palette and the brush that make the artist, nor yet the paint pot that designates the painter, not the pruning hook, the hatchet, or the saw that speaks of the horticulturist, nor the trowel and the sprinkling pot that tell the story of the florist. In all callings some men excel, and alongside of them others miserably fail. Sir Joshua Reynolds, when asked by a young artist how he mixed his colours, answered, 'With brains.' That is the true touchstone of success in all callings. There is one class of fellows, just now plying their so-called calling in the residence part of St. Louis, who are wonderfully lacking in brains. They call themselves 'pruners.' To judge from their work they would better be called tree butchers—for that is what they have been doing for a week or two back, and are now doing out in the north-west suburbs—slaughtering, murdering some grand and stalwart trees that have stood and faced the storms of many winters. Next, almost, to murdering humanity, it is a crime to mutilate these stately Oaks and Elms. The city should pass a stringent law, requiring each man who professes to be a pruner to hold a license for doing such work, and debar him from receiving such license except upon the presentation of a diploma from a school of forestry, or at least a recommendation from some well known local individual thoroughly versed in 'treeology.'"

The Chestnuts in Bushey Park.—Visitors to Bushey Park on Sunday would be disappointed at the less luxuriant show of bloom in the famous avenue this year. Many of the trees, however, present a beautiful appearance. The cold weather is mainly responsible for this. A huge branch, some 60 feet long, covered with bloom, broke away from one of the largest trees in the park on Friday last, and several persons had narrow escapes from injury.

Rhododendron Thomsoni.—In referring to the Rhododendron garden at Rooksnest on page 419 of the last issue I omitted to mention the grand specimen of Rhododendron Thomsoni, which has recently collapsed. This fact is much to be regretted, as it was a really magnificent plant, and was described by Dr. Hooker as one of the finest he had seen out of doors. The plant grew to a height of 14 feet, and had a diameter of 12 feet; it had lived in the same position without the slightest protection for nearly twenty years, and when in flower was a superb object.—ZINGARI.

Seeds for Ladysmith.—During the worst stage of the siege of Ladysmith the Town Clerk wrote to an Australian gentleman to whom he had been recommended for a supply of garden seeds. Here is the letter:—"Town Office, Ladysmith, Natal, 19th February, 1900, 111th day of siege, 114th of bombardment.—Dear Sir,—Mr. ——— has informed me that if I write to you to apply for a few seeds the request will probably be granted. I simply require a few for my garden. If this could be done I should be very much obliged. We are hoping to get relieved soon. The present situation is very trying, and most of us are suffering from hunger." The Australian seedsman has sent on a variety to the now free-breathing town clerk, enclosing a message of congratulation on his philosophic coolness during a siege.

Briar Root.—The root from which the Briar root pipe is made comes into Leghorn cut into the shape in which it is exported to the pipe manufacturing centres, which are principally, at least as regards Italian Briar, St. Claude in France, Nuremberg in Bavaria, and various towns in Rhenish Prussia and Thuringia. The roots, which are sometimes of a circumference of 2 feet or more, are cut into blocks and then boiled. If there is any defect in the root which has not been discovered before the boiling process, the blocks are bound to split sooner or later. Briar root blocks are cut into about twenty-five different sizes and three principal shapes. The shapes are "Marseillaise," "Relevé," and "Belgian." The first two are the more usual shapes; from the "Marseillaise" blocks are cut the ordinary Briar pipes, which have bowl and stem at right angles, "relevé" blocks are cut into a shape for converting into hanging pipes, and "Belgian" blocks, for which there is only small demand, are shaped to fashion into pipes which have bowl and stem at an obtuse angle. A considerable quantity of blocks is sent to the United States of America, but apparently none to the United Kingdom.

Turf Walks in Gardens.—When I recently told Mr. Bowerman that I should call and see him at Hackwood, he replied in his characteristic way, "We have nothing to show you." Well, when I visit a garden I want no one to play the showman. I can always see for myself all that is good to see, and sometimes that which is not good. But at Hackwood everything when I looked in there on the 12th was of the former order, and notably the delightful turf walks of the great kitchen garden. I cannot conceive of any form of walk being neater, pleasanter, or more attractive in a kitchen garden than those at Hackwood, and in that great garden there is not an inch under gravel. Readily mown and edged, very smooth and firm, nothing could be nicer to walk or to look upon. One wonders why, after seeing how admirably turf walks answer at Hackwood, such walks are not found in many gardens. It was not less an interesting feature of this fine kitchen garden that not a weed was to be seen on it. Every part was as clean as could be. Crops in every direction were coming on admirably, though, like all else, rather late, for the situation is a somewhat cold one. The walls, and they are extensive, are capitally furnished. No trees could be better. What interest would attach to the judging of such a garden in competition with many similar ones on the same lines that cottage gardens are judged? Hackwood garden would indeed be hard to beat. It is now, and will be for some time, well worth a visit. The same excellent culture found outside is seen in the houses. The trees in the park and pleasure grounds are magnificent, and just now that they are clothed in their new leafage are most beautiful. There are few southern places that can excel Hackwood Park.—INSPECTOR.

NOTES & NOTICES

Recent Weather in London.—The latter portion of last week was not generally so cold as the preceding portion. On Saturday it was dull and threatening, and cultivators were hoping for a warm rain, which is much needed on dry soils. Sunday was warm with dull and bright intervals. On Monday it was decidedly warmer, but a rather high wind lifting clouds of sharp dust made walking somewhat unpleasant. During the small hours of Tuesday morning rain fell heavily, and continued in showers throughout the day. On Wednesday the showers were frequent and very heavy.

The Gardeners' Royal Benevolent Institution.—The committee has great gratification in informing the readers of the *Journal of Horticulture* that H.R.H. the Prince of Wales has graciously consented to succeed the late Duke of Westminster as president of the institution, and that H.R.H. the Princess of Wales and T.R.H. the Duke and Duchess of York have graciously consented to become patrons.

An Indian Hailstorm.—Darjeeling would seem to be particularly unfortunate in the matter of meteorological visitations. The correspondent of "Indian Gardening" there, writing on the 11th ult., says:—"You will be sorry to hear that we have had another disaster in Darjeeling; and from a gardening point of view, worse than that of September last. On Monday evening (9th ult.) we had a fearful hailstorm, which, although it did not last ten minutes, did an incredible amount of damage to vegetation and glass. The annuals, for instance, are battered out of recognition, while even Conifers had whole shoots knocked off. The Chrysanthemums and other perennials are mere sticks, and the Roses have had whole shoots taken off. The houses in Darjeeling present a woebegone appearance, as all windows with a westerly aspect are wrecked. Not in the memory of the oldest inhabitant has such a severe hailstorm occurred. Many of the hailstones were as large as eggs, and none smaller than walnuts. One can estimate the force with which the hail must have fallen, from the fact that over thirty panes of thick glass in the large conservatory at the Botanic Gardens are smashed. I had thought of sending you a list of plants in flower here, but—they are not in flower now!" A hailstorm such as this visited Simla in October, 1884, and the hailstones lay on the ground in some of the sheltered spots for nearly three weeks after the storm!

Carpet Bedding.—I observe from a pamphlet to hand from those enterprising florists Messrs. Cannell & Sons that they still believe in carpet bedding, as not only does the little book give numerous designs, but instructions as to what plants should be utilised in the filling of the beds. It would therefore seem as if carpet bedding is not yet quite dead, although it is rapidly becoming extinct. I notice that in many of our public parks and gardens where summer bedding is so admirably displayed, scarcely a single carpet bed is now to be seen. There can be no doubt that beds of this description have been popular in the past; but they absorb an immense number of plants, and need an excessive amount of attention compared with the results obtained in keeping these plants in rigid lines and quite dwarf. Practically carpet bedding may be described as the most artificial form of flower gardening to be found in horticulture. Certainly it is on a par with the hard formal trimmed hedges, topiary shrubs and trees, hard cold stone steps, and walls, statuary, vases, and other adjuncts still found in gardens modelled on the Dutch style. But there has been during the past twenty years a great secession from this description of gardening. Formality and stiffness have had to give place to natural formation and growth, and the beauty which Nature furnishes to plants, trees, and shrubs is now more generally encouraged and admired. Almost the only absolute element of formality found in modern flower gardens now is the smooth, close-shaven turf, but that is a feature that will never be abjured. Practically it constitutes one of the great charms of our lawn flower gardens. Even those who favour wild or grass gardening enthusiastically, yet like to have the lawn proper kept neat and close-mown. But the summer bedding is now more rugged in outline, more natural in appearance, and generally exhibits a great advance on the old carpet bedding.—A. D.

Gardening Appointment.—Mr. William Coomber, for the past two years and nine months head gardener to the Earl of Wilton at Houghton Hall, Kings Lynn, has been appointed in a similar capacity to the same nobleman at Cockley Cley Hall, Swaffham.

Mr. J. F. Hudson, M.A.—We have to congratulate Mr. J. F. Hudson on his appointment as mathematical lecturer at University College Bristol. This clever son of a clever father has for three years been assistant lecturer at Jesus College, Oxford, and assistant demonstrator of physics in the Oxford University laboratory. Mr. Hudson is a scholar of Jesus College, Oxford; he took first in Mods. in 1893, and first in Greats in 1895.

The Sleep of Plants.—Remarkable experiments were reported a short time back to the Cambridge Philosophical Society by Miss Pertz and Francis Darwin. If a "sleeping" plant is placed in a dark room after its leaves have assumed the nocturnal position, it will "awake" next morning—i.e., assume the diurnal position, in spite of darkness. Still more remarkable, if one-sided illumination causes the leaves to take oblique positions, they will resume such positions on awaking next day, though in darkness.

Jersey Potatoes Saved.—The latest news from Jersey is that after all, Jersey Potatoes will not be so dear this season as was at first feared. The supply will be not far from normal, but as there are indications of an unusually large demand prices may rule high. There have been extensive importations of German Potatoes to supplement the expected deficiency in the British product, one steamer alone landing between 12,000 and 13,000 bags from Hamburg at Goole. These are, of course, last season's products.

The Uses of a Churchyard.—Our clever contemporary "Truth," is responsible for the following:—*Aprpos* of the Ewelme Churchyard case, I have heard a rather good story said to have been told by a former Archdeacon of Suffolk visiting an out-of-the-way parish when the incumbent happened to be away, the Archdeacon was shown round by the clerk. On arriving at the churchyard he found a fine crop of Wheat growing in it. "Dear, dear," said the Archdeacon, "I can't approve of this, I really did not think that Mr. — would have planted Wheat in the churchyard." "That's just what I told parson," replied the clerk. "I says, says I, ye didn't ought to have wheated it. Ye ought to have tatered it."

Linnæan Society.—The Flora of the Andes was discussed at a recent meeting of the Linnæan Society by Mr. H. H. W. Pearson, with special reference to Sir Martin Conway's small collection of plants brought from Illimani, in the Bolivian Andes, in 1898. In consequence of the labours of D'Orbigny, Pentland, Meyen, Weddell, Mandon, and other botanists, the high-level flora of the mountains of Bolivia is better known than that of any other equally elevated region of the Andes. Many collectors have obtained plants in various parts of the Andes at elevations stated to be greater than 17,000 feet. Colonel Hall states that he saw four plants on Chimborazo in 1831 at "nearly 18,000 feet." These were two species of *Draba*, one of which, says a contemporary, was *D. aretoides*, and two composites. Mr. Whymper and others have thrown some doubt upon the determination of this elevation, and it is probable that it was over-estimated. Of forty-six species of flowering plants obtained by Sir Martin Conway, seven are from 18,000 feet or above it, two being as high as 18,700 feet. These, the highest Andine plants on record, are *Malvastrum flabellatum* and *Deyeuxia glacialis*.

Kidderminster and District Horticultural Society.—The above society held its monthly meeting on the 9th inst., under the presidency of C. N. Barr, Esq. The lecturer was Mr. W. H. Wilson of Moor Hall, Stourport, and the subject of the lecture was "The Potato and its Cultivation." Mr. Wilson said he had chosen this subject because it was one of general interest to all members of the society, the Potato plot being the common platform of gardeners. He traced the progress of the Potato from being a vegetable curiosity to a staple article of food. He advised deep cultivation in the autumn, giving a good dressing of partially decayed farmyard manure, not as food but to keep the soil in a good condition. At the conclusion of the lecture, on the proposition of the chairman, seconded by Mr. Coombs, Hagley, a hearty vote of thanks was passed to Mr. Wilson. The distribution of the Tomato plants (from seed supplied by the Royal Horticultural Society, with which the above society is affiliated), and raised by Mr. Whicker, F.R.H.S., one of the hon. secs., took place. The next monthly lecture will be on "Dahlia Culture," by Mr. Hawkins of Mitton, Stourport.

Coventry Chrysanthemum Society.—The schedule of this society for the show to be held in the Market Hall, Coventry, on November 6th and 7th is now before us, and will be forwarded to intending exhibitors on application to the secretary, Mr. J. Cooper, 31, Foleshill Road, Coventry. It is not a large schedule, but the thirty-one classes are sufficiently diversified to make an admirable show, provided the entries are as strong as they ought to be. There are four divisions subject to the usual restrictions. A sum of £12 is offered in three prizes for a 50 feet group of Chrysanthemums, this, with others for cut blooms, being open to all comers. The cottagers' section is mainly devoted to vegetables.

Royal Botanic Society.—The exhibition at Regent's Park on Wednesday, 16th inst., was like its immediate predecessors, a very small one. The authorities had vacated the usual position for the summer show under canvas, and the exhibits, which were of course mainly from trade growers, found ample accommodation in the corridor and conservatory. Amongst the more prominent exhibitors were Messrs. J. Laing & Sons, Forest Hill, who showed miscellaneous foliage and flowering plants; Messrs. J. Carter & Co., High Holborn, who contributed *Cineraria stellata* in considerable variety; Messrs. Barr and Sons, Covent Garden, who sent Tulips in fine form; Messrs. J. Cheal and Sons, Crawley, who exhibited sprays of flowering trees and shrubs; and Messrs. W. Paul & Son, Waltham Cross, and B. R. Cant, Colchester, both of whom were represented by magnificent Roses. Fruit trees in pots were staged by Messrs. T. Rivers & Son, Sawbridgeworth, and needless to say they were splendidly grown.

Agricultural Holdings Bill.—A special meeting of the council of the Central and Associated Chambers of Agriculture, called for the purpose of discussing the Agricultural Holdings Bill, took place on Friday afternoon in the Westminster Hall Grand Committee Room. Mr. V. Cavendish, M.P., presided, and there was a large attendance. Mr. Lipscomb, chairman of the Agricultural Holdings Act Committee, moved a resolution expressing a hope that the Bill now before Parliament would be amended in accordance with the recommendations adopted by the committee in June, 1894, and reaffirmed in the report of the committee adopted by the council on the 3rd of April last. The more important of the recommendations referred to are as follows:—1, That compensation for the unexhausted value of permanent pasture laid down by the tenant should be secured to the tenant; 2, That an outgoing tenant should be entitled to receive compensation representing the unexhausted value to an incoming tenant of two years' and older seeds, if a good plant, and if the land be clean and in good heart; 3, That power should be given to arbitrators to award compensation for long-continued use of manures; and 4, That both landlord and tenant should be required to give twenty-eight days' notice of claims, allowance being made for amendment of the landlord's claim in respect of dilapidations to buildings. Professor Long seconded the motion. The motion was carried by a large majority, and the meeting shortly afterwards terminated.

Royal Meteorological Society.—The first afternoon meeting of the present session was held on Wednesday the 16th inst. at the society's rooms, 70, Victoria Street, Westminster, Dr. C. Theodore Williams, president, in the chair. A most interesting paper was read on "The Witshire Whirlwind of October 1st, 1899," which had been prepared by the late Mr. G. J. Symons, F.R.S., a few days before he was stricken with paralysis. This whirlwind occurred between 2 and 3 P.M., commencing near Middle Winterslow, and travelling in a north-north-easterly direction. The length of the damage was nearly twenty miles, but the average breadth was only about 100 yards. In this narrow track, however, buildings were blown down, trees were uprooted, and objects were lifted and carried by the wind a considerable distance before they were deposited on the ground. Fortunately the greater part of the district over which the whirlwind passed was open down, otherwise the damage, and perhaps loss of life, would have been considerable. At Old Lodge, Salisbury, the lifting power of the whirlwind was strikingly shown by several wooden buildings being lifted up and dropped down several feet north-west of their original position. At a place eighteen miles from its origin the whirlwind came upon a rick of Oats, a considerable portion of which it carried right over the village of Ham, and deposited in a field more than a mile and a half away. A paper by Dr. Nils Ekholm of Stockholm was also read on "The Variations of the Climate of the Geological and Historical Past and their Causes."

The Weather in Dublin.—The climate of the Irish metropolis for the current month is far from being pleasant, although the earlier days were fine, but cold with sharp east winds. Latterly the days have been summerlike. The rainfall was slight. The advent of summer is discernible in the quickening pulses of the forests and hedges. In the gardens the impressions are deeply shown, as well in the rock garden as in every other section of the completely equipped estate. The orchards are in very good trim, and the trees in nearly all parts of the county around the metropolis having been heavily laden with blossoms. The vegetable garden is just beginning to show the results of more genial conditions.

Flying Beech Leaves.—At about four o'clock on the afternoon of Sunday, April 1st, my attention was arrested by the fall of numbers of dried Beech leaves. On looking up I found that the leaves were passing in large numbers from east to west, and as high as the limit of vision. Many appeared to be mere specks, whose height and motion promised them a journey of some miles at least. The shower continued for perhaps twenty minutes. The fall was noticed by many persons here, says a Wallingford writer in "Knowledge," who were unable to account for it, as there are no Beech trees within two miles at nearest. Probably the leaves had been raised by a whirlwind, and at a very considerable distance east of this neighbourhood. A friend, who was some three miles east of my station, witnessed the phenomenon, and states that by the aid of a field-glass he could see leaves still higher than those visible to the naked eye and yet felt that he had not even then reached the highest. The morning had been clear and bright, but at the time of this occurrence the east sky was covered with a thick thundery-looking haze. There was no surface wind. Barometer steady at about 30.2 inches.

Disastrous Weather.—The cold snap and the searching north-easterly wind that accompanied it have caused havoc in the orchards and fruit gardens. It is not much satisfaction to know that the visitation was by no means exceptional, nor does it tend to minimise the unpleasantness of the midwinter atmosphere to be assured by the authorities at the Meteorological Office that the present is by no means the most severe that has been experienced in May, and that the changes in 1891 and 1895 were much more violent, and caused enormous destruction in orchards and fruit gardens. The reports from the fruit-growing districts indicate that the frost has left its mark. In Kent the Plum blooms have suffered badly, and in places Strawberries have been severely nipped; but Apples and Cherries are fortunately said to have escaped. Wind and frost have seriously damaged the fruit crop in Oxfordshire. The outlook in Mid-Sussex is gloomy. Blight is setting in in Currants and Cherries, Strawberries are black, Pear blossoms are falling, and Plum blooms are turning yellow. Apples and Gooseberries, however, are unaffected, and Peaches grown in the open are well set. In the Windsor district both flowers and fruit are suffering. The Queen's gardens, however, are sheltered, and very little damage is reported, despite the bitter weather. Mr. Hugh Clements, the well-known weather prophet, says the summer will be a remarkably fine one. During July there will be a drought throughout the British Isles, with the exception of the west of Ireland. September will be a wet month.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

Rose Show Fixtures in 1900.

- June 13th (Wednesday).—York †
 „ 27th (Wednesday).—Salisbury (N.R.S.), Richmond (Surrey),* and Southampton.*
 „ 28th (Thursday).—Canterbury, Colchester, and Isle of Wight (Ryde)
 „ 30th (Saturday).—Maidstone and Windsor.
 July 3rd (Tuesday).—Westminster (R.H.S.), and Gloucester.
 „ 4th (Wednesday).—Croydon, Ealing, Farningham, Hereford, Reigate, and Tunbridge Wells.
 „ 5th (Thursday).—Bath, Norwich, and Sutton.
 „ 7th (Saturday).—Crystal Palace (N.R.S.).
 „ 10th (Tuesday).—Harrow and Wolverhampton.†
 „ 11th (Wednesday).—Brockham.
 „ 12th (Thursday).—Brentwood, Salterhebble, Woodbridge, and Eltham.
 „ 13th (Friday).—Ulverston.
 „ 14th (Saturday).—Manchester, and New Brighton.
 „ 18th (Wednesday).—Cardiff* and Carlisle.
 „ 19th (Thursday).—Birmingham (N.R.S.) and Helensburgh.
 „ 21st (Saturday).—Newton Mearns.
 „ 24th (Tuesday).—Tibshelf.
 „ 25th (Wednesday).—Newcastle-on-Tyne.†
 „ 26th (Thursday).—Bedale.

* Shows lasting two days. † Shows lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear in an early issue.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Ethel Brownlow.

A CHARMING bloom of this Rose at a recent Drill Hill meeting tempted one to try again in its culture. With us it was so unsatisfactory in growth that we discarded it. The most remarkable thing to form its great beauty is the substance of the petals. They are large, shell-like, and wonderfully thick. Its tints of flesh, rose, and yellow form a delightful combination. But Roses like this, Cleopatra and a few others, are not easy to succeed with, at least out of doors. I have read a description of a Rose—Horace Vernet—"that it is worth growing by the acre to obtain one perfect flower." Life, however, is too short for such Rose culture.

Bessie Brown.

At the exhibitions of the past year or two I had been struck with the beauty of this new variety as exhibited by its raisers, Messrs. A. Dickson and Sons, but as recently seen from pot plants I am not so enamoured. The petals appear wanting in substance, they are papery, and the white is a dead-looking tint. It may be, of course, that other growers than the raisers have not had time to obtain plants sturdy enough to give the blooms in their perfect phase. Somehow, this is not the only Rose that has failed to come up to expectations, after seeing it so fine at first. Has any reader been able to grow Margaret Dickson so grand as it was when first exhibited by the raisers a few years back? Or the three Marchionesses—Downshire, Dufferin, and Londonderry? I must confess they seldom please me, except in the matter of vigorous growth, which leaves little to be desired. Do they resent any but the Irish soil and climate which gave them birth?

The most satisfactory of the Roses raised in North Ireland by A. Dickson & Sons with us on a light soil is Mrs. R. G. Sharman Crawford. This grows and flowers beautifully, and is quite a favourite. Mrs. W. J. Grant is also fine. One might find fault with its want of vigour, but the exquisite blooms in any stage of development are so lovely that one's only thought is to plant more of it every year.

L' Ideale.

This variety is charming under glass. The habit of the plant is rampant, and when once established fills a considerable space in a short time. The combination of tints in the blooms makes it a most interesting sort; and in the bud state its shape is excellent. It must not, however, be thought a show Rose, the blooms are too small for this; but its distinct character in the way of colour makes it a Rose worth growing.—SPECIALIST.

Gardeners' Royal Benevolent Institution.

Anniversary Festival Dinner.

THE sixty-first anniversary festival dinner of the Gardeners' Royal Benevolent Institution, which was held in the Whitehall Rooms of the Hôtel Métropole, under the presidency of the Duke of Portland, K.G., P.C., G.C.V.O., on Friday last, was one of the most successful in the annals of the association. Not only was there a very large company present (about 160), but many distinguished gentlemen graced the festive board for the first time; it is to be hoped that they will become regular supporters, and that they will in the future lend their countenance and influence towards the extension of a charity whose aims and objects are so essentially meritorious. His Grace the chairman was supported by the Very Reverend the Dean of Rochester, the Venerable the Archdeacon of London, Viscount Powerscourt, the Hon. A. H. Smith-Barry, M.P., Sir Trevor Lawrence, Bart., V.M.H., Sir Walter Smythe, Bart., the Hon. Alban Gibbs, M.P., and Messrs. Jeremiah Colman, N. N. Sherwood, Harry J. Veitch, L. Salamans, Francis Ley, J. Robinson, H. Hicks, H. Youell, H. J. Adams, E. H. Sewell, W. Cobb, Jas. H. Veitch, J. Gould Veitch, Arthur W. Sutton, M. H. Foquett Sutton, W. Atkinson, Alfred H. Rivers, J. Lee, Charles Lee, G. Mouro, W. Assbee, F. W. Moore, Owen Thomas, G. Wythes, J. Hudson, H. Morgan Veitch, R. Dean, G. Gordon, and many scores of others almost or quite equally as well known in the realm of horticulture. We must also add the name of Mr. E. G. Hill, head of the important firm of E. G. Hill & Son, Richmond, Indiana, who may be said to have represented horticulture on the other side of the Atlantic.

The dinner, which was an excellent one admirably served, over, and grace having been said, the toast of her Majesty was given by the chairman, and it was received with exceptional enthusiasm. Then came from the chairman, "The Prince of Wales, the Princess of Wales, and the other members of the Royal family." In the course of a few remarks, his Grace paying a graceful tribute to the late Duke of Westminster, who had long been president of the Institution, announced that H.R.H. the Prince had testified again to his interest in the objects of the society by consenting to become its president. Not only must this be regarded as an honour to the Institution, but to the entire gardening community, and it is much to be hoped that H.R.H. will still further add to the honour already done by acting as chairman at the next anniversary festival dinner. Then, indeed, would the Gardeners' Royal Benevolent Institution leap from its present progress to the zenith of its prosperity. As further indicative of the interest of the royal family, the chairman announced that H.R.H. the Duke of York had consented to become a patron and H.R.H. the Duchess of York a patroness of the institution. Needless to say these facts were received with loud expressions of appreciation.

HIS GRACE THE DUKE then proceeded to the toast of the evening—"Success to the Gardeners' Royal Benevolent Institution," and at the outset thought that while expressing the great pleasure it gave him to occupy the chair, he should offer an apology for disappointing them on a previous occasion. As, however, he had been again invited, he might consider himself forgiven. He was, he averred, somewhat at a loss to understand why he should be chosen to such an important position, as he had few if any claims to be called a gardener. Rather had many years of his life ran in the direction of sport, including the propagation of hares and rabbits, which he was given to understand were not always the best of friends to gardens and gardeners. He wished everyone to understand that the possession of one of the largest gardens in the country was no unmixed pleasure—indeed, he had been bound to regard it as a white elephant. It had, he asserted, exemplified the saying, "the larger the garden the fewer the flowers," but now he was happy to know that under the supervision of one who had long been a supporter of the Institution the garden that had been a wilderness was fast becoming as a beautiful oasis, and he was gathering knowledge therefrom as would make him more fitted to preside over such a company. But, continued his Grace, whatever anyone's qualifications to be considered a gardener might be, everyone ought to do his utmost to advance the interests of the society. He, with everyone else, was bound to see the increasing importance of horticulture and agriculture in this country, and he considered that progress had been more rapid in these two allied sciences than in any other. This might be traced to several causes, such as those explorers who sent home from far distant lands beautiful trees, shrubs and plants for our gardens and greenhouses, and further to the splendid scientific works at Kew, and the persistent efforts of the Royal Horticultural Society. It was impossible to overestimate the value of such work, or to do too much honour to the workers. The diffusion of knowledge might even do a still greater good in winning back some of the population to the land. The rural school boards had recognised the importance of effort in this direction, and had included teaching on those subjects in their ordinary curriculum. His Grace then proceeded to place before those present the objects of the Gardeners' Royal Benevolent Institution, which were he said to assist necessitous gardeners and their widows with pensions or otherwise in their hour of need. Clearly and forcibly he dealt with point after point, and trusted in conclusion he had been able in some small degree to show how deserving of support the society really was. He hoped that not only all of those present, but also the public at large who

enjoyed the beautiful in life, would assist the cause that extended a helping hand to those whose labours were largely directed towards making the earth more beautiful and more fruitful. His Grace coupled with this toast the name of Mr. Harry J. Veitch, the treasurer of the Institution.

Mr. HARRY VEITCH thought it necessary to preface his remarks by saying to the regular attenders that there was little fresh for him to say, but asked them to remember that there were always new comers whom they were anxious to keep, and for whose benefit his remarks were made. Two points were, however, fresh to all—1, That it was the first time his Grace the Duke of Portland had been with them, and whom he desired to thank for his presence; and 2, They had to deplore the loss of their late president who, joining the Institution in its boyhood, had stayed with them to help and advise until it had reached a vigorous manhood. He referred to the honour that was done to the Institution and to gardening by the Prince of Wales in becoming their president. Mr. Veitch then placed before his auditors some striking statistics of the work that had been and was being done by the Institution, and looked for that support which would not only enable them to continue their present course but to enlarge their sphere of usefulness in a community where work was hard and pay not always large. He referred to the Victorian Era Fund and the Good Samaritan Fund, explaining briefly the aims and objects of each, and concluded by appealing in admirably chosen terms for assistance greater than had ever been given before.

Viscount POWERSCOURT in rising to support the claims of the Institution which had been so clearly demonstrated by Mr. Veitch, said he wished to pay a tribute to the memory of the late Mr. Malcolm Dunn, whom he had known and respected for many years as an able gardener and a straightforward, upright man.

"Horticulture" was placed in the hands of the Right Hon. A. H. SMITH-BARRY, M.P., who expressed his diffidence in undertaking such a task in the midst of an assemblage of experts. A knowledge of horticulture, he said, carried us back to the cradle of the earth and brought us forward through all ages to the present day, but notwithstanding the glories of the gardens of the Egyptians, Babylonians, Romans, Greeks, Japanese, Chinese, Moors, French, Italians, and other peoples, he did not think they could have had anything to beat the gardening of the present day in England. Horticulture, he said, was a science that all in differing degrees could enjoy. Mr. Smith-Barry coupled with the toast the name of the Very Reverend the Dean of Rochester, who, he said, was known the world over as an authority on all gardening matters.

Dean HOLE was, as is customary, enthusiastically received. He had, he said, passed eighty milestones on the journey of life; he had dined in royal palaces with the best Queen that ever lived, and he had taken tea in hovels of mud; he had numbered amongst his friends men famous in all the arts and sciences, but of them all he considered the greatest artists were those who beautified the land in which they lived. He related in his own inimitable way anecdotes of his life and the people he had met, and many a happy laugh was evoked during the speech. The recreation of horticulture, he affirmed, never palled; the love of a garden never faded. The garden, he said, was or should be a place of seclusion, repose, and restful peace, and as such he considered the change from stiff formality to natural informality a step in the right direction. He thanked them for their sympathy in listening to him, and wished them from his heart "the long and happy life of a gardener."

Mr. JEREMIAH COLMAN, Master of the Skinners' Company, gave the toast of "Our Visitors," for whom the Venerable the Archdeacon of London responded.

The subscription list was read out by Mr. G. J. Ingram at this point, and considering the calls upon everyone owing to the war in Africa, the famine in India, and the fire in Ottawa, must be deemed eminently satisfactory. Fears were entertained that it would fall very short indeed, but though it is not a record the efforts of the speakers were successful, as the total sum secured was £1980, which Mr. Sherwood undertook to make up to £2000. The principal amounts were—his Grace the Duke of Portland 50 guineas, Messrs. Rothschild & Sons 100 guineas, Baron Schröder, Mr. N. N. Sherwood, Mr. A. W. Sutton, and Mr. M. H. F. Quett Sutton each £50; Mr. R. Tait £36, Mr. W. Goldring £35, the Worcester Auxiliary £80, Mr. G. Monro, including the Covent Garden table, £123 9s. 6d.; Messrs. Fisher, Son & Sibray £26 5s.; Mr. and Mrs. H. J. Veitch each £25, Mr. J. Colman £26 5s., the Skinners Company £21, Mr. F. Ley £31 10s., Mr. J. Rochford £31, Messrs. B. S. Williams & Son £21, Messrs. W. Mackay, M. Gleeson, and J. Lambert each £20; Mr. R. Piper £15, Mr. J. Hudson 12 guineas, Mr. H. Rider £11, the Hon. Alban Gibbs, and Messrs. H. Tiarks, J. Laing & Sons, G. H. Richards, G. A. Dickson, G. Paul, J. G. Veitch, J. H. Veitch, and J. Wood & Son each 10 guineas, with numerous other smaller amounts, giving the grand total of £2000.

Mr. N. N. SHERWOOD proposed the toast of "Our Chairman," and in the course of his remarks pressed upon his Grace to induce the Duchess of Portland to become one of the vice-presidents of the Institution, which the chairman in replying undertook to do.

The proceedings were brought to a close with the toast of "The Secretary," to whose strenuous efforts the Gardeners' Royal Benevolent Institution owes a large measure of its prosperity.

Hardy Fruit Garden.

Disbudding and Thinning.—Where superfluous growths are yet soft enough to be removed with the finger and thumb, this method of removal may be adopted; but when the base of the shoots becomes hardened and woody, the shoots must be removed with a sharp knife, making a clean cut. The practice of disbudding and thinning out shoots in the early stages is practised as a ready means of regulating growth and avoiding a crowded state of the trees. Trees that are bearing a crop are much benefited by the timely removal of unnecessary shoots, for light and air are admitted more freely. On the other hand, trees in an unfruitful condition may in time be rendered productive if carefully disbudded and the shoots thinly disposed. The process of removal must always be gradual, as it is not desirable to rub or cut out large quantities at one time, which is likely to give a serious check, and might result in stone fruits gumming. Wall and espalier trees require attention equally all over, while bush, pyramid, and standard trees are prone to be crowded with growth in the centre. Neglect in carrying on disbudding and thinning with stone fruits results in injury to the successional shoots, which demand abundance of light and air to develop and become well ripened for future bearing.

Thinning Fruit.—Small and ill-placed fruit may be removed from Apricots, Peaches, and Nectarines. This may be done before the stoning process takes place, after which give the final thinning, leaving Apricots 4 to 6 inches apart, Nectarines 8 inches, and Peaches 10 inches. The small fruits have sufficiently developed on Plums to see which are swelling the most freely. All others may be removed, and those that remain to develop will be finer in consequence. Dessert Pears on walls, fences, and as pyramid trees may have the fruits thinned, commencing now to remove the small fruits, and those not well placed for swelling. The thinning of Cherries is not imperative, though to secure very fine fruit it may be adopted on small trees in the open and those on walls. Apples may eventually be thinned, large examples only being secured by reducing the number on a tree. Gooseberries may be thinned now to any extent, as the berries can be used for pies and tarts. The bushes, therefore, in this way usually receive all the thinning they require. The advantages of thinning are the better flavour and larger development of the fruit, as well as the strain upon the trees lessened, thus enabling them to build up good fruit buds for another season.

The Destruction of Insects.—Wall fruit trees are almost always attacked, more or less, with insects at this period, and some measures have to be taken in order to effect a clearance of them from the trees. A dry rooting medium is mainly the cause of the presence of aphides and red spider. In seeking for the cause of attack and finding it is dry soil, copious supplies of water should be given, and the surface afterwards mulched. At the same time destroy the pests. Aphides attack the points of shoots, the black fly usually doing so in colonies. One method of exterminating them is to dip the shoots in a solution of tobacco water, made by pouring half a gallon of water, boiling, upon 1 oz. of shag tobacco. Strain when cold, and add an ounce of soft-soap. The Gooseberry and Currant saw fly deposits eggs on the under sides of the leaves, and they forthwith hatch into small caterpillars, which soon make havoc with the foliage. Dustings of hellebore powder will destroy these, but as the substance is poisonous the fruit should be washed before using. Flowers of sulphur or fine lime are safer remedies. For the winter and codlin moth larvæ 1 oz. of Paris green to 20 gallons of water is considered the best remedy. The mixture during application must be kept well mixed, so as to insure even distribution, this being best effected by delivering it with a spray distributor. The first application may be given as soon as the blossoms fall, and the second a few weeks later. A sulphur and soft-soap solution is a good remedy for red spider, also frequent syringing, and maintaining the soil moist. The blistered and curled leaves seen on Peaches and Nectarines are not the result of insects, but of a fungus which is prevalent on trees growing in cold draughty positions. The leaves affected should be picked off, and if possible shelter afforded the trees in future from east winds.

Young Wall Trees.—With the trees now growing freely it is important that the growths receive proper attention in disposing them on the surface of the wall to the best advantage. Apricots, Peaches, and Nectarines bear on the young wood, therefore nail or tie in shoots of medium strength at full length. Apples, Pears, Plums, and Cherries which are to have a certain number of main branches disposed on the space available ought not to have them originated too closely, but in such a manner that they will run out a foot apart. The main growths of cordon trees may extend without stopping. Stop the side shoots of cordon Gooseberries and Currants when three pairs of leaves have been formed.

Stimulating Strawberries.—Immediately Strawberries have set a fair quantity of fruit, the plants will be assisted in developing them if liquid manure is given about twice a week. The drainings from cow sheds or stables are excellent for the purpose.

Fruit Forcing.

Melons.—When the fruit is cut from the earliest plants the old stem may be shortened back to a strong shoot near its base, removing as much soil as can be picked from amongst the roots without injuring them, supplying rather strong lumpy loam pressed well down and giving a good watering. If a moist atmosphere is maintained and the plants syringed in the morning and about 4 P.M., they will start freely, showing fruit in much less time than by planting afresh. If, however, the plants are affected with canker, or from carrying too heavy a first crop, a deficiency of water, or attacks of insects, are much enfeebled, it is better to remove them, thoroughly cleansing the house after taking out the old soil, and placing fresh sweet compost in ridges or hillocks, planting strong plants when it has been warmed through. Plants swelling their fruit should have a night temperature of 70°, though 65° or even 60° will do no harm when the nights are unusually cold and the days bright, 70° to 75° by day artificially being secured, admitting a little air at and above the latter, allowing an advance to 85° or 90°, closing at 80° to 85°.

Late Melons in Frames.—A useful crop of Melons may be obtained by making up beds now of any spent material, which from mixing and turning will generate a gentle warmth, placing over it frames that have been used for Potatoes and bedding plants, placing in each light a barrowload of rather strong loam, mixed with a fifth part of old mortar rubbish or road scrapings if deficient of grit, and pressing it down firmly. Into this when warmed through turn out a strong healthy plant, pressing the soil compactly about the roots, and giving a good watering. If the weather be bright shade for a few days. Seed may yet be sown to raise plants for frames at present occupied by tender bedding or other plants, but the Melons should be placed into their fruiting quarters with as little delay as possible.

Peaches and Nectarines.—*Early Houses.*—When the crop of Alexander or Waterloo Peaches, Advance and Cardinal Nectarines is gathered, the wood that has borne it should be cut out to the successional growths from their base for next year's fruiting, excepting those needful for extension. If the trees are too full of wood thin well, so as to admit light and air to the shoots, and thereby insure their thorough ripening. Early forced trees are liable to have the buds over-developed, and to cast them; therefore some growers leave the old wood until a later period to retard the buds, while others shade the house from bright sun with a similar object.

Covering the roof-lights with a thin wash of whiting and skim milk answers perfectly, using it as soon as the blossom buds are commencing to form, or from the fruit being gathered until the latter part of August. This is an excellent practice where trees suffer from over-maturity of the buds, and with proper regard to watering and keeping the foliage clean is effectual. Syringing should be practised in the morning and evening to free and keep the trees clear from red spider. The horders must always be in a thoroughly moist condition, as it is important that the foliage be kept healthy as long as possible. Admit abundance of air in the daytime where the fruit is ripening, and a little at night to prevent the deposition of moisture on the fruit, which is likely to induce decay at the apex, if not encourage an attack of "spot," *Glaeosporium laticolor*, which is sometimes disastrous to Peaches and Nectarines, as well as Figs and Grapes.

Succession Houses.—Only moderate artificial heat will now be required, in order to admit a free circulation of air. Remove any leaves that shade the fruit too much, raising the latter on laths placed across the trellis, so as to bring them with their apexes to the light. Attend regularly to tying in the shoots, stopping the laterals at the first joint as soon as made. Any shoots that cannot be allowed to extend without crowding or encroaching on others, stop at about 14 inches, exception being made of extensions. Shoots retained level with or past the fruit to attract the sap to it should be stopped to one or two joints at each break. Syringing must be practised morning and afternoon to keep red spider under, and the inside border attended to as required with water. Admit air early in the day, and in the case of houses with the best quality glass, or the inferior liable to scorch, in large panes a double thickness of herring or single pichard netting drawn over the roof-lights is beneficial in very bright and hot periods, preventing the foliage browning.

Late Houses.—Thin the fruit, leaving very few more after the fruits attain the size of Walnuts than will be required for the crop, up to which stage the thinning should be gradual, and avoid overburdening the trees. It is better to retain too few than too many fruits, fine examples being always appreciated, whilst the indifferently swelled and quality lacking are a source of complaint. There is no greater mistake than retaining more shoots than there is room for, as if the wood is not properly formed and is not solidified as made imperfect buds result. If aphides appear fumigate on two or three consecutive evenings, having the foliage dry and being careful not to give an overdose.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Triteleia uniflora (W. C. & S.).—The flower and leaf accord with the varietal form of the Spring Star Flower, *Triteleia uniflora* violacea, which thrives in a rich, well-drained soil in a sunny situation. It is propagated by offsets, the bulb being proliferous, and by seeds. If planted amongst short grass it holds its own for a season or two, but the plant and flower become smaller by degrees, not, so far as we have experienced, long surviving. Both it and the species form good bulbous plants for pots, flowering profusely in early spring, but the flowers remain nearly or quite closed in dull, opening only in bright weather.

Black Streaks in Potato (*Melfort*).—The brown or blackish streak in the flesh of the Potato is caused by the mycelial hyphae, or mycelium of the Potato disease fungus, *Phytophthora infestans*, and is the usual resting condition of the parasite. In this state the fungus passes over the winter in the Potato, it showing little or no sign of injury externally. The mycelium of the fungus has in the specimen before us entered the tuber at the heel or wire end, and passed to very nearly, yet not quite, the eye or growing end, the streak in no case being continued to the eye or eyes. There was as yet no indication of the mycelial hyphae developing. As to whether the mycelium would develop and ascend the plant by the stems is matter for conjecture, but it is certainly living, and may under favourable conditions give rise to the disease, or rather continue it in the plant of which the tuber is simply an underground continuation stem. We should say that a dressing of lime would be a good application to the land, and likely to be of service to the Potatoes, as well as preventive of the disease by fortifying the host plant or Potato. The spraying of Potatoes about earthing-up time would be advantageous.

Muscat of Alexandria Vine not Showing Fruit (W. L.).—The cause of Muscat of Alexandria not showing or bearing any fruit, is that the pruning buds did not contain bunches in embryo. From your letter we gather that the Vines are weak, and produced little fruit last season. Possibly, therefore, the cause of the imperfect bud formation was general weakness, especially of the basal or pruning buds. It follows that pruning to one or two buds in such cases gives no fruit, simply because they do not contain any; while the third or fourth bud, in case of the Vines having been shortened to them, give some fruit, and thus the buds correspond to the vigour of the leaf in the previous season. This long pruning or shortening to the best bud on each spur growth often affords a fair if not a good show for fruit, when close pruning on the same Vine does not produce any bunches. As you dug down 2 feet 3 feet away from the Vines and could not find any roots, it may be assumed that the root formation is very deficient, or that the roots have gone straight down, and are in a very unfavourable position for acquiring the essential aerated food. In a similar instance we have known an entire change effected in the condition of the Vines by removing the soil from about the stems to a distance of 3 to 4 feet early in autumn, not injuring the roots, but notching them about half through, and with the upper cut transverse, the notches being about 1 foot apart and on opposite sides of the root. This done, and the soil cleared away to the drainage, or at least 2 feet deep, place in good turfy loam, or a compost of twelve parts turfy loam, two parts old mortar rubbish, one part wood ashes, and half a part "nuts" charcoal, the turfy loam being chopped up moderately fine, and the whole well mixed. The soil should be made rather firm, and the operation performed whilst the leaves are on the Vines. As you have taken one or two young canes from the base of each Vine, you may cut away the old rods in their favour. As for manure, we fear little benefit would attend its use this season, as until the Vines have roots to appropriate it there is not much to hope for. However, you may use the following mixture:—Bone superphosphate three parts, sulphate of potash two parts, and sulphate of magnesia one part, mixed, applying 4 ozs. of the mixture per square yard, and pointing in very lightly. The dressing may be repeated in the course of six weeks.

Stop the laterals at the first leaf, and the sub-laterals to one joint as produced. The treatment practically amounts to renewing the rods, and having a diminished crop for some years, though increasing yearly. Whether it would be advisable to entirely lift the Vines is matter for your judgment, after carefully examining the border and ascertaining the state of the soil and drainage.

Adiantum Farleyense and Orchids Unsatisfactory (*Constant Subscriber*).—We have seen no healthier plants of the handsome Fern mentioned than were grown in a mixed plant stove. The temperature of this stove was never forced above 60° by fire heat, though it was often naturally, and properly, much higher under sun influence. The atmospheric moisture was in proportion to the heat, genial but not excessive, nor was the shading dense. Very much shade, heat, and moisture are not conducive to bold substantial fronds. Nor were the plants overpotted in spongy material, consisting in part of "Orchid peat." They were grown in sound loam, kept sweet and porous by crushed charcoal and sand, pressed somewhat firmly in the pots, small rather than large in proportion to the size of the plants. They were watered with judgment, supplies being given always when required, and never when the soil was sufficiently moist for healthy root action. If the soil, no matter what kind, be allowed to become too dry on the one hand for watering, or anything like sodden on the other, there can be no healthy growth. Possibly the soil in which your plants are lingering, instead of luxuriating, is sour. Many Orchids could not possibly remain healthy under the tropical conditions you describe. Some might grow very well for a time, but would need different conditions of a restful nature for solidification and flowering. It is, however, impossible to give useful advice on Orchids without knowing their names.

"Geranium" Plants Rotting just above the Soil (*H. C.*).—The "blacklegging" of Pelargonium stems is due to a fungus, Pythium De Baryanum, the malady being known to all gardeners as "damping off." It affects seedlings and cuttings of a great variety of plants. The affected part shrinks and turns black, hence the term "blackleg," decaying and spreading so that the stem becomes girdled and the plant collapses. Sometimes, however, the plant possesses the vital force to be able to resist its advance, then there remains only a wound on the affected part, and that healed over by new tissues, the parasite being completely thrown off or isolated. The disease extends from one plant to another in seed or cutting beds. The plants attacked and the soil between them becomes more or less covered with the mildew-like growth of the fungus mycelium, and the resting spores are produced and may be dormant until favouring conditions again arise for their germination and development. The fungus is usually introduced by leaf mould, it being of a saprophytic as well as parasitic nature. It is easily destroyed by giving the compost the conditions (heat and moisture) favourable to the development of the spores, and then, a few days later, exposing it to a very dry, hot atmosphere, so as to kill the delicate growth of the fungus. The preventive measures adopted by gardeners are well working the land, thin seeding or inserting of cuttings, keeping the plants stocky, giving plenty of air to avoid a stagnant atmosphere, and above all things preparing the compost some time before use, so as to have it sweet and free from the spores of the fungus. In your case we advise change of soil, though it is possible that watering the plants with an extremely weak solution of copper sulphate, say 1 part in 2000 parts water, or 1 oz. sulphate of copper to 12½ gallons of water, may arrest the fungus.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A Reader*).—1, Berberis Darwini; 2, Wistaria sinensis. (*R. Sussex*).—The flowering shrub is Spiræa Thunbergi; both the other specimens were pieces of the common Beech, Fagus sylvatica. (*G. J. W.*).—1, Pyrus spectabilis; 2, Prunus (Cerasus) Padus, the Bird Cherry; Rhododendrons can only be accurately named by comparison in a large collection. (*R. M. B.*).—1, Cattleya Mendeli, good form; 2, Lælia purpurata; 3, Cypripedium Lawrenceanum; 4, Dendrobium Bensoniæ. (*T. G.*).—Cerasus avium flore pleno. (*W. C. & S.*).—Triteleia uniflora, see page 448.

How we Feed Ourselves.

Not a day or a week passes when we do not see grave charges brought against the British agriculturist. These charges generally take the form of indictments of bad management—our methods of tilling are old fashioned—extravagant, and inutile. We do not get the uttermost that the land will yield; we are not as wideawake as

the foreigner, and so on and so forth. These reproaches usually come from men who are by no means as "up" in their subject as they think they are, but they serve their purpose, which is agitation against the present system and present workers. It is always advisable before addressing the public to make sure of the facts. We know very well how facts and figures may be manipulated, but still facts and figures are better than generalities—there is something to grasp.

Our population, instead of being stationary like that of France, is increasing rapidly; our land is sea girt, and therefore we cannot enlarge our borders to accommodate our family. We have done what we thought was the next best thing—established colonies and dependencies pretty nearly all the world over, and we expect that they help us in two ways—viz., relieve us of our surplus population and feed us with their surplus stores, for which we are ready to offer the best price. This, it appears, is not at all the proper thing to do. We should be self-contained, that is, be able within our own borders to produce enough of those feeding stuffs that the climate will allow us to grow. We are told constantly that we do not cultivate every available acre, that there is much of what is termed "waste land," land crying out to be tilled, that there is too little under plough and too much laid down to pasture; and that which we do cultivate we only do badly. We are not perfect, we know; but we fancy we can compare very favourably with those other nations that are held up as our examples.

Let us see what we do import, and the land needed for the production of those imports; let us count up our acres available and non-available, and strike a balance. Let us see per acre what we can manage to raise, and let us ask what other countries can raise per acre too—and then see who, acre for acre, has the best of it. Wheat comes first; it is allowed on all hands that we must have bread, and we find that we can only produce one-quarter of what we annually need. We do not say anything about the cost of producing that bread, but there is a pretty general opinion abroad that the grower will not become rich on his profits, and it is hardly to be expected that men are so large minded as to want to work without seeing some return for their labour. As meat eaters we find that we can supply about 62 per cent. of our yearly requirements. Much more meat is eaten now than formerly, and this is owing to the fact that the foreigner sends meat that he can afford to sell at a price to be within the means of our poorer population, a population that till recently were not great meat consumers. Owing to cheap bread and meat the consumption of the Potato declines rather than increases, and we practically supply ourselves. Of milk products we require about 45 per cent.; by that we mean butter, cheese, and condensed milk.

But there are other food products we are importing that by the casual inquirer might be forgotten. They are what might be termed indirect food products, and are classed under the following heads. They are needed, not for ourselves, but for our stock and for the purposes of fertilisation. We find in the list Barley, Oats, Rye, Beans and Peas, Maize, both whole and in meal, Buckwheat, Cotton seed, Linseed, Rape seed, linseed and cotton seed cake, other cakes and hay. Some of the Barley and Maize are for malting, but all the small second class Barley is used as feeding meal; we might put that down as about 11,947,000 cwt. per annum. We are very free users of the various oil cakes, and we also need much additional hay. Ninety million cwt. of feeding stuffs per annum would take a good deal of producing, and we fear that this production would be a puzzle that would perplex our many advisers. To get this food or its equivalent would require six million acres, and the question is whether we could produce the equivalent.

Very well, now let us see how much land would be needed to produce the Wheat, beef, mutton, and milk which we import. It has been worked out carefully by experts, and they have arrived at the following conclusions:—

	Acres.
Wheat would require	5,979,000
Beef	4,108,000
Mutton	2,176,000
Milk and its products	4,643,000
Feeding stuffs	6,093,000
	<hr/> 22,999,000

Now where are we to find these twenty-two million and odd acres? The total area of land and water in the United Kingdom is 77,671,000 acres, and of that 47,800,000 are under crops and grass. We cannot and do not suppose that much of the remaining twenty-nine millions are fit and suitable for cultivation; there is the water to deduct, the buildings, and the true waste lands. Of course some would say, "Plough up some of the grass." Well that would only be robbing Peter to pay Paul; we might get a little more grain at the expense of beef and mutton, and certainly at present we find if there is a bit of profit at all for the farmer it comes from his beef and mutton.

We should fare very badly without the oil cakes. Linseed has been given up for some time as an unprofitable crop in England, and though attempts have been made to revive that industry, they have only met with failure. Eliminate Maize from the bill of fare and you do away with a cheap and most valuable feeding stuff, and it will be allowed on all sides that Maize cannot be grown except as a green fodder crop in some of our warmest counties. We cannot even make an attempt at cotton cake, that is quite beyond our power, and yet cotton cake we must and will have.

We had intended to say a few words respecting the fallacy (for fallacy it is) that we do not get as much return per acre as some of our Continental neighbours; but the subject is too long to be treated of at the small end of a paper; we must keep it for another day. It is too bad to find our own people always belittling their own country folk.

Some of the calculations as to the production of feeding stuffs on mixed occupations are most interesting. They are based on the supposition that the land is of the best quality and under the best management. This is a table of quantities. Beef, 1200 lbs. annually will be produced from 65 acres; mutton 112 lb. from 0.64 acres; milk, 500 gal. from 20 acres. How many of us know what is our due, then, of the national butcher's bill? We fancy a good many of us fall far short of our proper share, 66 lbs. beef, 31 lbs. mutton, and 35 lbs. pork. Things (even butchers meat) are not evenly divided.

We fancy the greater production of vegetables of all sorts may have, in a small measure, affected the Potatoes. There has been a steady and large increase in the greengrocery of the kingdom. All manner of Broccoli and fancy vegetables are both abundant and good, and we see signs that our cooks look for and expect something beyond the homely Potato and Cabbage. It is good both for the health and the pocket that we include more vegetables in our dietary—in the past we have been rather too conservative, and have failed to appreciate at their proper value any but the very commonest and most easily cooked of the vegetable kingdom.

Work on the Home Farm.

We rejoiced too soon when we thought that the heavy rain would bring warmer weather, for the last week has been an unbroken record of north-easterly winds, cold and piercing, with sometimes we must imagine a touch of frost in them, for every kind of vegetation is looking more or less nipped. Barleys have distinctly gone back during the week, and have lost much of their promising appearance. Wheats are also showing signs of rust, and both are badly in want of more sunshine. It is late for top-dressing, but where Wheat turns very yellow, as the season is such a backward one, a light dressing of nitrate, say, 80 lbs. per acre, might be advisable. As regards farm work, the weather has been everything one could desire. The chief work now is ploughing fallows for Turnips, or rather Swedes. The land is turning up in beautifully moist condition, and much finer than was expected. Swedes could be put in well now, and no doubt many will be sown, especially in the north; but the land is hardly warm enough, and we should prefer to wait until mid-June rather than drill Swedes in cold weather. We have seen very fine crops indeed from May sowings, but not a May like this.

Mangold will soon be peeping through, and it must be side-hoed as soon as the rows of young plants can be discerned. Potatoes will soon be through, and if not already done must be ridge-harrowed. Such work went very well immediately after the recent rain; the large clots fell to pieces beautifully.

Pastures look greener, but there is only a short bite. The shortness of plant in the seeds is telling its tale now the young growth has a mouth always at it, and cannot make any headway. The Clovers laid in for hay having been relieved from stock for a month begin to look rather promising, and have stood the cold as well as anything. Meadows are the same; grass is growing where it has a chance. The cake merchant still drives a good trade; we see many waggons fetching cake to the farms. No doubt the price of meat is well repaying the farmer for his outlay. When a butcher has to pay 8s. 9d. per 14 lbs. for beef, and up to 10d. per lb. for clipped sheep, there is a good margin to buy extra foods with. As there is a strong probability of a striking decrease in the numbers of sheep recorded in the coming agricultural returns, farmers must make the most of their limited stocks. There is little fear of foreign meat having a very serious effect on the trade for some time to come. We hear that at the Yorkshire and Lincolnshire May hirings hands were almost impossible to obtain, and wages higher even than in the 1876 boom.

HARLOW STATION, G.E.R.

No. 1040.—VOL. XL., THIRD SERIES.

A Triumph of Hybridisation. Unique Offer.

3 NEW PASSION FLOWERS ALL DISTINCT.

Exceeding in beauty all others. Delicately Perfumed. Freely Blooming.

Raised at Oldfield Nurseries, Altrincham.

PASSIFLORA CLIBRANI.

This beautiful distinguished hybrid cannot be too highly commended. We claim it to be the ideal of all the Passion Flowers, it being a most distinct and handsome variety after the style of Princeps, but far excelling this variety. The petals are of a rich red wine colour always so attractive, rays of corona chocolate tipped with white. A charming flower in every respect. Perfectly free and vigorous.

PASSIFLORA FRAGRANT BEAUTY

As the name truly implies, this variety possesses a fragrance perhaps exceeding that of any other variety. A plant now in bloom at our Oldfield Nurseries commands the admiration of all visitors on account of the delicious perfume. The petals are pure white, rays of corona in two circles, centre chocolate brown, zoned white in the middle, upper portion bluish purple shades. Charming contrasts. Profuse bloomer.

PASSIFLORA OLDFIELD GEM.

This excellent hybrid possesses very considerable merit. It is a distinct handsome and free variety. The flowers are very large, and what has been said of the perfume of *Fragrant Beauty* we reiterate respecting this magnificent gem. The petals are pure white, delicately netted rose. The rays of the corona are in two circles, and being of a wavy outline they greatly enhance the appearance of the flowers. Centre rich velvety maroon, clear white zone, upper portion purplish violet.

Price 2/6, 3/6 & 5 - each; the set of three, 6/6, 9/- & 13/-

CLIBRANS', ALTRINCHAM.

"West's Plant Grip Stakes."

Everlasting double grip Stakes for instantly staking all plants. Send post card for Illustrated Catalogue.

"WEST'S PATENT VAPORISING FUMIGATOR."—Best and Cheapest, for being made of brass and zinc, will last for years. The stove only requires a little spirits to saturate the asbestos, so may be used thousands of times without wick or further trouble. Price complete with Stove and Bottle of Spirits, 9d., post free, to vaporise up to 2500 cubic feet.

"WEST'S EXTRACT OF NICOTINE" is guaranteed pure Nicotine, and three times as good as the best compound. It is not a compound, i.e., not a chemical substitute for Nicotine, but will make a compound equal to the best if desired at 2½d. per 1000 cubic feet. Price 7d. per Sealed Bottle of 1000 cubic feet, post free.

"WEST'S INSECTICIDE" can be proved to be the Best and Cheapest by sending for a free sample box.

"WEST'S POWDER WEED KILLER."—Best and cheapest. Guaranteed satisfaction. 1/6 tins post free.

For particulars of West's Patent "Ivory" Plant Labels, Soft Metal Tree Fasteners, S. M. Plant Clips, Gardener's Fountain Pen, Powder Diffuser (for dusting powder on plants), Wall Nails, Flower Grip Holders, Plant Pot Cocks, West's Fertiliser, West's Lawn Sand, West's Mealy Bug Destroyer, &c., see Illustrated Catalogue of West's Patent Garden Specialities, post free. Samples free, postage extra. All goods made on the premises of C. E. West, and delivered free.

"Orchid Culture," 3rd Edition, postage 3d.; gives full particulars of the cultivation of Orchids.

Renaissance of the Verbena.

WITH affectionate reminiscences for what, more particularly in the thirties, forties, and fifties, was considered to be the queen of bedding plants, it is with unfeigned pleasure that I observe there is a growing revival of the Verbena. My initiatory acquaintance with the then leading varieties was upwards of half a century ago, and there was no greater favourite of the parterre with me than the Verbena. Change is the fashion of the day, but the decadence of the Verbena, whether as a flower garden plant, pot plant, or as a florists' flower, can hardly be ascribed to that fickle jade, but rather to a deterioration of its constitution through over-propagation, and thus rendered it more amenable to disease, similar in effect to that of the Hollyhock. Thanks, however, to the hybridist, and to a careful selection of the seedling plants, combined with a generous cultivation, the Verbena has not yet become alienated from our gardens.

Where it is not competent to perpetuate named varieties for bedding-out purposes, seedling plants from carefully produced seed afford a pleasing feature by their multiform coloration and the soft fragrance with which they are sure to be more or less endowed. There is no other habitué of the flower garden that possesses so many attributes as the Verbena; it has a most accommodating habit of growth and multiform shades of coloration, eclipsing its compeer, the "bedding" Pelargoniums, and which is, perhaps, a venturesome assertion to make, considering the manifold attributes of the latter, and no bedding plant has withstood the test of time longer than the good old Purple King, for instance. Years ago, too, the Verbena was largely cultivated in pots for the decoration of the greenhouse and exhibition, and by a judicious selection of strong and healthy young plants, liberal treatment at the roots, and due attention to stopping and training the shoots, very fine specimens may be secured. To see a greenhouse from 50 to 100 feet long staged full of specimen plants flowering

No. 2696.—VOL. CII., OLD SERIES.

in shades of scarlet, crimson, purple, blue, and white, it will be readily conceded that no other decorative plant can afford so charming a display of beauty and colouration combined.

The exigencies of space forbid full details of the cultivation of the *Verbena* in pots, simple though it be, so that the repeated advice—a system of liberal treatment—must for the present suffice, seeing that starvation doubtless was responsible for having brought this once general favourite into comparative unpopularity. Moreover, it has been supplanted by new comers, such as the splendid variety of the hybrid tuberous *Begonias* and *Gloxinias*, lacking, however, the sweet fragrance of some of the *Verbenas*. As a florists' flower the *Verbena* was formerly a favourite, and a stand of cut flowers on the exhibition table was sure to attract attention, especially if from three to five trusses of one colour were put together and not crowded, but spread out to their fullest advantage, and kept apart with a little moss or cotton wool rendered invisible. If shown in single trusses they present a comparative meagre appearance. For the sake of uniformity, however, the individual size of the variety must be taken into consideration, and possibly three extra large trusses would present a better effect than more.

In evidence of the standard quality of several varieties of the bedding section cultivated from a quarter to half a century ago, and which, I believe, are still in existence, mention may be made of such as *Purple King*, *Géant des Batailles*, *Brillant de Vaisse*, *Crimson King*, *striata perfecta*, together with another striped variety, the sensational *Impératrice Eugénie*; add to these the very dwarf habited *Melindres splendens*, said to be a species brought from the hills of Buenos Ayres in 1827, and the first scarlet introduced of the greenhouse herbaceous section of *Verbenas*. It is also known by the specific name *chamædrifolia*, and there is an improved variety of it called *Melindres splendens grandiflora*. In the trade parlance the herbaceous *Verbena* is divided into two sections—viz., show and bedding, though many of the varieties in both will suit either purpose.

It may further be interesting to remark that in respect of show varieties mention should be made of two notable ones figured in the "Florist and Pomologist" of March, 1863, named respectively *Lord Leigh* and *Lord Craven* (two Warwickshire noblemen). The former was raised by Messrs. S. Perkins & Sons, Park Nursery, Coventry, being a chance seedling that came up in the open ground—a handsome variety, remarkable for the large size of its flowers, of excellent form, colour crimson scarlet, brightened by a clear yellow eye. The latter variety was raised by Messrs. Downie, Laird, & Laing, of Sydenham and Edinburgh; it was a remarkably fine variety, producing bold, well filled trusses of large, flat, well formed flowers 1 inch in diameter, and of a rich velvety, pucey-purple self colour. Both varieties received first certificates from the Floral Committee held at Kensington. Innumerable equally fine varieties have been raised since the breeding of those sensational varieties, and many of which are reminiscent of such noted raisers as Keynes, of Salisbury; Smith, of Hornsey; Eckford; of Sweet Pea fame; Wills, of Chelsea; and Robinson, of Pimlico, who raised the famous Robinson's Scarlet Defiance. Note, too, the late Mr. C. J. Perry, of Handsworth, Birmingham, who raised numerous varieties of great merit, but unfortunately owing to their cultivation in the greenhouse the majority of them were debilitated in constitution, Mr. Perry's chief aim having been the securing of fine blooms for exhibition purposes.—WILLIAM GARDINER.

PROMISED BOTANICAL TREASURES.—The British Museum trustees are undertaking a work of some historic interest in deciding to publish the series of copperplate engravings illustrating the plants collected in Captain Cook's first voyage, when Sir Joseph Banks and Dr. Solander were the naturalists, and in Captain Cook's second voyage, when the Foresters were the naturalists. These plates, which number more than 800, were prepared at great cost by Sir Joseph Banks some hundred years ago, and have never been published. Proofs only were pulled, and these are now in the library of the Botanical Department of the British Museum. Their publication will be of great interest to botanists.

"The Art and Craft of Garden-Making."

ILLUSTRATION is the mania of the moment. On every hand we note the prodigious progress which is being made in the reproduction of natural as well as of living objects through the medium of photography. In no department is this more noticeable than in the higher-priced magazines, which present us with the most charming representations of absent scenes and landscapes, but which unfortunately are not always accompanied with an equally fascinating and instructive text. If any class of literature has benefited rather than another by these new wondrous mechanical methods of illustration it is surely that of landscape gardening and horticulture. Painful indeed is it to look back some twenty, or even ten, years to the so-called pictures of garden and woodland, in which the trees often resemble those imported varieties from the Black Forest stocked in the Lowther Arcade for transplantation to the English nursery. Within a decade we seem to have traversed whole centuries of progress in black and white illustration—from the Chinese or block-book style of art to the full glory of the Renaissance.

But as we suggested above, there is, owing to this facility of illustration, an inclination in many quarters to subordinate matter to manner. Even in organs of a special class, which profess to administer scientific instruction, there are frequent lapses into mere *dilettantism*, where eked out and disguised a disproportionately small and unsatisfying text is set off by a perfect *embarras* of picture. Pleasant, therefore, is it to meet with a handsome quarto volume like the subject of this notice, which, while spreading all the present day charm of illustration over mansion, grove, lawn, river, and meadow, extends it also to matters of pure technique, accompanied by text of the soundest, practical, and most concentrated character.

In a volume of some 220 pages Mr. Mawson has treated of the "Art and Craft of Garden-Making." Pleasantly leading you through fifteen methodically graduated chapters (of which the first is a succinct history of garden-making in this country) he deals, amongst other topics, with the choice of a site, the making of gateways and fences, terraces, lawns, summer-houses, conservatories, fountains, lakes, kitchen gardens and orchards, landscape gardening, trees, shrubs, climbers, perennials, aquatic plants, and Ferns. In his endeavour to make this work terse, exhaustive, and complete within its comparatively small compass, Mr. Mawson has clearly spared no pains. He has consulted the best authorities and selected some of the best exemplars of existing gardens or of useful features in those gardens. Everywhere the text is sound and the diagram or illustration admirably adapted to explain the principle which the text seeks to inculcate. These diagrams and illustrations number in all 145, of which thirty-two are perspective and photographic views in leading gardens, twenty-four are garden plans, seventy-seven technical sections, sketches, details, and twelve garden designs.

In perusing these pages one is continually impressed with the desire of the author to make his work eminently useful to the reader. Authorities from everywhere are quoted, architects treat of the Oriental modes of trellis-work, all the best species and varieties of trees, shrubs, flowers, and grasses for permanent planting or annual bedding are indicated, types of devices and decorative adjuncts for the country-seat or villa-residence exist in profusion with instances, and when any construction or method of culture presents some doubt or difficulty, an expert's opinion often accompanies it suggesting a helpful alternative.

In the short space at our disposal we are unable to do complete justice to the very desirable treatment displayed in this volume. It is an object of pleasure as well as a mine of instruction, and fitted either for the drawing-room table or the use of a practical man who is capable of expanding an idea clearly presented, of an already familiar subject. We can highly recommend it to all who are interested in the delightful art of gardening, and trust we may yet have an opportunity of drawing special attention to some of the peculiar merits which it embodies.

* "The Art and Craft of Garden-Making," by Thomas H. Mawson. London Published by B. T. Batsford, 94, High Holborn, and Geo. Newnes, Ltd., Southampton Street, Strand. 1900. Price 21/-.

*Lælia purpurata Littleiana.*

THE varieties of the handsome *Lælia purpurata* that are considered worthy of a special varietal name are yearly becoming more numerous, and bearing in mind the beauty and utility of this Orchid no one can regret the fact. At the Temple Show last week examples of *Lælia purpurata* were not, perhaps, so numerous as is generally the case at this gathering, owing, of course, to the lateness of the season, but those staged were of high average excellence. The plant exhibited by Henry Little, Esq., Baronshalt, Twickenham, was in perfect condition, and the flower was so meritorious that the Orchid Committee of the Royal Horticultural Society recommended a first-class certificate. The form of one of the flowers is admirably depicted in the illustration (fig. 122, page 455). The sepals and petals are pure white, as is the lip, save for the crimson markings shown and the yellow crimson veined throat. *L. purpurata Littleiana* must be accorded rank amongst the finest Orchids that have been exhibited in London this year.

Odontoglossum Souvenir de Victor Hye-Lebrun.

Amongst the many superb Orchids that were exhibited at the Royal Horticultural Society's great Temple Show were several from Belgian growers; these were in the main of fine quality. Of them all, however, *Odontoglossum Souvenir de Victor Hye-Lebrun* (fig. 121) was the most excellent from the Continent, and one of the best in the whole exhibition. This hybrid resulted from a cross between *O. Harryanum* and *O. luteo-purpureum*, and distinct evidences of both parents are perceptible in the flowers. The sepals and petals are almost wholly brown, the yellowish green only showing occasionally. The front portion of the magnificent lip is pure white, and the basal part crimson. The Orchid Committee showed its appreciation of the flower by recommending a first-class certificate. This *Odontoglossum* was exhibited by Mous. Jules Hye-Leyse, and though it was packed away in an obscure corner of a particularly ugly case, it created almost if not quite as much interest as any other individual Orchid in the entire show. If all the Orchids sent by our Belgian neighbours equalled this they would be particularly welcome.

Oncidium monachicum.

This plant belongs to the same set as *O. serratum*, which species it resembles in habit. The spikes are long and many-flowered, the individual blossoms lasting well when cut. But the spikes should not be cut entire, as they do not absorb the water rapidly enough to keep the large number of flowers going. The sepals and petals are deep brown with a bright yellow frilled margin. Keep the plants in a cool house, and let the pots be rather on the large side but well drained. A moist atmosphere is at all times essential.

Dendrobium suavisimum.

Usually considered a variety of *D. chrysotoxum*, this plant is quite distinct, and a very handsome Orchid it is. The golden yellow blossoms occur on loose racemes from the upper part of the stems and last a couple of weeks in good order. It is a vigorous grower and a rapid one when it is at it, for the growing season often extends over a couple of months only. Still it will not do to dry the plants over the rest of the year, as this will lead to shrivelled bulbs and a weak state generally. A fairly regular intermediate temperature suits it best.

Dendrobium rhodopterygium.

A most ungainly-habited species, this *Dendrobium* is very pretty when in flower. It is very free flowering too, for the stems are almost completely hidden by the warm rose purple blossoms just now. In the lip there is usually a deep crimson purple stain that brightens up the flower considerably. It is a native of British Burmah, and likes ample heat during the growing season. Being strictly deciduous a long season of dry rest is necessary after the leaves have fallen, and the stout erect stems seldom suffer from this protracted drying.

That is always supposing they were well ripened in the previous autumn, for to get good flowers from an unripened stem is as unlikely as getting good fruit from an unripened Vine. It does not relish a lot of compost or room in the pots or baskets, and it is quite a mistake to pot the plants on when new material is given. Rather let the greater part of the peat and moss be removed, and the plants returned to pots of similar or only very slightly larger size. During the flowering season the plants may be placed in a drier and cooler atmosphere to conserve the blossoms.

Odontoglossum citrosum.

The true beauty of this fine Orchid is never seen at large shows, for it is seldom properly staged, the pendent spikes making it very difficult to pack or to show. Tied upright the plant loses much of its beauty, yet this is how it is exhibited in many cases. But as a plant for house decoration there is nothing much prettier in the whole Orchid family. The blossoms vary a good deal in colour, but are all sweetly scented, and although they last for a week or two in presentable condition, yet they are most beautiful in the first few days.

The culture of *O. citrosum* presents a special difficulty. It is perfectly at home in any fairly moist house kept at an intermediate temperature, not unduly shaded on the one hand, but sufficiently so to prevent injury to the foliage. Well rooted plants require abundant moisture supplies, and especially when growing freely in summer.

FIG. 121.—ODONTOGLOSSUM SOUVENIR DE VICTOR HYE-LEBRUN.

When the growths have fully matured and ripened it is best to lessen the root moisture by degrees, until in winter the plants are kept quite dry; so dry, in fact, that the pseudo-bulbs often shrivel to half their proper size.

Very early in the new year small growing shoots will appear at the base of the pseudo-bulb, but this must not be taken as a sign that moisture is again required. As a matter of fact, if water is supplied too quickly many of the plants will refuse to flower, but in a few weeks the tip of a flower spike can be seen in the point of the growth, and then water in plenty may be given to replenish the wasted bulbs, and to cause them to push the flower spike strongly. The way these grow is very remarkable, a few days after the first watering seeing an immense difference in their length.

Later, when the flowers are almost fully developed there is a risk of spotting these unless water is very carefully given. A thorough soaking in a pail or tank just before the flowers commence to unfold, and holding up the spikes while doing so, will carry them through the flowering period, and is better than risking watering from a pot. Newly imported plants of this species are very easily and quickly established, flowering often on the imported bulb, and rapidly making choice specimens. They should be potted first of all in clean crocks, afterwards given peat and moss in the usual way.—H. R. R.

London Gardens over Fifty Years.—No. 22.

Deptford.

THE name of Deptford does not suggest to us anything agreeable; we may link it with Rotherhithe, Wapping, and other low-lying places along the Thames, as offering no attractions to the gardener or the Nature student. Yet this unpromising suburb of London has improved of late, and even if there is less open ground than was to be seen fifty years ago, it is assuming a more cheerful aspect. One notable fact is, that after escaping various perils, a portion of the ground which Evelyn owned in the seventeenth century has been preserved for the public benefit. At Deptford it was that he had his little villa, an extensive garden, partly wooded, and "a pretty little greenhouse with an indifferent stock," so Gibson says. The nineteen acres of Sayes Court are the property of W. J. Evelyn, Esq., a direct descendant of the worthy author of "Sylva" and the "Gardeners' Almanac." Truly a pioneer of progress was Evelyn, for he also published "Fumifugium," in which he advised the removal of all smoky factories at least five miles from London, and suggested the planting of "fragrant nurseries and gardens" along the river near the City.

John Evelyn.

This good old gardener would, I am sure, be glad to see his Sayes Court benefiting the Deptfordians, and wish they had now all the 100 acres which was its original extent. When he took the place most of the land was open fields, a small part of it orchard. Evelyn must have soon planted extensively, for Lord Keeper Guildford called Sayes Court an example of his friend's book on forest trees. There are possibly trees still growing thereabout which are the descendants of Evelyn's plantations, but we cannot expect to find any trace of the glorious Holly hedge he was so proud of. Some time must have been required to produce this hedge, 9 feet high, 5 in diameter, and 400 feet long, proof against beasts and trespassers. It was not through this hedge the Tzar of Muscovy had himself wheeled, but one less thick; even then he must have been well scratched. Perhaps he suffered from some sort of skin irritation which the Holly prickles relieved. Tzar Peter also greatly damaged the wall fruit trees and killed several choice Phyllyreas, which it was then the fashion to develop into tall standards. Probably what is known as Deptford Park, Lower Road, was a part of Evelyn's grounds; this is a space of 17 acres, much of it laid out with grass. It was opened on Whit-Monday, 1897, by Dr. Collius, Chairman of London County Council.

Vanished Rivers.

Truly, in the good old times it was such fertile land at Deptford as rejoices the gardener, crossed by the Ravensbourne and sundry smaller streams that ended in the Thames. That river, London's "ancient highway," by its proximity was convenient for the conveyance of vegetables to market, and nearer than the metropolis were the numerous vessels of its port, where the produce of the fields found ready purchasers. Hence Deptford Rhubarb, Asparagus, Cucumbers, Onions, and various Cabbages had their repute fifty years ago, but the market gardeners have departed. Even at New Cross adjacent, about which I remember a large extent of open ground, the Directory now records only a single firm, that of Neve Brothers. Besides gardens New Cross had its fields of Clover and Lucerne, where butterflies sported or bees gathered honey. Newman, the great entomologist, tells us how he entered upon the chase of a clouded yellow butterfly amongst the Clover, and it went over into a market garden, so he pursued it there. But he was trespassing, and he himself was followed by a party of "female Hibernians," whose voices and gestures made him beat a rapid retreat.

Deptford's Nurserymen.

South of the Thames, the name of Myatt was at one time as familiar as that of Bagley or Gunter in the west of London, and a representative of this well-known family of gardeners may yet be found near Swanley, in Kent. Others, formerly well known about Deptford, were the Shephards, the Masons, with Messrs. Bryar, Reading, and Simpson. Mr. W. Brown owned a place expressively named Cold Blow Farm, and also land along Woodpecker Lane. The inhabitants of Deptford, half a century ago, had little taste for flowers, nor the means of purchasing them; therefore nurseries did not spring up about that locality. But New Cross had one, or possibly two, nurseries early in this century, perhaps from its being adjacent to one of the important roads into Kent and Surrey. It is said that the first nurseryman there was Cormack, the business being continued later by his sons. The place had some repute in London's time; its position is now unknown, for it has been closed many years, and left no trace.

Recently there has disappeared the nursery of Mr. J. Orsman, of Florence Road; this must have been nearly as old as that of the Cormacks. Manor Farm, Lewisham Road, was for a good while occupied by one of the Myatt family, vegetables and flowers were under cultivation here. In 1875 a sale took place, many thousands of Lilies, and various plants besides, were cleared, the land being required for building.

Hatcham Park, not far distant, is said to have had a good garden, while it was the residence of Mr. Hardcastle, about the middle of the century. What one might call rural signs are not unfrequent about New Cross, such as the "Dewdrop," the "Grasshopper," and the "Rosemary Branch." The last of these would indicate that herbs were cultivated hereabout. One of the facts we note in strolling at New Cross is the prevalence of Birches, a tree which evidently thrives on Surrey Hills. The Telegraph Hill, Hatcham, was secured as an open space in 1895, nearly £4000 being spent upon the laying out.

Churchyard Gardens.

Various steps have been taken to preserve intact such smaller open spaces as exist about Deptford. The "God's acre," for such it was literally, of St. Nicholas' Churchyard has been converted into a public garden; so, too, have the three acres of St. Paul's, but in it the gravestones are not removed. Amongst other churchyards adjacent to the river which have been greatly improved of late is that of St. Alphege, Greenwich, which was formally opened by H.R.H. the Duke of Cambridge in June, 1889, and is much frequented by the inhabitants. Then Mr. Passmore Edwards provided the funds for the laying out of the four acres of St. Mary, Woolwich. This ground is somewhat elevated, having fine views of the Thames. It was opened by H.R.H. the Duchess of Fife, in May, 1895. Nearly opposite Deptford, in the Isle of Dogs, the London County Council formed a small riverside garden that year, which proved a boon to the poor dwellers on that unattractive island, said to have been named from the dogs kept there by the kings who went hunting in the woods about Greenwich.

Greenwich Park.

Greenwich Park has for a long time had many visitors from far and near, a roll down the hill on Whit-Monday being esteemed the climax of enjoyment formerly—less so now perhaps. As a park, it is in some respects unlike all the other London parks. It used to be nearly destitute of flowers, except wild ones and a few herbaceous species; but by planting and bedding out, part has been made to appear more like a garden. The gales of recent years have been hard upon some of the older trees, for Greenwich Park surpassed even Kensington Gardens in its display of these. Especially are its fine Elms and its Spanish Chestnut avenues worthy of remark. Near the Observatory are some notable Scotch Firs; evidently at the first planting most of the trees were put in too thickly. By the Queen's permission 15 acres were added to this park in 1898, which had previously been reserved as the ranger's private grounds. Within a short walk again of Deptford and New Cross are the "Hilly Fields," Brockley, a lovely and elevated tract of 45 acres, upon which £5000 was spent in 1896. A useful little garden on the Ravensbourne, at St. John's, was opened about fourteen years ago by the late Duchess of Teck. Farther up the stream, a long strip of about 47 acres forms the Ladywell Recreation Ground.

New Southern Suburbs.

Amongst the suburbs that have grown rapidly this century a high place must be given to Lewisham. Since 1851 its population has increased from 16,000 to 104,000, the majority of them people fairly well off. As a consequence nurserymen and florists have increased in the district, we can reckon up ten, and over a dozen more about Lee and Blackheath adjacent. But we should seek vainly for the name of Willmott & Co., a firm that was the oldest existing at Lewisham, where they held a large extent of land, much of it being devoted to fruit culture. This nursery was founded by John Russell 150 years ago; he was highly successful, making a handsome fortune; he died in 1794. Lewisham formerly had many orchards of Cherry, Apple, and Pear, which were interspersed with fields of Strawberries. These have been cleared, mostly to make room for houses and streets, but, as is very apparent to travellers, much fruit is raised along the district farther east towards Dartford, in proximity to the S.E.R. loop line.

When mentioning some places in the Surrey suburbs of London, I omitted to speak of Dulwich, but a few miles from Charing Cross, yet a part of our century could extol its sylvan wilds, and rejoice that it was unspoiled by "barbarous art," whatever this may mean. But the builder has been busy; yet I found, not long since, a remnant of the old wood, and, by the generosity of the College governors, its park of 72 acres is secured for the public use permanently. The nursery of Messrs. F. T. Smith & Co. of West Dulwich has been carried on for half the century, and is an important establishment; some 7 or 8 acres, mostly under glass, are occupied by a great variety of exotics. Many of these are largely grown for producing seed only.

At Forest Hill, where if not a forest actually, a large wood existed in the memory of old Surrey folks, we find the nurseries of Messrs. Laing & Sons, who have carried on for some time an extensive trade in flowers, vegetables, and implements. Also the well known firm of Carter & Co. has land here, and two or three other nurserymen. Roupell Park Nursery, Norwood Road, is one of the few remaining near Norwood, the firm of Peed & Sons was formerly at Streatham.—J. R. S. C.

Seasonable Hints on Florists' Flowers.

Auriculas.

It is with somewhat of a sinking heart that I write what may be almost the farewell to the flowers I have so many years loved and cultivated. They were amongst those which in very early days I regarded as great favourites, and although there have been times when from one circumstance or another I have been obliged temporarily to abandon their cultivation, yet I have recurred to them again and again, and during the past thirty years they have had a very high place in my regard. I never had so large or good a collection of them as during this time, but there has been always one great drawback, there was no one in my immediate neighbourhood who knew anything about them, and it is but dull work to cultivate a flower when you can show them to no one who appreciates them but yourself. Some people ask to see your collection perhaps as a mark of politeness or curiosity, and when they have seen them they are ready to exclaim how pretty or how curious, but are unable to enter into any discussion of their merits. And now, alas! failing eyesight makes it imperative upon me to abandon the culture of the Auricula. It is a flower whose beauty depends upon points of form and colour, which can only be thoroughly appreciated by one whose sight is good. My collection is consequently now very much reduced, and will have to pass to some one who will be better able than I to appreciate and to cultivate them. This is a grievous trial for any connoisseur of some fifty years standing.

Regarding Auriculas, they have been very late in flowering this year, and should soon be repotted. A simpler form of compost is that which is preferable, and is now generally followed—namely, one-half of turfy loam about a year old, one-quarter well-rotted cow manure, one-quarter leaf mould, with a good sprinkling of sharp white sand. The tap root should be shortened, offsets which show any sign of root should be removed and planted in small pots, being ranged round the edges where practicable. In doing this they should be firmly potted, watered, and then placed in a close frame in a cool spot for a few days, being subsequently placed in the frame where they are to remain for the summer. These frames should, of course, face the north, in a situation clear of the drip of trees and shaded from hot sun. Attention must be given to cleanliness, and if aphides are present at all the plants should be cleansed. Perhaps the best plan is, before the process of repotting commences, to place them in a cold frame or pit and give them a fumigating with one or more of MacDougal's fumers. These are a wonderful improvement upon the old plan of fumigating with tobacco paper or cloth, and save the operator all the unpleasantness of the old system. Alpine Auriculas are not of so delicate a constitution as the edged varieties, and do not perhaps require such careful handling. They are also more inclined to give offsets, so that a collection is sooner got together. They have the advantage, too, of being much more easily raised from seed, and anyone who wishes to raise new varieties has the satisfaction of knowing that if they do not come up to the standard required they will make excellent border plants.

Carnations and Picotees.

Those who have wintered these beautiful flowers in pots and have planted them out in beds will now be preparing for the next operation, that of staking them. As far as I can judge, they have wintered well,

and if they have not been coddled will not mind the bitterly cold east wind which we are now experiencing. I see some of the shoots are spindling up for bloom, which I think somewhat premature, and when this is the case stakes should immediately be put to them. Here again we find the more correctly coloured and beautifully shaped flowers giving place to others more irregular both in colouring and form, but at the same time better adapted for the ornamentation of the garden. Very few persons now, I imagine, grow and bloom them in pots; but what pleasure plants so grown were to one in earlier days! and I question if anyone who follows the modern system can experience the delight which came to those who watched the development of each flower with its beautiful and regular marking.

Gladiolus.

It is too soon to do much with the beds of these bulbs, and all one has to do is to keep them free of weeds and the surface gently stirred. I have seen that the bulbs of the Lemoinei section, which have now

FIG. 122.—LÆLIA PURPURATA LITTLEIANA. (See page 453.)

been in my border seven or eight years, are rapidly pushing their way. It will be well to see before the shoots become too long that supports are applied to them, as if left to themselves they are very apt to be broken off by the high winds.

Pansies.

Here, again, a revolution has taken place; the old Show Pansy has been superseded by what are called the Fancy varieties. These originated abroad; but, like many of our florists' flowers, attained their highest perfection amongst our home fanciers. The flowers are of great size and brilliancy, and very irregular and fantastic in their markings, but they are quite as regular in form as the old Show varieties, and certainly more hardy in their constitution. I do not think, however, that the south of England is favourable to growing them in perfection, our summers are too hot and dry; and to see them in perfection one must travel to Scotland, or to the cool glades of Yorkshire, where climate and soil are both in their favour. The beds should now be kept clear of weeds, and where increase is desired

cuttings should now be taken, avoiding all pithy growth and choosing the small-sized shoots which come up at the base of the plant. It will be well, however, where much increase is desired, to cut off all the flowering stems which engender mildew, and trust to the plant throwing up shoots which will become young plants by-and-by.

Pinks.

The attempt to restore these once favourite florist flowers to popularity has not met with any success, but those who still grow them will now be thinking of propagation. They are somewhat difficult because they are so apt to damp off, and pipings, as they are called, as soon as they are firm enough, may be taken off and placed under bell-glasses in some shady position. The glass ought not to be removed for some time, and should any of the pipings damp off they should be removed lest any of the others be affected.

Ranunculus.

I am afraid this is another trying season for these beautiful tubers. They love moisture, and they have had but little of it lately. Should rain not speedily come the beds must be well watered, giving them a thoroughly good soaking, applying water between the rows and not over the bed. Here again one has to mourn over the lack of appreciation of these beautiful flowers, and the beds which I used to see in my boyhood and early manhood have to be looked for in vain.

Roses.

We are likely, I think, to have a very late flowering season, and the cold biting easterly winds which we are now experiencing are likely to exercise an injurious effect on them. The beds should be carefully gone over every second day and the maggot carefully hunted out and destroyed. If this maggot gets into close quarters with the bud it is sure to be spoiled. I have not as yet seen any green fly, but when it does come the plants should be syringed with water containing Gishurst compound or some other insecticide, and after this syringed with pure water. Those who wish to have really good flowers will now also disbud their plants, leaving only one bud to a shoot. It is necessary also to place sticks to any rapidly growing shoots to prevent their being shaken by the wind. Our exhibitions begin next month, and their prospects are not at present favourable, but everything will depend on the next three or four weeks. In the meantime let us hope that more favourable weather will follow this cold spell.—D., Deal.

Rhododendron Forsterianum.

THE group of hybrid Rhododendrons which has originated through crossing such lovely species as *R. Edgeworthi*, *Veitchi*, and *formosum* contains a large percentage of high-class plants, all of which are well worthy of extended cultivation, making as they do delightful pictures of grace and beauty for the greenhouse or conservatory in spring. The title of Queen of this beautiful group may well be accorded to the one under notice, for it quite eclipses any other variety in size, form, and beauty. It is a hybrid between *R. Edgeworthi* and *R. Veitchi*, and appears to be very scarce, though it has been cultivated in a few places for a number of years. The leaves are intermediate between the two parents, though bearing no very striking resemblance to either, the well-marked nerves of *Edgeworthi* being present, but very little signs of the brown felt on young wood and the under sides of the leaves which is characteristic of that species; in this respect the *Veitchi* parentage can be traced.

The flowers are upwards of $5\frac{1}{2}$ inches across, usually borne in trusses of three or four flowers each, or sometimes six on an extra strong shoot. The tube is very short, the petals spreading almost from the base. They are pure white with a lemon mark at the base of the upper petal. The margins are very prettily undulated, which adds greatly to their beauty. When seen from a distance the wide flowers with their prettily fringed margins are suggestive of the fully expanded blossoms of a Lily. An additional recommendation for this plant is the delicious perfume which accompanies the flowers, a few blossoms scenting a large house. When growing it should be kept tied in, as the growth is apt to become straggly. As it is a very free flowerer the buds should be thinned or the plant will soon become enfeebled.—W. D.

American Apple Outlook.—From advices to the "American Agriculturist" in response to special inquiries sent out, it appears that the prospect for the coming Apple crop is good in most leading sections. The blooming period has brought much promise, and so far as conditions at this early stage amount to anything, prospects are favourable for a liberal set of fruit.

Potato Culture.

MR. MOLYNEUX is quite correct in saying there is no excuse for growing inferior Potatoes when there is such a wealth of variety from which to select. Inferior quality, however, comes even from good varieties, when these are planted on land that does not suit them. As an illustration I might mention that these gardens once possessed a very poor character for Potatoes, their quality in the main being such that no one could eat them without complaining. This was attributed to the heavy manuring given the soil for growing them and other vegetables. When I took charge there were some forty sorts in stock, some of them very good in quality, but the maincrop forms grown in the greater bulk—Windsor Castle, Sutton's Seedling, Satisfaction, and Abundance—were those of which complaint was made the most freely. Obviously the remedy applied for—a better standard of quality—was a rigid selection of those that were found to suit the land, as proved by the cooking test, and the discontinuance of the growth of those that did not please. The question, at the present, of quality is never contested, or complaint made; indeed, the Potato has a character as good now as it was bad under the old order, which is, and must be, satisfactory to all concerned.

My mainstay is Snowdrop, with a few Beauty of Hebron, both of which are as good as can be found, and I do not think it possible to make the ground too rich for them, at any rate not with decayed horse manure. In a good Potato season I have lifted over a sack from each perch—lug it is called in the West—good sound produce from Snowdrop seed. The same variety is much favoured by cottagers, and this as well as Beauty of Hebron, form, in some cases, their main, as well as their late crops, and they keep soundly until late in spring when carefully stored. My latest introduction into the main crop or garden section is Syon House Prolific, and this promises both in point of quantity and quality to hold a favourable place. In the field Snowdrop fails because the culture is not sufficiently good for its constitution. The plough does not break the soil deeply enough, and the farmers' methods cannot be expected to equal spade work in the garden. Maincrop I have found to do best, being good alike in quality, free from disease, heavy cropping, and the tubers of a most serviceable size. During the whole winter I did not find a single diseased Potato, a fact that contributed largely to the extension of the supply and reduced labour.

In gardening as in every other vocation men have methods differing in detail one from another, and in Potato planting this often applies. While Mr. Molyneux will adopt a dividing space of 13 inches by 2 feet 3 inches, others will go to 3 feet between the rows and from 16 to 18 inches between the sets for maincrops. I have seen Snowdrops planted at the latter distance which completely hid the ground, and smothered Brussels Sprouts put out between them, and the crop, it need scarcely be said, was proportionate to their growth. I have not been able to compare artificial with natural manures so favourably spoken of by Mr. Molyneux for Potatoes, but I can point to land that has had neither for many years except that procured by burning up all garden accumulations, and the ashes and decayed vegetable matter spread over the ground at digging and planting time, and this not a heavy dressing by any means. I have found under ordinary farm planting that the rows are better with less space between them, because when subject, as they often are to periods of drought, the soil dries rapidly when exposed to the sun; with closer rows the sun is kept out from the shade afforded by the haulms.

Among early sorts I find Ringleader, Sharpe's Victor, Carter's First Crop, Sutton's Harbinger, The Sirdar, and Veitch's Ashleaf, are all good and reliable, and a greater range of variety among the first earlies is both interesting and instructive. Some are hardier than others in their foliage, suffering less from frost visits. I have seen a border planted with several early sorts, which after a late frost distinctly showed how varied was their resistance. While some would be badly damaged another would have almost escaped unhurt—that is, of course, after a moderate frost.

Seed-saving of these first earlies often presents some difficulty in getting sufficient stock for the next year's planting. I am able to get over this quite easily by allotting a portion of the border for planting the small tubers left. These will give tubers of a good size, which are stored as they are dug, and thus the trouble of selecting from those in daily use is entirely overcome, and all anxiety for the future removed. The ground is not manured for these unless it be very poor. There is always a proportion of small ones remaining after the selection of planting tubers has been made, and by setting these aside for the purpose more than one object is fulfilled, each of a useful kind. It sometimes happens when dependence is placed on small ones selected from the everyday digging that the seed stock falls short of the requirements of the garden. It is, therefore, good policy to provide against such contingencies, and plant the small, which would otherwise be thrown away as useless.—W. STRUGNELL, Rood Ashton.

NOTES & NOTICES

Recent Weather in London.—The weather during the past few days has been more pleasant and genial. Some steady rain would now be highly appreciated by the majority of metropolitan gardeners, and would do much good to all vegetable and fruit crops, as well as to the bedding plants, that are being rapidly inserted. The sun has had considerable power of late, and the ground is fast becoming dry. At the time of going to press on Wednesday it was dull and cold.

Gardening Appointments.—Mr. T. Whitfield has been appointed head gardener to E. Rhys Wingfield, Esq., Barrington Park, Burford, Oxon. Mr. G. H. Poole, late foreman Cleve Hill, Downend, has been appointed head gardener to W. H. P. Jenkins, Esq., Frenchhaigh Park, Bristol, Glos. Mr. Stephen Clarke, Trengwainton, Heanor, Cornwall, has been appointed, through Messrs. J. Veitch & Sons, head gardener to General Palmer, Glen Eyrie, Colorado Springs, U.S.A. Mr. Clarke is succeeded by Mr. Westcott, of Penalvern, Penzance.

Canada and the San Jose Scale.—The brief period during which the Canadian Government suspended the operation of the San José scale law and received nursery stock at certain ports of entry, fumigating the stock before its transportation was continued, necessarily restricted exportations, but assurances are offered of a further period of two or three months in the autumn, which will permit of the transaction of considerable business in the Dominion.

"I am a Boer."—Miss Dorothy Chute, a young Irish lady, was fined £3 11s. 6d. at Littlehampton recently for painting "I am a Boer" on a gate belonging to a nurseryman at Wick, near Littlehampton. Prosecutor said he owned 40,000 feet of glass close to the road. Defendant admitted painting the words because the prosecutor did not put out a flag in celebration of the relief of Mafeking. Col. Middleton, the chairman of the Bench, said he would not be called a Boer for £100. Defendant's conduct might have led to the prosecutor being lynched in the present state of public feeling or his property ruined.

"One and All" Flower Show.—This has now become one of the events of the horticultural world, and this year's show will, it is hoped, range in excellence with its predecessors. As usual, the exhibition will be in the Crystal Palace, and the selected dates are August 17th and 18th. There are upwards of 300 classes, which, needless to say, embody every crop that can be produced at that period of the year. This exhibition is one of the most admirably managed in the kingdom, and has a peculiarly high educational value from the fact that it encourages absolutely all classes of growers to compete. The honorary secretary is Mr. E. Owen Greening, 92, Long Acre, London, who will forward schedules and all necessary information to applicants.

The Amateurs' Practical Garden Book.—This publication of Messrs. Macmillan is one of their Garden Craft Series, which form a group of seven excellent portable manuals, prepared by Professor Bailey, of Cornell University, U.S.A. It deals in alphabetical sequence with the simpler garden operations and plants regarding which the young gardener may be seeking information, and also offers solutions of sundry difficulties inevitable in the pursuit of horticulture. There is, however, nothing in its design savouring of guidance. It seems to be intended as an "Enquire Within" for those who already have had a little practical experience of the art, and know something of flowers and vegetables. It is clearly and pleasingly written; and serves as a useful *résumé* of elementary gardening, which will be conned at leisure by those desirous of refreshing their memories. The cultural directions are short and to the point, but as they have reference to the climatic conditions prevailing in the north-east section of the U.S.A., they must be taken with reservation here. Many of the familiar names, too, of plants are of the American vernacular. Students and young enthusiasts will find it a very useful work to have, and its price, which is 3s. 6d., brings it well within the means of the class of readers to which it appeals. The style, like that of all books proceeding from this house, is unexceptionable.

The Horticultural Club.—We learn from the secretary, the Rev. H. H. D'Ombrian, that the next meeting of this society will take place upon the 19th June, and not upon the 5th as originally announced, owing to its coincidence with the Whitsuntide holidays.

Royal Horticultural Society.—The next fruit and flower show of the R.H.S. will be held on Tuesday, June 5th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Some of the Plants Exhibited" will be given by the Rev. Prof. G. Henslow, M.A., at three o'clock.

Draba gigas.—This very dwarf growing perennial is useful for the sunny part of the rockery. The thick, close growing, deep green leaves hang over the stones most effectively; the pure white flowers, too, are showy even at a distance. Although it grows freely it does not flower profusely for a year or two until it is thoroughly established in a good position.—B.

Marrowfat Peas.—Many visitors to the recently held Temple Show will remember the cone-like mounds of Green Peas that were arranged by Messrs. Sutton & Sons, and would recognise their great excellence for such an early date. We now learn that H.R.H. the Prince of Wales (president of the Gardeners' Royal Benevolent Institution) saw and admired them, and was graciously pleased to accept some for the Royal table.

The Percolation of Water.—The percolation experiments made at Rothamsted for about twenty years have shown that in the winter months more than half the amount of rain penetrates into the soil and is available for springs, while in summer this amount only reaches a quarter that of rain. Three gauges were used, each having an area of one-thousandth of an acre. The water was collected at three depths, and was always greater in quantity at 40 inches than at 20 or at 60.

Grapes from Spain.—Few people are aware of the quantity of foreign Grapes that come to this country. Take the exports from the small port of Aguilas, in Southern Spain, as an instance. We are informed that in a short time the exportation of Grapes will reach what before the epoch of the phylloxera might be considered its normal standard—namely, 1,000,000 barrels of Grapes annually. This year, including half and quarter barrels (after reduction to whole barrels), there have been 836,429 barrels of 55 lbs. each, or the astounding amount of 46,003,595 lbs. of Grapes.

Is It Manna?—A strange occurrence is reported by the "Delhi Post" concerning large tracts of Bamboo forest in Chanda, in the Central Provinces of India. Quite recently, and for the first time in the history of these forests, a gummy substance has been exuding from the Bamboo trees there. The supply of this is reported to be so abundant that the famine-stricken people are said to be making free use of it as a food. A quantity of this gum has just been sent to Dr. Watt, reporter on economic products, for investigation. Meanwhile, it is said to be a palatable resinous substance, sweet in taste, and resembling the Egyptian fungus supposed to be the Scriptural manna.

Kew Guild Dinner.—On Tuesday, May 22nd, the first annual dinner of the Kew Guild was held at the Holborn Restaurant, and never in the records of Kew has such a representative body of her sons been gathered together. At 7.30 the chair was taken by the director (Sir Wm. T. Thiselton-Dyer, K.C.M.G., C.I.E.), and slightly over 100 sat down. Of the number present about two-thirds were past Kewites, representing all parts of the British Isles, the continent, and the colonies. After an excellent dinner the chairman proposed the toast—"The Queen"—referring in a few words to the great part the Queen and other members of the Royal Family had played towards making Kew what it is to-day. Afterwards the same gentleman proposed "The Kew Guild," speaking with great enthusiasm of the beneficial effect the Kew Guild had had on Kew men, uniting all old Kew men in a bond of friendship and sympathy and keeping all its members in direct communication with each other by means of the annual journal. This toast was replied to by Messrs. G. Nicholson and W. Watson. Other toasts were—"Present Kewites," proposed by Mr. W. Pettigrew, and replied to by Mr. Girdham; and "Old Kewites," proposed by Mr. Dallimore, and replied to by Mr. Latham of Birmingham and Mr. Udale of Worcester. The toasts were interspersed with music, songs, and glees. At 11.30 the meeting dispersed, everyone regretting that the time had not been longer, and all expressing the opinion that they had never spent a pleasanter evening.

New York Society of Horticulture.—A representative gathering of horticulturists was convened a short time back at the New York Botanical Garden to consider the advisability of founding a horticultural society in New York. The Committees of the Council shall include:—(1) a Floral Committee; (2) a Fruit Committee; (3) a Vegetable Committee; (4) a Forestry Committee; (5) a Membership Committee; (6) a Finance Committee. These resolutions, says an American contemporary, and others dealing with rules of membership were accepted and referred for consideration to a temporary Council, when the report of the nominating Committee for permanent officers will also be received.

Eastbourne Flower Show.—Mr. Henry J. Capon, 75, Terminus Road, Eastbourne, has sent us the schedule of the show to be held in the grounds of Compton Place on Wednesday, August 15th, under the patronage of the Duke of Devonshire. There are seven dozen classes divided into three sections, which are open to all, open to amateurs and gentlemen's gardeners, and open to Eastbourne cottagers respectively. Generally speaking the prizes are good, and should insure an excellent display of produce, especially when we consider that practically every class of grower is catered for. The principal class is for eight stove and greenhouse plants, for which £14 are offered in three prizes of the respective values of £7 10s., £5, and £2 10s. The secretary, as above, will forward schedules and all necessary information.

Beckenham Horticultural Society.—On Wednesday, July 25th, this energetic society will hold its summer show in the Croydon Road Recreation Grounds, Beckenham, and considering the manner in which its committee is diffusing valuable information on gardening, we trust it will find strong support. The schedule which has been sent by the honorary secretary, Mr. G. R. Stilwell, Stanmore House, Southend Road, Beckenham, is most comprehensive, and brings the possibility of exhibiting within the reach of all growers. The prizes are not very valuable, but it is nevertheless anticipated that the exhibition will prove an excellent one in all respects.

The English Tulip.—A lecture was given before the Beckenham Horticultural Society on Friday, May 25th, by Mr. A. D. Hall, entitled "The English Tulip, its History and Cultivation," which proved to be one of the most interesting and instructive of the session. It was introduced at the close of the sixteenth century from Turkey, where some 153 varieties were catalogued, and was taken up by the Dutch, who, however, failed to make much improvement. English growers, from 1830 to 1850, when it was considered to be the flower of the day, made rapid strides, producing varieties that rank amongst the best of the present period. Seed sown takes six years to bloom, and the flowers are selfs or breeders, which at any time may change to perfected or rectified flowers, and once they change there is no reversion. Any good soil will grow them, and no insect pests trouble them. Planted in November they bloom in May, and should be lifted by the end of June. The particular characteristics of the various flowers were explained and beautifully illustrated by the bizarres, bybloemens, roses, and breeders from the National Tulip Society's Show. Messrs. Barr & Sons sent a collection of Darwin Tulips, and a hearty vote of thanks was accorded to Mr. Hall. —M. W.

Shirley Gardeners' Mutual Improvement Association.—The monthly meeting of the above society was held at the Parish Rooms, Shirley, Southampton, on Monday, the 21st inst., when Mr. B. Ladhams presided over a good attendance of the members. The evening commenced with a very interesting and practical discussion on flowering shrubs and trees, which was opened by Mr. S. Verdon, of the Red Lodge Nurseries, Bassett. He first dealt with shrubs and shrubberies, and then referred to some of the examples exhibited, of which there was a splendid display from the nurseries of Messrs. W. H. Rogers and Son, Ltd. A good debate ensued, in which several members took part, including the chairman, Messrs. Wilcox, Key Allen, F.R.H.S., Cleverley, Ekless, and Jones. Mr. Jones suggested that fruit trees should be more extensively cultivated on the outside of pleasure grounds. There was as usual a grand display of flowering plants exhibited from the Shirley Nurseries, whilst Key Allen, Esq., F.R.H.S., of St. Auben's, Bitterne Park, was awarded the society's certificate of merit for a very nice collection of Sweet Peas and a grand dish of Pea Tremendous. Three days later, on Thursday May 24th, the members had their annual outing, visiting London for the great Temple Show, whence they returned at midnight, greatly pleased with all they had seen.

National Rose Society.—The honorary secretaries of this important society favour us with schedules of the three forthcoming shows which are to be held at Salisbury, June 27th; Crystal Palace, July 7th; and Birmingham, July 19th, in addition to the show in conjunction with the Royal Horticultural Society on July 3rd. They also desire us to announce that a special general meeting of the members will take place at the rooms of the Horticultural Club, Hotel Windsor, Victoria Street, on Tuesday, June 5th, at 3 P.M. precisely, to elect an honorary treasurer in the place of Mr. T. B. Haywood, deceased.

Kidderminster Horticultural Society.—The schedule of this society, whose exhibition is to be held at The Larches on August 7th, stands alone as regards arrangement. As far as we can ascertain from the multitudinous interleaved advertisements there are 106 classes, and we trust intending exhibitors will allow themselves ample time to find what they specially require, and the rules appertaining thereto. We might suggest that a less involved system of arrangement would be appreciated by growers as well as by the reporters, who desire in writing of the show to follow the schedule. The prizes amount to about £100, exclusive of a silver challenge cup and medals. It is not made clear whether the challenge cup is offered for a group of plants or for table plants, but we may reasonably suppose it to be for the former. The honorary secretaries are Messrs. Rogers and Whicker, Brookfield, Blakebrook, Kidderminster.

Some Interesting Statistics.—The dutiable imports of plants, shrubs, and Vines into the United States amounted to 47,666 dollars in January, 1900, against 35,702 dols. in the same month of 1899. The free imports of seeds amounted in January, 1900, to 182,622 dols., against 107,657 dols. in January, 1899. The dutiable imports of seeds amounted to 121,317 dols. in January, 1900, against 67,401 dols. in the same month of 1899. The exports of seeds to other countries amounted to 435,103 dols. in January, 1900, against 301,103 dols. in the same month of 1899. The countries to which the United States exported seed were the United Kingdom, which received shipments to the value of 145,730 dols. in January, 1900, as against 125,872 dols. worth during the same month of last year. Shipments to France amounted to 21,679 dols. in January, 1900, as against 3658 dols. in January last year. Germany imported seeds from the United States to the value of 170,703 dols. in January, 1900, against 62,616 dols. in January, 1899. Other European countries received shipments to the value of 50,869 dols. in January, 1900, as compared with 49,980 dols. in January of the preceding year. A decrease is to be noted in the exports of seeds to British North America, being valued at 37,650 dols. against 48,306 dols. in January, 1899.—("Florists' Exchange.")

Chelsea "Physic Garden."—Probably there is no garden in England of greater interest than the Apothecaries' Garden at Chelsea, founded in 1673. The objects with which it was started were quaintly set forth by Sir Hans Sloane when he granted the ground to the Company of Apothecaries in 1722, and demanded that "the said garden may at all times hereafter be continued as a Physick Garden, and for the better encouraging and enabling the said society to support the charge thereof for the manifestation of the power, wisdom, and glory of God in the works of the creation, and their apprentices and others may better distinguish good and useful plants from those that bear resemblance to them and yet are hurtful, and other the like good purposes." The garden is about three acres in area, and has contained among other historic plants two Cedars planted in 1683, then only 3 feet in height. When they were measured again in 1766 the trunks were more than 12 feet in circumference, and the branches extended 40 feet in diameter. The garden contains a large greenhouse, the heating arrangements of which seemed to have caused much wonder in early days, for Evelyn, writing in 1685, remarks: "What was very ingenious was the subterranean heate, conveyed by a stove under the conservatory, all vaulted with brick, so as he (the keeper) has the doores and windows open in the hardest frosts, secluding only the snow." Last year it seemed not unlikely that this historical garden might fall a prey to the builder as the cost of maintenance entailed on the Society of Apothecaries was great, so that it is very satisfactory to learn that new trustees, those of the London Parochial Charities, have been appointed, and that it will continue to fulfil the purposes for which it was founded—the educational and scientific study of botany. It will be remembered by all readers of the *Journal of Horticulture*, that Mr. Thomas Moore, Editor of the "Florist and Pomologist," was for years curator of this garden.

The Oak and the Ash.—A record kept for the past eighty-four years has shown the accuracy of harvest forecasts drawn from the leafing of the Oak and the Ash. This year the Oak was the first to leaf, which indicates a dry and hot summer and a bountiful harvest, just as in 1898, when the Oak preceded the Ash in leafing several weeks.

Nature's Own Secret.—The quality which gives value to many great vineyards has never been explained. Two fields beside one another may have the same exposure, slope, and chemical constitution, and yet one will produce wine of first quality and the other wine of inferior grade. In the Rothschild vineyard near Bordeaux, for example, only a waggon-road divides the choice section which produces a world-famous vintage from a tract that is comparatively valueless.

Open Spaces in South London.—The grounds of the Primate's Palace at Lambeth were opened to the public on Saturday. They will be known as "Archbishop's Park." The main entrance to the park is in Lambeth Road, and there is a side entrance in Paris Street. The work of laying out the dismal churchyard of Christ Church, Blackfriars Road, as a garden has now been practically completed, and it may be hoped that one more sorely needed open space will be shortly available for the children of this crowded district of London. The graveyard is a large one, and has been tastefully arranged, a fence dividing the garden from that portion of the churchyard which actually adjoins the church. It is interesting to remember that this spot was once a private garden belonging to Queen Elizabeth.

The Alexandra Park.—The great scheme for securing the Alexandra Palace and Park for the free use of the people for ever has made much progress of late. Hornsey District Council began the good work by voting an additional £5000, at the same time expressing the hope that this would stimulate other districts to make an offer towards completing the project. On Friday the Wood Green District Council followed Hornsey's example, increasing their former vote of £25,000 by £10,000, making their contribution the handsome one of £35,000. Tottenham District Council was waited upon by an influential deputation, and it is hoped that a vote of £7000 may be the result. In Parliament all is going well. The Standing Orders Committee on Friday reported in favour of the Bill being brought in, and the House at once ordered it to be proceeded with.

The Phoenix Park, Dublin.—*Apropos* of the retirement of Mr. Dick from the post of superintendent of the Phoenix Park, a question in Parliament on the 24th inst. conveyed the information that Mr. Anderson, who, to quote Sir William Waldron's reply to Mr. T. M. Healy, M.P., filled an important post on an Irish estate for the past fourteen years, has been selected for the important office. Without the suspicion of a thought tending to detract from the merits of the gentleman who has received the appointment, it is a matter for regret, which Irish gardeners will share, that Mr. Kearney, the courteous superintendent of St. Stephen's Green Park, has been passed over. St. Stephen's Green Park has long been regarded as the last stepping stone to "The Phoenix," hence it is not only a matter for regret to all who know him, but a matter for surprise to many, that an Irishman so eminently fitted to rule over it has been denied the wider scope it would have afforded to his energy, skill, and experience.—E. K., *Dublin*.

A week of dull, cold, windy weather, with rain on four days.

Old-time Manuring.

A DIP into old-fashioned works on gardening and those of a kindred nature reveals the fact that, in theory at least, we are not so greatly advanced in the principles of manuring and the methods of application of fertilisers as one might suppose. We are certainly in a position to command manures in quantities comparatively beyond anything old cultivators could ever have dreamed of, and because of this we are perhaps less careful of materials possessed of manurial properties than they were obliged to be. Nothing, in fact, came amiss to them. When they write of dungs they almost always refer to the unmixed excrement of animals or of fowls, and not infrequently this was permitted to remain for a couple of years to rot before being considered fit to use, a preparation that explains the large proportion of dung put into composts, sometimes amounting to one-half. The employment of dung in a crude form was always condemned, though it would appear that the market gardeners round London transferred the material heaped up in the "lay-stalls" with which the streets of the metropolis were furnished previous to the great fire in 1666 directly to the soil, a practice which was considered by some writers to produce vegetables not altogether fitted for consumption.

Several old writers, following perhaps the teaching of Roman authorities, advise the formation of pits not more than 4 feet in depth, and of dimensions according to the quantity of material possible to be gathered together. Into this receptacle everything that would rot—rags, leather, bones—soot, lees of wine, the washings of dishes, night soil, weeds, leaves, clearing of roads and streets, hair, &c., was mixed with dung and soil, and when it had assumed the properties of a compost it was used in the garden. Pigeon dung dried and sifted was then as now, sown on the surface of the soil, and considered one of the most efficient manures. Lime was largely used where it could be easily procured, and Markham recommends it 300 years ago as one of the best of manures for certain classes of soil. A hundred years later lime-kilns were not at all uncommon for supplying lime for agricultural purposes. Sea sand was also considered of value as a manure, and the various strong growing Fuci, but more particularly *Fucus vesicularis*, cast on shore by the waves, have been employed time out of mind. One of its old names was "hempweed," indicative of the value attributed to it as a manure for Hemp. "Orewood" is another very old designation, and if we are to credit Markham, it was sought for in boats and gathered with hooks from the sea.

Pure salt was long ago highly esteemed as a manure, and is recommended by Lord Bacon for fruit trees. Evelyn, who used it as a weed killer on his walks, found its manurial properties to counterbalance its destructive ones, and came to use it only as a manure. I possess a curious pamphlet written to show the national importance of utilising salt as a manure, and how by its use England might be able to produce Wheat not only sufficient for her own use, but have a surplus to export. A Mr. Liveings in the early years of last century had a place of business at Bow Bridge, Essex, where he sold a "compound manure" at 2s. 6d. per bushel, which was said to be nothing but salt. Switzer, in a little treatise, "A Compendious Method for the Raising of the Italian Broccoli, &c.," commends this manure very highly for horticultural purposes, and a Samuel Trowell, gardener at Poplar, published a work on agriculture and gardening which is largely a puff of the same. The manure was scattered on the ground at about 8 cwt. per acre. Shortly after this time Baron Von Haake's composition was offered as a reliable fertiliser of farm and garden: 16 to 22 lbs. was the quantity of this recommended to be applied to an acre, and it was sold at 1s. per lb., "but to prevent trouble not less than 8 or 10 lbs. will be sold." The formula of William Ellis, a noted farmer of Gaddeston, for an acre of ground was 12 lbs. common salt, 1 lb. saltpetre, 20 bushels wood or coal ashes. Saltpetre (potassium nitrate) had long been in use as a manure. Bacon, for example in "Sylva Sylvarum," recommended Coleworts to be watered with salt water, "and much more with water mixed with nitre." "Hartshorne shaven" was by the same authority commended for "Mushromes."

It is noticeable that Bacon, as above quoted, was aware of the value of manure water, and as a fact it was in common use, if we are to credit old writers, not only in gardens, but also in field culture. Cow dung then, as now, was appreciated as a valuable aid when diluted in water. In some cases it would appear to have been literally only diluted, and was applied in a semi-fluid condition. A not uncommon way of using liquid manure was to fill vessels with it, place them close to the plants to be refreshed, and using a woollen rag as a kind of syphon, with one of its ends in the liquid and the other laid to the root of the plant, it slowly but surely soaked into the ground.—R. P. BROTHERSTON.

The Temple Show.

Although we accorded an exceptional amount of space in our last issue to the report of the Temple Show it was not found possible to include every exhibit. Those without the tents had to be omitted entirely, and one or two within. Of the latter the only one of material importance was the collection of *Nepenthes* contributed by Mr. Geo. Wythes, V.M.H., gardener to the Duke of Northumberland, Syon House, Brentford. These plants were splendidly grown, and should do much to point out to gardeners in general the value of *Nepenthes* for private establishments; as a rule they are somewhat neglected. The principal feature of the outdoor exhibits was found in the long frame of Water Lilies sent by Mr. Jas. Hudson, V.M.H., gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton. These comprised many species and varieties, and Mr. Hudson's reputation as a grower obviates the necessity of our saying anything further. Groups of various forms and sizes were exhibited by several nurserymen, and included amongst others *Begonias* from Messrs. Sutton & Sons; examples of topiary work from Messrs. W. Cutbush and Son; flowering shrubs from Messrs. J. Cheal & Sons; *Acer*s from Messrs. Cripps & Son; miscellaneous flowering trees and shrubs from Messrs. Fisher, Sons & Sibray, Ltd.; and shrubs from Messrs. J. Waterer, Ltd., Bagshot.

Phyllocacti.

So beautiful were the *Phyllocacti* shown by Messrs. J. Veitch and Sons, Ltd., at the Temple Show, that we are referring to them again to bring forward an illustration (fig. 123) that may be regarded as typical of light and dark varieties. Those who have known these plants for many years can see at a glance how marvellous have been the improvements made with them since Mr. John Heal took them in hand on behalf of the great Chelsea firm. We now have, in addition to greater size and substance, superb colours, such as were undreamed of years ago. These facts were amply demonstrated on the occasion of this show, and many were the expressions of admiration that were meted out to these gorgeous flowers. Unfortunately *Phyllocacti* are not grown so much as their striking beauties entitle them to be, but there can be no doubt that they are steadily gaining in popular favour, and it is to be hoped that before long they will be much more frequently seen. Only those who have grown them can appreciate the trials and troubles that must have come to Mr. Heal ere he could insure having such a splendid collection of flowers expanded on the same day.

Tuberous-rooted *Begonias*.

Tuberous-rooted *Begonias* must now be recognised as amongst the most valuable of our greenhouse plants for the greenhouse in the late spring and early summer months and for the embellishment of the flower garden at a later period of the year. Practically the whole of our leading seed firms have contributed to the plant's popularity by using all their skill in the improvement of the varieties in size, form, and colour. Amongst those who have concentrated their forces on the single and double tuberous-rooted *Begonia* must be named Messrs. E. Webb & Sons, Wordsley, Stourbridge, to whom we are indebted for the illustration (fig. 125, page 467) of a typical double variety. Among the recipients of the silver Flora medal at the Temple Show was the Worcestershire house, who arranged a bright collection of *Begonias*, together with some splendid *Calceolarias* and refined *Gloxinias*. Not only was excellence of strain discernible, but also skill in cultural details on the part of the firm's grower.

A Visitor's Comments.

It was hardly possible at this time of the year for a severer test of the popularity, or otherwise, of this great horticultural display to be furnished than the weather of Wednesday and Thursday last supplied, for the rain came down as it had not come down for a couple of months or more previously, doing enormous good elsewhere, but sadly handicapping the show. Yet, and in spite of the rain, what a crowd of people there was in the tents all the afternoons of those two days, so great indeed, especially on the first day, when the heavy rains allowed of no escape to the lawn, that locomotion was almost impossible; and what a well-dressed swell crowd also! Surely nowhere in London could one more fashionable have been furnished, just the sort of people to gladden the hearts of exhibitors, because so many came to order as well as to see!

On Thursday there was almost a repetition of the crowd that was

in evidence on Friday. I do not know, but it was abundantly evident that the Temple Show is at once one of the most popular, as it is one of the most fashionable functions of the London season. That fact speaks volumes for the position of the Royal Horticultural Society, and nobody has done more to create that position than the present council. That is a fact which those Fellows who seem anxious to thwart the council in their proposals, and possibly compel them bodily to resign—a serious calamity—when next important subjects come up for discussion in general meetings, should take to heart. The continuous accession of Fellows to the society's forces is also a remarkable tribute to the society's high position, and there can be no doubt but that such remarkable increase of Fellows has forced on the council the necessity of catering for the interests of these members by providing a noble national horticultural garden, that the prestige of horticulture and of the Royal Horticultural Society may be maintained in the kingdom.

Amidst all our glorification of Imperialism we must not forget that British horticulture has long been in the highest sense imperial, that it is every year becoming more so, and absolutely cosmopolitan. In spite of that fact our national horticultural garden is the poorest of its kind in the world. Our shows, of which the Temple is a grand sample, are splendid. So, too, are our nurseries, our market establishments, our private gardens, and our botanic gardens. But when we turn to our public or Royal Horticultural Garden we have to hide our heads in shame. Because of the great popularity of the R.H.S., the council realise that they owe a debt to the nation, and that debt they think can be most fitly discharged by establishing a great national horticultural garden. This may be a digression, but it could hardly be helped just now.

One undoubted fact in relation to the Temple Show is that for all ordinary purposes it is large enough. Could more room be furnished for visitors that would be good; but that, it is admitted, is impossible. It is therefore of no use to waste paper in asking for more space. It is not so much the extent of the show as the great excellence of what is seen there that is important. We find in many cases, and especially in the hardy plant and flower section, too much repetition; exhibits of that kind become wearisome. All interior exhibits one year should be rigidly barred the next, thus by so doing gradually weeding out poor things; also a severe limit should be put on exhibits that are reproduced year after year. *Begonias* expanding to 200 plants should be limited to fifty, *Gloxinias* the same, and hardy plants under the tents be specially reduced so as to enable novelties to be more largely introduced.

Cannot someone take the cue from Messrs. H. Low & Son's really beautiful *Schizanthuses* and give us a fine representative exhibit of the best annuals in pots? How attractive would they be! It is not so much the grand show of products with which every Temple Show *habitué* is familiar that takes pride of place, but something that is new or old newly provided, like the Gunnersbury Water Lilies, that command special admiration. It would be a great boon could things be rather more grouped in tents than is at present the case. Vegetables and fruits should be all in one, and specially so for the fruits, because then more immediately under observation; Tulips and allied bulbous plants, with hardy cut flowers and rockwork or alpine plants in another; *Begonias*, *Gloxinias*, *Calceolarias*, *Pelargoniums*, and similar florists' flowers in another, and so on, as then visitors seeking for special products would find them with ease, while to the unfortunate reporter this arrangement would be a great gain. Anything like classification is at present more difficult, indeed almost impossible. No doubt it will be claimed that the existing mixed or bizarre arrangement is to many pleasing, but it is at the same time rather bewildering.

What can be done with Orchids can be done with other things no doubt. The placing of the hardy trees and shrubs outside was a great gain and enabled exhibitors to show these beautiful plants to remarkable advantage. That some took great pains to not only arrange these artistically, but also to dress off their bases neatly, redounded greatly to their credit. Those who did not do so should be invited to leave their products at home. Another year the council cannot too strongly urge exhibitors to send not only of their very best, but not to crowd in any case, and to arrange all groups in the most graceful way. How superbly some of the Rose and Carnation groups were so presented; how terribly formal were many others?

No doubt these exhibitors will plead, "What, having regard to the narrowness of our space, could we do?" and that leads me to hold that if the council would concentrate all their show space in the long tents on the centres, and do away with the side tables, giving greater width to the centres, exhibitors of plants and some other products could do themselves far more justice, and the unhappy visitor would not be compelled to look on both sides of the walk at once. I hope next year we may see vegetables far more widely shown. It is not right such important garden elements should be so conspicuously absent, for when in good form they attract immense attention.—SCRUTATOR.

* Shows lasting two days. † Shows lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear in an early issue.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

For Walls.

ROSES are always popular, and especially so when grown as climbers on the walls of villa residences in town and suburban districts. As a rule Roses succeed the best and attain their most vigorous proportions as climbers when grown in the country rather than among the adverse influences accompanying culture near towns. But given a good aspect and good soil, care, and attention in pruning, training and keeping the growths clean will do the rest. All classes of Roses respond readily to generous treatment in soil, space, and aspect. These are important points to consider when planting climbing Roses. If these conditions are fully met the Roses must grow and produce wood, which the cultivator will so train and regulate that it may become well ripened, and flowering will certainly follow.

Good soil does not necessarily imply that special mixtures must be provided, but rather that the existing material be deeply trenched, adding some decomposed cow manure and a proportion of fresh soil, working the whole together. A position often assigned to Roses when planting them as climbers is within easy distance of the roots of large old trees. However good the soil is made the hungry roots of trees or shrubs will draw upon it for moisture, and with that goes a certain amount of good food. The roots of Roses are not able to compete with these, and hence the plants fall into ill health, poor growth being made which is infested with insects. The only thing which conduces to recuperate Roses in this condition is abundant moisture, giving first a copious supply of water, and afterwards liquid manure. The competition of foreign roots, however, is hard to overcome.

When the soil is suitable and kept uniformly moist growth will be free and vigorous, but to have the best results the space for training should be ample. The position ought to be a sheltered one, and not exposed to cutting draughts which are one of the causes of mildew. A sunny aspect favours the production of firm growth, where it is easily ripened. Weak liquid manure is beneficial while growth is being made, and also after the buds form and are swelling. The present time is suitable to make examination of the soil. If moist, liquid manure may be beneficially applied. The majority of Roses are, however, when growing against walls invariably lacking in moisture at the roots. Hence the safest plan is to give clear water first.

Syringing the trees forcibly with water from the garden engine on warm evenings cleanses the foliage, disturbs insects and prevents them establishing a stronghold on the growths. In training the growths dispose them thinly. The results will be better.

Among the best Roses for walls are Aimee Vibert, a Noisette; Cheshunt Hybrid, Gloire de Dijon, Madame Berard, Reine Marie Henriette, Perle des Jardins, Climbing Niphetos, Teas; and Victor Verdier, Jules Margottin, Countess of Oxford, Captain Christy, Bessie Johnson, and Glory of Waltham, Hybrid Perpetuals.—H. T.

Moss Roses.

Moss Roses possess most of the best characteristics of other Roses, and in addition are rendered specially attractive because of the mossy envelope which surrounds the buds. The variety *Blanche Moreau* is exceptionally well mossed. The mossing is caused by the enlarging and lengthening of the sepals, which are also finely divided along their edges and tips, giving that pretty and distinct appearance to the buds which is termed mossy. The sepals in the above variety extend beyond the bud to at least half an inch. The flowers are white and produced in clusters. The old *Blush Moss* also blooms in clusters, the flowers being white tinged with pink.

The *Perpetual White* is a finely mossed variety, producing splendid buds in large clusters. *Mousseline* is white tinted with pink, but as the bloom expands it assumes a pure white character. *Little Gem* is a novelty, a regular, well-shaped flower in miniature, crimson, large and double. Though small it is a vigorous grower. *Marie de Blois* is always thickly mossed, and the flowers, which are large and full, are of a bright rose colour. The *Crested Moss* is characterised by having its buds beautifully fringed. It also is of a bright rose colour. In addition to the white varieties mentioned, *White Bath* should be included, also *Comtesse de Murinais*, white, large and a vigorous grower.

A bright red variety flowering in clusters is *Baronne de Wassenauer*. It is one of the best, and a vigorous grower. *Captain Ingram* is a dark velvety purple not so popular now as formerly. *Eugène Verdier* belongs to the *Perpetual* class, which bloom more towards autumn than many of those named. It is a beautiful crimson large flower, and the growth is vigorous.

Moss Roses have a pleasing fragrance, and on this account a bed of them may be considered a special feature among the best of garden Roses. In a mixed collection of desirable varieties a few Moss Roses interspersed will lend a distinctive character to the group, especially when growth has well begun and the buds are prominent. The compact-growing varieties are best adapted for beds. In the cultivation of the Moss Rose the soil must be kept rich by liberal manuring. They ought always to have a sunny position in order that the wood may be well ripened. The thinning of shoots when crowded should be adopted. This is a means by which the wood is rendered firm and substantial, as vigour is not wasted in the feeding of weak and superfluous growth. Upon the whole close pruning is necessary, the best rule to follow being allowing vigorous shoots a greater length of wood, four or six eyes, and the weaker shoots which are not entirely cut out prune to two eyes.—ROSARIAN.

Tea Roses.

TEA scented Roses possess certain characteristics which are not so common to many other classes of Roses. In the first place the greatest range of colours is to be found among them, embracing various shades of primrose yellow, white, salmon, pink, red, crimson, pale rose, and blush. Then again they are deliciously scented, but this quality can also be claimed by others. In another point Tea Roses can hold their own. Their season of blooming often extends over the whole season. Good healthy plants, whether growing in pots, planted out under glass, or in the open, invariably produce bloom at the points of each new shoot, except this should happen to be strong new shoots pushing out from old wood.

This class of growth, however, is not wanted to bloom during the current year. On planted out specimens its appearance is welcome, as it indicates good root action and bright prospects of an excellent display of bloom the following season. The chief essential in order that it may bloom well is that the wood may become well ripened. Therefore, when this growth is produced, and it ought to be the aim of every cultivator to encourage it, every facility should be given not only to nourish and extend it in the course of the season, but at the same time to build it up firmly and assist the ripening process. These long strong growths break out in various parts of a plant, usually from the main stem or branches, and as it is so desirable to retain them, weakly parts may always be cut out to admit of training them in and providing the requisite space for disposing them thinly.

Vigorous plants, too, are always capable during the season of forming young wood of a branchy or twiggy character. This terminates in a flower bud or a cluster of buds, according to the strength of the growth. The continued production of these shoots prolongs the blooming season, and gives that interesting and useful character to the Tea-scented Roses, which is not equalled by any other class.

A vigorous condition of the plants is best maintained by insuring adequate root moisture and food stored in the soil. Water and liquid manure are therefore necessary at this season, especially where the border in which the plants are growing lacks moisture. If it does it will also be surely lacking in nutrition. Nothing can be added to produce a good effect unless the soil is first thoroughly moistened, when fertilisers should be added judiciously, and the results will repay.—E. D. S.

The World's Great Forests.—Canada heads all other countries in the extent of her forests. She possesses 799,230,720 acres of forest-covered land. Russia is credited with 498,240,000 acres, about 48,000,000 more than the United States. India comes next with 140,000,000 acres. Germany has 34,347,000 acres, France 23,466,450, and the British Islands only 2,695,000. This computation does not include Africa or South America, both of which contain immense forests.

Furcraea Bedinghausi.—A fine specimen of this Mexican plant has recently flowered in the Mexican house at Kew. It consists of a stem 1 foot long, surmounted by some fifty or more glaucous leaves 4 feet long by 2 inches wide. From the centre of the leaves the flower spike rises to a height of 10 feet. The main stem is bright red, bearing numerous bracts of the same colour. Side branches are freely produced which range from 18 inches down to 1 inch in length. From these side branches numerous narrow, tubular, pendulous, green flowers hang, the whole making a very conspicuous object among the surrounding plants. For the sake of its ornamental foliage alone it is worth growing for decorative purposes.—D.

Noteworthy Asparagus.—Mr. J. Udale has sent us from the County Council Experimental Gardens at Droitwich, a small sample bunch of remarkably fine Asparagus. The twenty-five heads weighed 4 lbs. 10 ozs., and some of the larger turned the scale at $\frac{1}{4}$ lb. each. The stems ranged from 9 to 12 inches in length, 4 or 5 inches being green and tender. Mr. Udale's method of culture was described and a fine specimen figured in the *Journal of Horticulture* of June 29th last year. Much of the success is no doubt attributable to the intelligent selection of crowns for planting, as raised from seed sown in April, 1896. Last year the heaviest bunch of twenty-five heads weighed 3 lbs. 8 ozs. This year the weight, as above stated, is 4 lbs. 10 ozs. So far as we remember it is the greatest weight that has been recorded in these columns. Has it ever been exceeded in this country?

A Bamboo Flower Stand.—One of the prettiest flower stands which has appeared of late is made of a piece of bamboo from 4 to 5 feet high, nailed upon a stand of two smaller cross-pieces in the shape of the letter X. A hole of about 3 inches deep is cut above each knot in the upright bamboo, and a natural receptacle for flowers is made in this easy fashion. Bamboo grows in sections, so that as there is a solid piece of wood between each portion of the upright stick, and nothing remains to be done but to pour water into the holes, and to place flowers in each. Lilac and Laburnum look exquisite when placed alternately in the bamboo flower stand, but almost any kind of foliage is effective when used in this way. The flower stand should be placed in the corner of a room or entrance hall, and the stand becomes almost invisible when it is nicely filled with flowers. These useful articles for wall decoration cost, says a daily contemporary, 3s. or 4s. when bought at a fashionable florists, but they can be made at home for a third of the price.

Carnation Mrs. Hemsley.—Whether this be of recent origin or not I am unable to say, but the name certainly is not a familiar one among the better known Carnations. I have only seen it growing in one garden, that belonging to W. H. Laverton, Esq., Westbury, Wilts, of which Mr. G. P. Bound has charge. The great charms of the flower are found in the clove-like scent, the unburst calyx, the beautiful crimson colour, and the large size. Its habit of growth is not so commendable, because it is tall and spreading. Mr. Bound overcomes this failing by giving it a position at the end of the house, where by the aid of a few strained wires the growths can be trained. It appears to be as free to root as it is in growth, which cannot be said of every variety. Those who cannot accommodate any except neat growers should avoid this one; on the other hand, where a small extent of wall can be given up to it in the manner indicated, and careful cultivation afforded, results cannot be other than satisfactory. Large pots are better avoided unless wall space is such as to accommodate its free growth.—W. S.

The Olive Fly.—A fortune awaits the man who finds a means of exterminating the Olive fly, for in Tuscany in a single year, says Mr. Vice-Consul Carmichael of Leghorn, he and his can easily do damage to the tune of five millions sterling. What seems to be wanted, says Mr. Carmichael, is that entomologists of experience should carefully study the habits of the fly with a view to finding out the hitherto undiscovered winter habitat.

Rhododendron Countess of Haddington.—In the Himalayan house at Kew two plants of this hybrid, planted to form one bush, were at the end of April making a fine display. It is said to be a hybrid between *R. Dalhousiae* and *R. formosum*. In the foliage and the shape of the flowers the former is readily traced, the influence of *R. formosum* being slight, but the colour is of a much deeper rose than is ever seen in that plant. The flowers are tubular, $2\frac{1}{2}$ or 3 inches long, by the same across the mouth, fragrant, deep red when in bud, bright rose when first expanded, fading to almost white before they fall. It makes a fairly compact bush, having none of the straggling habit of *R. Dalhousiae*, and is at the same time more floriferous than that plant. A cold house is best for it, as if grown in heat it soon becomes exhausted. It makes a free flowering pot plant, but is much better when planted in a border. Anyone with the room to spare in a cool greenhouse or conservatory could not fail to be pleased with this charming plant if they gave it a fair trial.—W. D.

Chiswick and Gunnersbury.—I was much struck with a most pertinent observation in relation to the Chiswick controversy made the other day by that able gardener, Mr. Jas. Hudson. He said, "Persons have thoughtlessly assumed that because we can grow things pretty well at Gunnersbury, that the same conditions exist at Chiswick; but that is absurd. Chiswick Gardens are not only closely surrounded by buildings, but are being more and more closed in every year, so that every season atmospheric conditions become worse. Here in Gunnersbury we are protected not only by belts of lofty trees, that help to purify the atmosphere, but we are in the midst of about 1000 acres of open land, for behind is the great expanse of Ealing Common, and all round a big area of land belonging to the Rothschild family, which they will not allow to be built upon, so that between the two places no fair comparison can be instituted." What a blessing the Gunnersbury estate is in the hands of people who are not subject to the building fiend.—A. D.

Seed Pockets.—The old time seed pocket, with its tightly sealed ends, does not appear to be worthy the notice of the inventors' attention, at least not generally speaking. One at least of the great seed houses has departed from this custom, and instead use a folding form, which is rendered much more accessible and handy at sowing time. In the case of many seeds, vegetable or flower, the gardener often finds it necessary to divide his stock, so as to make a second or even a third sowing, and to this the ordinary gummed pocket does not lend itself very conveniently, for once the seal is broken it is not always easy to repair. Hard seeds, unless securely enclosed, will often be found loose in the box or seed chest when frequently sorted, and thus become wasted. In the pockets which are hand-folded and ungummed seed-sowing is much simplified. As a protection against loss a small pasted label is used as a seal, bearing the season's date. Old customs die hard. Sealed pockets have been an old time institution, and this being so reform is slow in gaining headway.—S.

Kerrias as Town Plants.—This is always an attractive shrub in the spring months. Passing some small front gardens abutting the highway leading from Trowbridge towards Devizes I could not resist a halt to admire what to me was the prettiest effect I have ever seen from the shrub under notice. The garden, of an oblong shape, had low boundary walls on three sides, the house itself forming the fourth, and these were densely furnished with luxuriant growth and flower, which made a picture not easily described, but envied by many beholders. The double form was that represented, and certainly the example is one that in town gardens may be followed with both advantage and pleasure. Owners of small town gardens often vie with each other in securing the best "show," some in spring, others in summer. The same uniform results may not be obtained in every case, because in some gardens its growth is slow and weakly. Poverty of the soil is often the cause of this, and for which it is not difficult to find a remedy. It is the only instance I have seen where the *Kerria* has been so employed, and with such striking completeness, and a record is given of it so that others desirous of originality in planting may find a useful hint and act upon it in due season.—R. A.

A Day at Altrincham.

It was in 1872 that the groundwork of the now celebrated firm of Clibran & Son was laid, the beginning being in rather a modest way. Its development must be regarded as another proof of the fact that with determination and a business capacity, such as Mr. William Clibran the estimable head of the firm possessed, success must come in time. In addition to the Oldfield Nursery the firm now numbers the Principality Nurseries, N. Wales; 296, High Street, Bangor, N. Wales; the Stamford Nurseries, Bowdon; the nurseries at Hale; the seed trial grounds at Urnston, near Manchester, and the splendid establishment in Market Street, Manchester, wherein one can find seeds, bulbs, and sundries, in fact everything to satisfy the lover of a garden.

The Oldfield Nurseries.

These form the headquarters of the firm, and comprise a large number of glass houses, devoted to the culture of every class of plant. Several houses are devoted to the culture of Tea Roses, and no one could possibly wish for better results. Thousands of grafted plants were just on the move, others newly potted, until all the stages that go to make up plants to the large specimens of both climbers and dwarfs are reached. No trace of mildew could be seen, and the interest in looking over the stock was greatly enhanced by the pleasure of seeing only the best of men employed in their culture.

Ferns of every kind and variety were luxuriating in the greatest profusion, several new *Pteris* raised by the firm being pointed out with deservedly pardonable pride. The *Pelargonium* houses were a blaze of colour. The raising of new sorts is carried on to perfection so much, and the newer seedlings could scarcely be excelled for dwarfness of habit, freedom of flowering, and the size of the trusses. *Cyclamen*, *Primulas*, *Cinerarias*, and *Calceolarias* (fig. 124) are also a great speciality, and the highest conceivable praise one could give would almost fail to describe the hues and beautifully formed flowers so noticeable throughout.

Begonias of every section are most attractive, and the now popular tuberous rooted varieties were seen in immense numbers. At the time of flowering the grand house erected for them is one of the sights of the county. *Chrysanthemums* were past and gone, but the work with the young stock was being pushed on, sturdy, well-rooted plants being the result. An important work in the raising of new seedlings has been going on for years, until now the decorative, and more particularly the single section, stands almost unrivalled.

Many houses are devoted to stove and greenhouse plants, so well grown as to make discrimination almost an impossibility. New *Croton* seedlings seemed particularly promising, but the greatest attraction was the new seedling *Anthurium Fletcherianum*, a remarkable variety with the foliage of *A. Andreanum* but a spathe of an intense crimson hue, some of which measured 8 inches by 4 inches. Soft and hard wooded plants, scented and otherwise, climbers, and everything to suit either botanists or professional gardeners, are kept in stock. *Spiræas*, *Lilies*, *Azaleas*, and every class of bedding plant occupy many houses, whilst the popular *Carnation* finds itself in a similar position, the choicer varieties being represented by sturdy handsome plants in pots.

Many acres are given entirely to the growth of herbaceous and florists' plants and flowers, a well conducted system of division and rotation with thorough attention to position and compost, making the advice of the firm especially valuable. I could dilate at considerable length on the beauties, as seen previously, of the *Pyrethrums*, *Phloxes*, herbaceous *Pæonies*, *Delphiniums*, *Irises*, also of the charming *Alpines* in the rock garden, but the task of selection is too great a tax, so it only remains to be said that this section is replete with the choicest of varieties.

A double form of the old *Arabis alpina* was in evidence and should become highly popular. *Ivies*, *Clematis*, *Jasmines*, and *Passifloras* were observed in thousands. Of the collection of *Hollies* there seems to be no end; all sizes from mere rooted plants to the stateliest specimens take up several acres. *Aucubas*, *Laurels*, *Yews*, *Rhododendrons*, and *American plants* stretched in endless array.

No overcrowding is suffered, the constant lifting and turning of the plants leaving them, as any visitor would see, models of superior culture. Forest trees by the hundred thousand arrest the attention of every one, and it speaks well for the firm that many important orders from H.M. Commissioners of Woods and Forests have been received and executed.

Stamford Nurseries.

This forms an offshoot from Oldfield and must prove most valuable, the air being particularly clear and bracing. Various *Coniferæ* grow in the free manner which is so desirable. Some capital collections of plants were occupying the houses, and included *Latantias*, *Kentias*, *Ficus*, *Aspidistras*, *Pteris major*, *Adiantum cuneatum*, and *Lapagerias*, all in robust health.

Hale Nursery.

This has proved a valuable addition, for not only is the acreage great but the land is rich and good in many parts. Fruit trees have

found a happy home, nearly fifty acres being stocked with trees bearing the stamp of intelligent and careful culture. *Conifers* are again met with in beautiful condition. Many things of interest must perforce be omitted, but sufficient has, I hope, been given to allow readers of the *Journal of Horticulture* to judge for themselves of the interest and instruction that attach themselves to a visit to Altrincham.—A VISITOR.

Hydrangea Culture.

THERE are two ways of growing *Hydrangeas* for early spring flowering, the one by rooting points which have already formed flower buds in autumn, the other by means of cuttings the previous spring, and growing these on during the summer. Generally, I think, the latter is the better method to follow in private gardens, particularly where the plants are wanted in bloom from January onwards. The best forcing kind is the common *H. hortensis*, but the pretty white form, *H. Thos. Hogg*, though less amenable to forcing, is equally valuable for flowering from March, its white flower trusses being in even greater request than the former, and where wreath making forms part of the gardener's duties they are much used for that purpose.

The time to root the cuttings is during April or May, and points either from forced plants or those that flowered at their natural season in autumn are equally suitable. I root the cuttings in an ordinary propagating pit in a sand bed, and once they are well rooted they are potted singly into 3-inch pots, using for the compost a mixture of loam and sand. As soon as established the plants are transferred to a cold frame, and directly they are furnished with three pairs of leaves fully developed the tips are pinched, and half a dozen axillary buds are by this means forced into growth. Either previous to or after this, a shift into 5-inch pots will be required. *Hydrangeas* are by no means fastidious as to soil, and grow well in either a peaty or a loamy medium. The latter, however, is preferable, and if inclined to closeness in texture a little sand and decomposed manure incorporated therewith will facilitate growth.

During the summer and autumn months the plants succeed well in the open, and it ought at this period to be the care of the cultivator to produce large and broad foliage of a dark green colour, because it is on the quality of the foliage that the size of the trusses in the succeeding spring depends. If the leaves do not assume, or having it, lose this dark green tint, a little, but only a little artificial manure may be applied with advantage, but not later than the beginning of August. During September the supply of water must be lessened, in order to induce the young wood to harden and ripen, and by the 10th of October the application of water should cease, the plants meanwhile being preserved in a cool structure.

The plants that are most amenable to early forcing are those that retain their foliage, and which show the young trusses in late autumn. After resting a few weeks these may be started in November or December in a hot stove, applying water liberally with manurial help as required. They come in during January and February. Later stocks must be started as required, the chief points to be observed being a high temperature, with plenty of water. From March less heat will be required. If it is intended to retain the same plants for another year, the shoots when flowering is past must be cut hard back, retaining all the foliage possible, and starting growth slowly. Repot into 7-inch size, and treat very much as for the annual plants.

The one point those who are inexperienced are likely to fail in with these is allowing too many shoots to grow. It will be found that nine well-developed growths are as many as a plant is capable of producing and ripening. All others must consequently be rubbed off while very small. The shoots will, moreover, require to be supported, and at the same time regulated by means of short sticks, one for each.—B.

Allamanda Williamsi.—*Allamandas* have for many years been so closely associated with the name of Henderson that there are others which get slight notice. *A. Williamsi* is a very distinct, though less showy and useful, sort when compared with *A. Hendersoni*. It gives earlier blossoms than any other known to me, and forms a shrubby habit of growth. Shoots from hard cut-back plants produce clusters of small tube-shaped blooms within a foot from the point of issue. Such plants afford an agreeable change for indoor furnishing. They are continuous in bloom, and their sturdy growth and shrubby stature fit them admirably for vase work in the house, and they may be grown in pots of a size convenient for that purpose. One can visit many gardens without finding this *Allamanda*. For spring flowering, however, it certainly is an acquisition.—W.

Fig. 124.—CALCEOLARIAS.

Pine Culture.

PINES yield, as a rule, the finest fruits when they show these ten to twelve months from the time the suckers are potted, but some allowance must be made for the size of them when first started, also for autumn potted suckers, which have to make a part of their growth under adverse influences. Plants that were potted last September will now be showing fruit—if not, means should be taken to effect it. This can be done by subjecting those of that age not exhibiting signs of fruiting—a thick sturdy base, and the leaves commencing to open in the centre of the plant—to comparative rest for a period of a month to six weeks, lowering the heat at the roots to 75°, admitting air fully at 75° to 80°, and letting the temperature fall to 75° before closing the house for the day.

Little fire heat will be necessary, but it must be afforded to prevent the temperature falling below 60° at night, and to secure 65° by day. The plants must not be allowed to become excessively dry at the roots, but when water is needed supply it liberally. The smaller suckers of the plants placed in the fruiting pots this spring should be kept growing until they have filled them with roots, when, if it be necessary, the plants can be subjected to the same course of treatment as advised for the larger plants, and these will afford a successional supply of fruit.

The strongest suckers potted last March have filled the pots with roots and should be transferred when this occurs to their largest pots, as to retain them longer in small pots is detrimental to their after growth. Recently potted plants ought to have a regular bottom heat of 85° to 90°, and be thoroughly watered after potting if the soil be dry, and no more should be given until the soil becomes again in that condition, as it is necessary to exercise more care than usual at this stage, the state of the individual plants being ascertained before its application.

Growing stock, now making rapid progress, should be regularly attended to in every particular. Ventilate early in the day at 75° to 80°, to render the foliage dry before it is powerfully acted upon by the sun. Discontinue shading successional plants, but if very near the glass and the frames large, a light shade will be advisable in the hottest part of the day, also for fruiting plants with the crowns in close proximity to the roof.—PRACTICE.

Notes on Figs.

THE fruit now ripening on the early forced planted-out trees must be kept from damp throughout the whole of the process, affording a free circulation of warm dry air, and a night temperature of 65° to 70°, 75° to 80° by day, and with sun heat 80° to 90°. Figs ripened in a close moist atmosphere are insipid, but those perfected by full exposure to light and in a favourable atmosphere are wholesome and nutritious. If a circulation of air be afforded constantly there will be little danger of "spot," but if it should appear, promptly remove the affected fruit and burn it.

If red spider become troublesome during the ripening, it is a good plan to gather in an airy fruit room all the fruit almost ripe, or sufficiently to ripen perfectly, and then give the trees a forcible syringing, directing the water against the under side of the leaves, so as to dislodge the pests and break their webs. If clear water be used and air admitted rather freely it will not interfere with the ripening of the fruit remaining. By pursuing this treatment red spider may be kept under subjection until the fruit is gathered, when it can be destroyed by forcible syringing and the use of an insecticide. Scale should be removed with a brush and a softsoap solution or some other approved preparation.

Trees that have been cleared of the first crop require generous treatment to swell the second. Syringe twice a day to keep red spider in check, and afford liquid manure when watering is necessary. Trees in pots require liquid nourishment twice a day in hot weather, and in general once; those in borders need supplies once or twice a week, according to the vigour of the trees and the extent of the rooting area; others in restricted areas of limited extent requiring it more frequently than those in large borders. The second crop must be thinned where thickly set before the Figs are the size of pickling Walnuts, and in thinning reserve the largest fruits at the base of the shoots.

Young trees for next season's early forcing in pots must not be neglected. Afford all the light possible and keeping them as near the glass as is consistent with their growth. Syringe well and supply liquid manure, so as to secure a sturdy growth, and when that is complete they may be placed outdoors in a sunny corner to induce rest. They must not, however, be dried off, but have proper syringing and due supplies of water, and if the wood be soft the trees should be kept under glass until it is thoroughly ripened.—GROWER.

Hardy Border Flowers.

Asarums.

LOVERS of plants which are more curious than showy may direct their attention to the Asarums, although those who like bright flowers alone had better eschew their cultivation. Our native Asarum europæum, the Asarabacca, is rather pleasing because of its glossy roundish kidney-shaped leaves, and its dull brown flowers are singular in their appearance and colouring to those unacquainted with the few other species. They must be looked for, or they will remain undiscovered. An interesting species comes from Canada in the shape of *A. canadense*, which grows about the same height as *A. europæum*—i.e., about 1 foot. Its campanulate flowers are also brown, but they are even less apparent than those of the former, as they are often nearly buried in the soil. A rare species, which comes from California and is named *A. caudatum*, has never come under my notice. I understand that the lobes of the calyx are lengthened and attenuated. They are said to be brownish red in colour. Although *A. europæum* occurs in Britain it is not confined to our isles, but is found in various parts of Europe. In like manner, *A. canadense* occurs in portions of the United States. These Asarums do quite well in partial shade, and are increased by division. They do not seem to be particular as to soil.

Asclepiases.

The Asclepias or Swallow-wort deserves a little more attention from growers of border flowers, although it must be admitted that many find the few species in cultivation rather difficult to grow in the ordinary border. Of the species obtainable perhaps the best are *A. incarnata*, *A. syriaca* or *Cornuti*, and *A. tuberosa*. The last named is the finest of all. The flowers of all are in umbels, and when open produce a fine effect. *A. incarnata* is a good bee plant and is very fragrant, besides being rather pretty because of its red or purplish flowers. It grows about 2 feet high, and is a native of Canada. It will grow in a peaty or rich, light soil, and is increased by division or seeds. *A. syriaca* or *Cornuti* has pale purple flowers which have a pleasant scent like that of honey. It grows to 2 or 3 feet high, and may be cultivated similarly to *A. incarnata*.

A. tuberosa is well deserving of several attempts to naturalise it, or at least to persuade it to grow in the garden. It has very handsome umbels of bright orange flowers, and grows from 1 to 2 feet in height. It is a very showy plant, and is usually much admired when seen. It likes a deep and fairly moist soil with a little shade. There are some other species which ought to be hardy in our climate. At the time of the compilation of the Kew "Hand List of Herbaceous Plants" there were in cultivation in the Royal Gardens there the following:—*A. amplexicaulis*, *A. incarnata*, *A. obtusifolia*, *A. speciosa*, and *A. tuberosa*. Large tubers of *A. tuberosa* do not transplant well, and I am inclined to think that young plants from seeds are more easily established.

Asperulas.

Asperulas are best known in this country by the Woodruff, as *A. odorata* is commonly called. There are, however, several species which commend themselves to those interested in alpine gardens. These are beyond the scope of the present notes, and I am only acquainted with one species which can be considered suitable for the flower border. This is *A. hexaphylla*, which I have grown for several years, and can recommend as a useful plant for cutting purposes. It does not appear to be generally grown, but its white flowers may be used for some purposes where the familiar *Gypsophila paniculata* may not be desired. It grows from 18 to 36 inches in height, and has very slender stems with narrow leaves and a number of small white flowers. It is easily grown in light soil, and increases at the root with a fair degree of rapidity. It may be propagated by division or from seeds. From the latter, which can be purchased, the writer grew his plants. There appear to be two Asperulas bearing this name. One of these is synonymous with *A. cretacea*.

Asphodelines.

The Asphodelines are closely related to the Asphodels, the distinction between the two depending upon the plants under notice having erect leafy stems. The most familiar to us is *A. lutea*, commonly met with as *Asphodelus luteus*, a plant once better known than now. It was introduced from Sicily as far back as 1596, and yet remains one of the best of the genus, though some more recently introduced are very imposing and effective. It grows some 3 or 4 feet high, and has a dense straight raceme of yellow flowers and many dark green leaves lined with a lighter shade. A handsome recently introduced species is *A. imperialis*, which has reddish white flowers, and reaches a height of about 8 feet. *A. liburnica* grows to about 2 feet in height, and has yellow flowers. *A. taurica*, also called *Asphodelus tauricus*, has white flowers striped with green, and reaches about the same height as *A. liburnicus*. Other species are *A. Balansæ*, *A. capillaris*, *A. istmocarpa*, and *A. microparpus*. There is also a double flowered variety of *A. lutea*, which is a desirable plant. They thrive in any ordinary soil, and may be increased by division in spring, or by means of seed sown at that season. There is a growing taste for conspicuous plants for the purpose of adding effect to the border, and such plants as the Asphodelines will be found very desirable among others.—S. ARNOTT.

Jottings About Melon Culture.

(Concluded from page 264.)

FROM the beginning of June onward throughout the summer Melons grown in suitable houses make wonderful progress, and unless tying and stopping are regularly performed leaves and shoots soon get crowded. If at any time it is found that too many laterals have been retained, it is better to remove a few of them than to allow crowding to continue, as one firm thick leaf produced by full exposure to light is better than two weak and improperly developed ones. In order to keep the roots active a few sub-laterals should be continually trained between the main leaves or allowed to hang over the top of the trellis, or along the front of the house. This is, therefore, an additional reason why overcrowding should be avoided in the early stages of growth.

As soon as the young roots have formed a network in the soil added at the final earthing, regular feeding should be practised till the fruits begin to colour. This may be given both in the form of liquid manure and chemical fertilisers. Blood obtained from a slaughter-house diluted with six times its bulk of water, forms a splendid liquid manure for fruits of all kinds, as well as plants in pots. In country districts, however, gardeners cannot often obtain it, but they can usually procure the drainings of stables and cow sheds, which are at all times valuable for feeding plants and crops. I like to give some kind of liquid manure at every watering while the fruits are making their first swelling, for to a great extent the size of the fruit is determined during that stage.

Chemical fertilisers given in the form of a top-dressing are also of immense benefit, as they bring the roots to the surface and keep them wonderfully active, but this activity can only be maintained by regular dressings with such fertilisers till the fruit begins to change colour. If their use be discontinued earlier the plants receive a check, and the fruits sometimes do not finish well.

Some cultivators are greatly troubled with red spider, and to check it syringe their plants with a solution of softsoap, with which a little flowers of sulphur has been mixed. When this is done the edges of the leaves are often browned, as they are very tender. With a liberal feeding at the roots, due attention to watering, and syringing the plants freely during bright weather, spider ought not to give much trouble. I like to close the houses about 2 P.M. during the hottest weather, at the same time syringing every particle of foliage, and damping the floors liberally, the process to be repeated an hour after during exceptionally bright weather. Under such conditions both plants and fruits seem to advance by leaps and bounds, and revel in the "bottled" heat and moisture. Even during hot weather it is necessary to warm the hot-water pipes slightly at night, or canker and rotting at the collar of the plants will sometimes take place. A quart of clarified soot water mixed in a 3-gallon can of water is an

excellent concoction to syringe the plants with occasionally in order to promote a deep green colour in the leaves, and keep insects in check.

Occasionally one hears of black fly being troublesome in Melon houses, but it is usually caused through not keeping a sufficiently moist atmosphere during the growing stage, and fumigating is the best means of destroying the pests when they have obtained a firm footing. If only a few shoots or leaves are attacked syringing with or dipping them in tobacco water effectually prevents further trouble in that respect.

Melon plants if in good health should seldom require shading, but it is not wise to adhere to hard-and-fast rules in such matters. After long periods of dull weather if the sun suddenly shine out brightly the plants often show signs of distress, and unless shaded for a few hours may be seriously crippled, especially if carrying heavy crops. The critical time is generally when the fruits are fully grown and before they begin to colour, for they seem then to feel the strain the most. In the earlier stages of growth plants will sometimes show signs of distress through mistakes in watering, as it requires a considerable amount of judgment to know exactly when to water. With

the soil packed with roots, and plenty of healthy growth, during bright weather frequent and liberal applications are necessary, but in dry dull weather it is an easy matter to water a little too soon. The time when the cultivator must be on the alert is when a dull morning is succeeded by bright bursts of sunshine. If the promise of a dull day throughout had been fulfilled no water would have been needed, but the changed condition of the elements renders water absolutely necessary. Hundreds of plants are annually brought into a state of semi-collapse through delaying the application of water an hour too long during such trying weather.

I am no advocate for the common practice of withholding water almost entirely when the fruit is colouring, through fear of causing

FIG. 125.—SEEDLING TUBEROUS-ROOTED DOUBLE BEGONIA. (See page 460.)

them to crack, as I have practised almost every conceivable plan, and have come to the conclusion that although water is not required so often then as when rapid growth is being made, the soil should never be allowed to get dry enough to cause the plants to flag. If it does, the fruit will inevitably crack when the sap again expands the contracted tissues. It is the overdryness at the root before water is given which is the real cause of cracking in such instances, though in others too much atmospheric moisture without a free circulation of air will have a similar effect.

Some varieties, such as Hero of Lockinge and The Countess, require to hang for several days after being highly coloured before they are ripe enough to cut, and when a few fruits are slightly in advance of others on the same plant I like to cut the stems half through, just below the fruit, to lessen the supply of sap in that direction. After cutting all Melons which are not over-ripe they should be placed on a dry shelf in a warm airy house for a day before being sent to table. A Melon more than any fruit is at its best in point of flavour for a very short time, and the cultivator should learn by experience just when that stage is reached.—H. D.

Royal National Tulip Society.

May 23rd.

THE annual Southern Exhibition was held in connection with the Temple Show of the Royal Horticultural Society on May 23rd, 24th, and 25th, and never since the Southern Exhibition has been revived have better Tulips been seen. It may not be generally known, that up to seven or eight years ago florists' Tulips were practically unknown and unknown in the South of England. This state of things was not to the taste of a few northern enthusiasts, and they commenced showing in London. At first almost all the flowers were from the north, but gradually southern exhibitors have come forward, and now the position of affairs is very encouraging, and it looks as if the south will soon rival the north, both in the quantity and quality of its exhibits. The Tulip Society does not want a Tulip boom, and is content to go slowly, if surely, believing that gradual developments will bring more lasting results.

Owing to the lateness of the spring the date chosen well suited the southern growers, in fact all the flowers were grown in the south with the exception of Mr. Bentley's, which came from Llandudno. Flamed flowers were exceptionally well shown by Messrs. Hall and Chater, while on the whole Mr. Bentley had the best feathered blooms, which just enabled him to carry off the silver cup. There were no novelties of note staged, but the quality of the older varieties, such as Saml. Barlow, Sulphur, Sir Jos. Paxton, George Edward, Talisman, Annie McGregor, Bessie, Modesty, Mrs. Wood, and Trip to Stockport were very good. The following is a list of awards.

Class A. *Twelve dissimilar Tulips, two feathered and two flamed in each class.*—First, Mr. J. W. Bentley, Manchester, with Bertha and Bessie, feathered byblœmens; Trip to Stockport and Duchess of Sutherland, flamed byblœmens; Modesty and Pet, feathered roses; Annie McGregor and Mabel, flamed roses; General Grant and Masterpiece, feathered bizarres; Saml. Barlow and Lord Stanley, flamed bizarres. Second, Mr. A. Chater, Cambridge, with Adonis and Trip to Stockport, feathered byblœmens; Duchess of Sutherland and Talisman, flamed byblœmens; Annie McGregor and Aglaia, flamed roses; Annie McGregor and Sarah Headly, feathered roses; Saml. Barlow and Sulphur, flamed bizarres; Sir Joseph Paxton and Geo. Hayward, feathered bizarres. Third, Mr. A. D. Hall, Wye, Kent, with Talisman and Black Prince, feathered byblœmens; Chancellor and King of the Universe, flamed byblœmens; Miss Edwards and Comte de Vergennes, feathered roses; Annie McGregor and Aglaia, flamed roses; Dr. Hardy and Attraction, feathered bizarres; Saml. Barlow and Sir Joseph Paxton, flamed bizarres. Fourth, Mr. G. Edom, Walton, Epsom, with John Henry and Ashmole's 126, feathered byblœmens; Talisman and Duchess of Sutherland, flamed byblœmens; Mabel and Sarah Headly, feathered roses; Mabel and Rose Hill, flamed roses; Magnum Bonum and Sir J. Paxton, feathered bizarres; Dr. Hardy and Sir J. Paxton, flamed bizarres.

Class B. *Six dissimilar Tulips, one feathered and one flamed of each class.*—First, Mr. A. D. Hall, with Wm. Parkinson feathered, and George Edward flamed byblœmens; Miss Edwards feathered, and A. McGregor flamed roses; Attraction feathered, and Saml. Barlow flamed bizarres. Second, Mr. A. Chater, with John Linton feathered, and Talisman flamed byblœmens; Miss Edwards feathered, and A. McGregor flamed roses; Sir J. Paxton feathered and flamed bizarres. Third, Mr. J. W. Bentley, with Trip to Stockport feathered and flamed byblœmens; Mabel feathered, and Annie McGregor flamed roses; Saml. Barlow flamed, and Masterpiece feathered bizarres. Fourth, Mr. C. W. Needham, Hale, Cheshire, with Talisman feathered and flamed byblœmens; Annie McGregor feathered and flamed roses; Wm. Anibal feathered, and Sir Joseph Paxton flamed bizarres.

Class C. *Six dissimilar Tulips, two in each class, either feathered or flamed.*—First, Miss Scott, St. Albans, with Talisman and Maid of Orleans, byblœmens; Glory of Stapleford and A. McGregor, roses; Dr. Hutcheon and Masterpiece, bizarres.

Class D. *Three feathered Tulips, one of each class.*—First, Mr. J. W. Bentley, with Bessie, Mrs. Collier, and Masterpiece; second, Mr. A. Chater, with Adonis, Sarah Headly, and Masterpiece; third, Mr. A. D. Hall, with Prose pine, Comte de Vergennes, and Standard.

Class E. *Three flamed Tulips, one of each class.*—First, Mr. A. D. Hall, with George Edward, Annie McGregor, and Sir J. Paxton; second, Mr. A. Chater, with Duchess of Sutherland, Mabel, and Dr. Hardy; third, Mr. C. W. Needham, with Adonis, A. McGregor, and Samuel Barlow; fourth, Mr. J. W. Bentley, with Trip to Stockport, A. McGregor, and Sir J. Paxton; fifth, Mr. G. Edom, with Talisman, A. McGregor, and Sir J. Paxton.

Class F. *Six dissimilar breeder Tulips, two of each class.*—First, Mr. A. D. Hall, with Adonis, Maid of Orleans, byblœmens; Rose Hill and Mrs. Barlow, roses; Goldfinder and Sir J. Paxton, bizarres. Second, Mr. J. W. Bentley, with Ashmole's 126 and Glory of Stakehill, byblœmens; Rose Hill and A. McGregor, roses; Goldfinder and Saml. Barlow, bizarres. Third, Mr. A. Chater, with Adonis and Bridesmaid, byblœmens; Rose Hill and A. McGregor, roses; Goldfinder and Sir J. Paxton, bizarres. Fourth, Mr. G. Edom, with Adonis and Janette, byblœmens; Mabel and Lloyd's 209, roses; Excelsior and Goldfinder, bizarres.

Class G. *Three dissimilar breeder Tulips, one of each class.*—First, Mr. A. D. Hall, with Talisman, A. McGregor, and Hepworth's 100/64. Second, Mr. J. W. Bentley, with Adonis, Rose Hill, and Goldfinder. Third, Mr. A. Chater, with Maid of the Mill, Modesty, and Sir J. Paxton. Fourth, Mr. C. W. Needham, with Adonis, A. McGregor, and Goldfinder. Fifth, Mr. G. Edom, with Adonis, Rose Hill, and Richard Yates.

Class H. *Pair of Tulips, one feathered and one flamed of any class.*—Samuel Barlow Memorial prizes. First, Mr. J. W. Bentley, with Mrs. Wood, feathered; and Saml. Barlow, flamed. Second, Mr. A. Chater, with Sarah Headly, feathered; and Saml. Barlow, flamed. Third, Mr. A. D. Hall, with Guido, feathered; and Saml. Barlow, flamed. Fourth, Mr. G. Edom, with A. McGregor, feathered; and Sir J. Paxton, flamed.

Class I. *The best feathered flower in the show.*—Mr. Chater, with Trip to Stockport. The best flamed flower in the show.—Mr. Hall, with George Edward. The best breeder.—Mr. Hall, with Adonis.

Class L. *Collection of Florist Tulips, arranged for effect.*—First, Mr. Edom, with a group which included Masterpiece, Sir J. Paxton, Dr. Hardy, Mabel, A. McGregor, Talisman, Adonis, and other standard varieties.

Class H.A. *Pair of Tulips, one feathered and one flamed. For maiden growers only.*—First, Mr. W. C. Bull, Ramsgate, with Masterpiece, feathered, and Sir J. Paxton, flamed.—J. W. B.

Fruit Forcing.

Vines.—*Early Houses.*—Where Grapes are hanging afford sufficient water to the inside borders to maintain the soil in a moist condition. No injury will result to the Grapes provided the atmosphere is not stagnant, but air must be given more or less constantly. When the Vines are cleared of the ripe fruit the foliage should be cleansed of dust and red spider, employing tepid water, and, if necessary, an insecticide, as keeping the foliage clean and healthy to the last is important for aiding the formation of the buds for another season. The leaves being fresh and clean, hold the laterals in check by pinching, though should there be anything defective with the principal foliage a little freedom may be allowed to the laterals.

Houses with the Fruit Swelling.—It is not wise to dispense with fire heat, although the requisite temperature may be secured from sun heat on all but dull days and cold nights. Much, however, may be done in saving fuel by closing early in the afternoon on fine days, accompanied by plenty of atmospheric moisture. Be careful to avoid a constantly saturated atmosphere by a little ventilation at night and increasing it early in the morning. Nevertheless, a moist atmosphere is essential to the swelling of the berries, and it should be secured without stagnation by damping the floors and borders two or three times a day—in the morning, at closing time, and before nightfall. Do not allow the laterals to grow so as to crowd the principal leaves, but keep them well in hand. Where, however, there is plenty of space, they may be allowed to extend, yet not so as to necessitate their removal to a great extent later on. The temperature should be maintained at 65° at night, or a few degrees less on cold nights, 70° to 75° by day, and 80° to 85° from sun heat, allowing an advance to 90° after closing, or early in the afternoon.

House with the Grapes Ripening.—Although a constant and liberal supply of warm, rather dry air, is desirable for securing good finish and high quality in the fruit, a genial condition of the atmosphere is necessary for the benefit of the foliage. Still the air moisture must not be excessive or stagnant, or it will prejudice the ripening. Do not neglect to supply water at the roots, and if nourishment is given it should be of a sweet, not rank, nature, or the Grapes may be tainted. This often happens with late applications of soot and other organic matter. If a light mulching of short, sweet litter, be applied, it will tend to a more equable moisture at the roots. A good heat is essential to insure the highest quality. Indeed there is no comparison between Grapes that are properly finished in a rather warm and well-ventilated atmosphere and those ripened in a low temperature and moist atmosphere.

Grapes Scalding.—Muscats and other varieties completing the stoning should be carefully watched in bright hot weather, and in case of indications of scalding, air must be admitted more freely or until the colouring commences and is somewhat advanced. At that period all danger will be passed as regards the black varieties, but Muscat of Alexandria will scald when well advanced in colour, and it is necessary in houses glazed with large panes of glass to employ a slight

shading, as that of herring netting, over the roof-lights in very bright periods. While it is essential that these Grapes be otherwise well exposed to light, with Hamburg and black Grapes generally it is different. They colour best beneath a good spread of foliage, and such shade is one of the best means of preventing scalding, provided the supply of air be bountiful by day, and a little ventilation left on constantly at the upper part of the house with a genial warmth in the hot-water pipes. A temperature of 65° to 70° by artificial means suffices, or a little less for Hamburgs.

Late Grapes.—Where the Vines are in flower a constant supply of dry warm air will promote good setting of fruit, the temperature being kept at 70° to 75° by artificial heat, and rising to 80° or 90° with sun. Thin the berries freely immediately they are set. This in the case of the shy setters must be confined to the removal of the smallest and imperfect berries in the first instance, deferring the general thinning until the properly fertilised ones can be determined by their free swelling. There must not be any deficiency of moisture at the roots, therefore afford liquid manure copiously after the Grapes are thinned and swelling, or a top-dressing of some approved fertiliser, distributing it evenly over the surface and then working in moderately. If the weather be dry and the soil light, outside borders will need watering. Top-dress with fertilisers or liquid manure if the Vines are not very strong or are carrying a full crop.

Young Vines.—Those in pots for next year's fruiting should have the leading shoot or cane stopped at 8 to 9 feet, and the laterals or sub-laterals pinched at one leaf as produced. Supernumeraries in recently planted houses should also have the canes stopped at the length named, the laterals and sub-laterals being closely pinched. This will concentrate the energies of the Vines in the principal leaves and buds, and is necessary for those intended to fruit fully next season. The permanent Vines, however, may be allowed to make all the growth there is room for, but it is a mistake to encourage growth by over-stimulation and an excessively humid atmosphere. Growth should be accelerated by closing the house early on fine afternoons, admitting a little air before night, and increasing it early in the morning of fine days. When young Vines become established they will require abundance of water at the roots. Avoid, however, making the soil sodden by needless applications, and sprinkle surfaces two or three times a day so as to maintain a genial condition of the atmosphere.

The Kitchen Garden.

Tomatoes.—Sunny walls and fences are good positions for growing Tomatoes, and the sooner the plants are put out the heavier will be the crops and the greater the certainty of ripening. No very special preparation of site is needed, Tomatoes succeeding admirably in soil that will grow good crops of Potatoes. Strong young plants are best for planting. These may be disposed 15 inches apart, wherever spaces can be found between fruit trees, or against walls and fences wholly devoted to them. The soil about them should be packed somewhat firmly, and the balls of old soil and roots be kept constantly moist till such times as the roots have spread out into the new soil. Where it is not possible or convenient to plant out, large pots, or, better still, boxes, may perhaps be arranged, filling these with good soil and planting.

Tomatoes may also be successfully grown during most summers quite in the open, or without the shelter and warmth afforded by walls and fences. Sunny, sheltered borders, would naturally answer best, but they are found highly remunerative when grown by the acre and quite in the open fields. For these positions, extra early varieties such as Early Ruby, Earliest of All, Laxton's Open Air, are the most desirable. They may be put out 15 inches apart in rows 3 feet asunder, placing a 4-foot bamboo to each and attaching these to a wire strained 3 feet above the ground, or they may be planted at less regular intervals, always providing good room is afforded, and have a stout stake placed to each. If well hardened prior to planting there will be little or no need to protect from late frost.

Vegetable Marrows.—The time has also arrived for planting these on a large or small scale. Those put out earlier in May will have required much attention in the shape of protection from cold winds and frosts. Great heaps of manure are wasted on Vegetable Marrows, which not infrequently succeed better on ridges under which there is not more than 12 inches of manure, or even less. Holes 3 feet or so in diameter, or long beds 4 feet wide, may be prepared by having the top spit of soil thrown out, returning it over 18 inches or less of manure with heat and moisture left in it. When the ridges or mounds are warmed through plant either single plants or groups of three, those on the ridges being 3 feet apart. It is a good plan to alternate the ordinary trailing varieties with the bush varieties, the former eventually covering the whole of the ground, as the bush varieties are early but not continuous bearers.

Ridge Cucumbers.—Sites for these may be prepared exactly as advised in the case of Vegetable Marrows, the other cultural details being much the same. It is well to raise the plants somewhat high in the centre, as the stems are then less liable to suffer from excess of moisture, which evidently leads to canker or decay.

THE BEE-KEEPER.

Obtaining a Surplus of Comb Honey.

At this season bee-keepers are making arrangements for obtaining a surplus from their bees, and no time must be lost in deciding on the method to be adopted. In the early stages the treatment of the various stocks should be the same, namely, to have them all as strong as possible by the time the honey flow comes. Afterwards their treatment will differ. If comb honey is desired in the ordinary 1 lb. sections, all that is necessary is to place a crate of twenty-one sections on a strong colony well crowded with bees. This, however, should never be attempted unless the weather is warm, and honey is coming in freely.

For supering purposes we prefer a hive with at least ten standard frames in the brood chamber. In ordinary seasons, if the bees have received timely attention, they will be well filled with brood in various stages of development. Only a few rows of cells along the top of the frames will be filled with honey. This is always kept in reserve by the bees for feeding their young, the pollen being placed in convenient cells in various parts of the combs. Directly the bees begin to lengthen their cells near the top of the combs, which may be detected at once owing to the white appearance of the new comb, it shows that honey is coming in freely. If, however, from any cause the stock is not so strong as desired, and honey is coming in rapidly, the bees may be made to carry their honey into supers by restricting the brood nest. This is done by removing the outside frames and closing up the division board, so that the bees are compelled to remain on a few combs. The brood chamber thus becomes crowded, and the bees are forced into the super. If this is done it is not advisable to place a full crate of twenty-one sections on the hive at once, but to increase the number as required.

An early harvest of comb honey may often be obtained in this manner without any detriment to the bees. Should the weather continue fine and honey is coming in freely, frames of fully drawn out combs or foundation may be again used to enlarge the brood nest, otherwise the bees would probably swarm.

Spreading Brood.

Is it an advantage to interfere with the brood nest by spreading the brood at this season? Some bee-keepers are very successful in carrying out this operation. Others, again, fail. It should only be attempted by those who thoroughly understand the bees' requirements. We do not recommend the system, as only on special occasions do we practise it. Briefly, it is done in this manner. About every fourth day the stock is examined, and the comb next to the brood nest, in which there is probably a quantity of sealed stores, which should be uncapped. It is then placed in its former position. The honey will be at once removed and stored in various parts of the hive. This will cause the queen to commence laying freely in the cells nearest to the brood nest. The next time the combs are examined the other side of the comb is uncapped. The frame is reversed, the side containing the newly laid eggs being on the opposite side of the frame from the brood nest. This is repeated as often as necessary, and if carefully done the stock will increase at a rapid rate.

We prefer this plan to the one usually adopted of placing an empty comb in the middle of the brood nest, as the brood is much more liable to become chilled. This is the great danger, as should cold weather set in and the spreading of the brood has been overdone, it will be impossible for the bees to cover it all. It is thus destroyed, and in due course is turned out of the hive. This fact alone shows how careful bee-keepers should be in spreading brood.—AN ENGLISH BEE-KEEPER.

Gardeners' Charitable and Provident Institutions

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 175, Victoria Street, S.W.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. Brian Wynne, 8, Danes Inn, Strand, London, W.C.

• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Pear Tree Shoots with Crimson Spots (D. W. B.).—A worse infection of attack by the Pear gall mite, *Phytoptus pyri*, has not come to our notice. The creature has taken a fancy in your case to the fruit, and the young growths are also affected in the wood. Remove as much of the affected points of the shoots, the worst infested leaves, and all the fruit attacked, as it will grow deformed, but do not defoliate the tree too much, or the remedy may prove worse than the disease. This greatly weakens the tree, causing the leaves to turn brown or black and fall prematurely. Syringe the tree with a solution of bisulphide of calcium. This is made by boiling a pound each of flowers of sulphur and quicklime in a gallon of water for fifteen minutes, constantly stirring whilst boiling. Then allow to settle, and pour the clear liquid off for use. If placed in a stone bottle and tightly corked in a dark place it will keep indefinitely. Dilute with 100 parts water for use, or say a gill (quarter pint) to three gallons of water, and apply with a syringe, taking care as far as possible to wet the under side of the leaves. Repeat the syringing if necessary, but usually one application is sufficient. In the winter, whilst the buds are quite dormant, the trees should be sprayed or syringed with a solution of paraffin in seven parts of water. This treatment has been found to successfully keep the pest in check, acting well on the mites while in the scales of the buds.

Vaporisation with Sulphur for Destroying Red Spider in Vineries (R. A. C.).—1, Place the flowers of sulphur in the fumigator cup and pour on water so as to form the sulphur gradually into a paste, ultimately using enough water to cover the sulphur. Then light the lamp. When the water has been heated to 170° it commences to give off fumes. Arrange the lamp so that it does not cause excessive boiling of the mixture, and on no account allow the cup to become dry or the sulphur may burn, and give off fumes fatal to both animal and vegetable life. It is a process that requires very great care, but when the vaporiser is kept constantly at work giving off mild fumes of sulphur vapour, it has been carried out, notably by Mr. Norman at Hatfield House with good results. 2, Syringing of the Vines early in the afternoon and then shutting the house is a very old practice and good for checking the red spider. In this process the moisture generated operates well against the pest, as it delights in dry conditions at the roots of the Vines. No injury is done to the Vines if the water used be clear and soft, but in most cases the water contains so much solid matter in solution that a deposit is left on the Grapes, and this tells seriously against them for table or marketing when ripe. One of the largest growers of Grapes uses water from a hose pipe, and finds that by commencing operations when a few specks of red spider first make their appearance it is the best of all preventives and remedies. That it does not materially injure the Grapes, the fact that the bunches are disposed of in the markets at top prices testifies. Care, however, is taken not to distribute the water at random, and early steps should be taken to keep the Vines clean, so as not to have recourse to drastic wholesale syringing at a time when the Grapes are far advanced towards ripening. A house with a southern aspect closed at 1.30 p.m., and everything—"house, walls, Vines, stage, and pipes"—thoroughly wetted, is likely to generate too much heat, running up perhaps to over 100°, and the moisture may become condensed on the foliage and Grapes, causing the leaves to become scorched and the Grapes rusted. What we mean by

early closing and syringing is closing at the time in the afternoon when the sun will not raise the temperature to over 90°, or at most 95°, and then well damping the house, floor or paths, borders and walls, but not the Vines. The moisture thus generated is very inimical to the Acari, and on the other hand beneficial to the Vines. In such cases it is advisable to admit a little air before nightfall, and to cease syringing the Vines when the Grapes commence to change colour.

Twigs on Victoria Plum Tree Denuded of Buds (Loughhall).—The wood and bark of the branches and spurs are quite healthy, but on an extent of growth 18 inches in length there is not a single bud left, neither blossom nor wood; all have been removed probably by birds. On another branch about a foot long there appears only one growth from a wood bud—the terminal one of a spur. There is also one flowered growth, the incipient fruit of which has not set in consequence of being damaged by frost. We can hardly understand how the tree could have blossomed, for the sockets of the buds are quite brown, pointing to their removal some time ago. If they have been removed by bullfinches or sparrows, as we suspect, the only preventive is to trap the bullfinches or shoot them. Bullfinches and sparrows may usually be kept at bay by syringing the trees with hot limewash made thus. Quicklime is formed into a limewash consistency with water, or, what is better than water, a solution of sulphate of copper, 1 oz. to 1½ gallon of water, first slaking the lime with water into a thick paste, and then diluting it with the copper sulphate solution. It should be applied whilst the buds are quite dormant and the trees are dry, as it will adhere to them, whereas if the lime be not quite freshly burned the limewash made from such will be washed off by the first rain. As the trees are making indifferent growth we should give the ground from the stems outwards to a little further than the branches extend a top-dressing of the following mixture:—Superphosphate of lime, 12 parts or lbs.; powdered saltpetre, 7 part or lbs.; nitrate of soda, crushed fine, 9 parts or lbs.; and gypsum, ground, 9 parts or lbs.; mixed and applied at the rate of a quarter pound to the square yard. The mixture may be applied in the spring and autumn, and is one of the best applications we have used to enable the trees to overcome canker and induce a healthy growth, especially in Apple and Pear trees.

Apple Growths Mildewed (Idem).—The young shoots are affected by the Hawthorn and Apple tree powdery mildew, *Oidium farinosum*, which may be subdued by syringing or preferably spraying with sulphide of potassium or "liver of sulphur" 1 oz. to six gallons of water, repeating occasionally. When the foliage is very tender a strength of 1 oz. to nine gallons of water is safer, as the Apple, though the hardiest of British fruit trees, is more susceptible of injury from its downy foliage than many other trees. We also advise the ground to be top-dressed as advised for the Plum trees, applying the mixture without delay, so as to give some benefit in the current growth and make provision for next year's growth and crop.

Grapes with "Marks" (Cross).—The depressed marks or patches on the berries are what is known as "scalding." Some varieties are more subject to it than others, Lady Downe's being the worst, then Muscat of Alexandria, sometimes Black Hamburgh, Gros Maroc, and Alicante. It is generally caused by a confined atmosphere and the sun acting powerfully on the house before air has been admitted to induce evaporation from the berries. The berries are not usually affected at so early a stage as in the specimens, though it sometimes occurs. It is that form of scalding known as "spot," not ripening or ripe "spot," for it appears when the Grapes are young and swelling fast. It commences with a small, irregular, and whitish mark on the side of the berry, as if it had been bruised in some way. Afterwards the pulp beneath dries up and a sort of contraction occurs, the affected berry soon assuming a one-sided, irregular form. This "spot" is believed by some cultivators to be caused by sudden chills, such as having the house very close and moist, and then suddenly, on some bright morning, admitting the external cold air too freely and too abundantly. The "spot," however, is caused by the "spot" fungus, *Glaeosporium læticolor*, in not a few instances, of which the best preventive is free ventilation, especially in the early part of the day. The only remedy now is to cut out the affected berries and burn them, though the "fruits" in your case are not yet developed.

Tropæolum speciosum (W. R. Raillem).—There is often much difficulty in establishing this fine climber in places where both atmospheric and soil moisture are deficient. It thrives best in districts such as the West Highlands, where there is a heavy rainfall, combined with frequent mists. These cannot be secured elsewhere, and in drier districts it is necessary to plant the Tropæolum in a cool position, especially one where the roots and the early growths are shielded from the sun. A dry subsoil is very unfavourable to it, and we know of gardens in favourable districts where it fails because of this, though it thrives in others near where there is moisture below. In some places the great difficulty occurs in the first and second years after planting. It often makes little growth for a year or two, and then runs ahead with great rapidity. In planting we advise you to do so in a cool, shaded position facing north and east, and to water the plants frequently until the tubers have fairly taken hold of the soil and the plants have grown several feet high. Some fail from keeping the soil too open, but it ought to be made firm before and after planting the Tropæolum. It must also have something to which it can attach itself at first, such as a few twiggy branches. It does not dislike a gravelly soil provide.

it is not too dry below. Slugs are sometimes to blame for the failure, as they frequently crop the young growths as they appear. These pests like to "sample" new plants to a garden, and to this cause many have reason to attribute the loss of this exquisite plant.

Seedling Amaryllis (S. B.).—The flowers did not reach us in a proper condition for examination. We do not think, however, that the variety is distinct from others, and certainly in the state in which it arrived is rather inferior, particularly in the narrowness of the segments. We would advise your growing it thoroughly well next season, as Amaryllis, like other flowers, frequently improve immensely, and then submitting flowers to one of the leading specialists in this plant. If you wish a favourable opinion, however, you will have to adopt a better system of packing.

Compost for Peach Tree (R. M.).—An excavation 3 feet deep, parallel with the wall, and not more than half its height, is ample for a Peach border. If the soil is wet, make a drain, 3-inch tile, near the outside edge, with a proper fall and outlet, and 6 inches lower than the bottom of the border, which should incline to the drain. Place in 9 inches of rubble about the size of half bricks, then 3 inches the size of road metal, preferably old brick and mortar rubbish from a building, excluding pieces of wood and the finer particles by sifting. The surface of the drainage should be as fine as a gravel path, and covered with thin sods to prevent it being choked with soil. Substantial loam, compact but porous, is the best rooting medium, compactness being essential for the retention of the food elements, the sub-division of the roots, and porosity for the percolation of water. As the soil may not always be had according with the above conditions a good compost may be formed thus:—Take four parts of red or yellow loam, stiff and deficient in gravel or grit, one part burnt clay, one part old mortar rubbish, crushed and all pieces of wood picked out, and one part road scrapings well ameliorated. Chop the turfy loam in pieces about 2 inches square, and mix the ingredients well, placing in the border compactly when in good working order. About half a peck of wood ashes may be added to each barrowload of soil with advantage, and also a quart of crushed bones.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (T. A. J.).—1, sporeling form of *Adiantum cuneatum*; 2, *Narcissus poeticus recurvus*; 3, *Cytisus elegans*; 4, *Habrothamnus elegans*; 5, *Anemone nemorosa flore-pleno*; 6, *Muscari botryoides*. (E. C.).—1, *Prunus rosea flore-pleno*; 2, the *Alexandria Laurel*; 3, *Viburnum Gloire de Versailles*; 4, *Cryptomeria japonica*. (Subscriber).—*Asparagus Sprengeri*; *Ornithogalum umbellatum*. (H. S., Winchester).—1, *Caragana frutescens*; 2, *Choisya ternata*. (E. J. B.).—A *Viburnum*, but the specific name cannot be given unless a flower is sent. (F. J. B.).—1, *Weigela (Dier-villa) rosea*; 2, *Ulex pilosa nana*; 3, *Choisya ternata*; 4, *Halesia tetraptera* (the Snowdrop Tree).

Legislative Proposals.

MR. LONG'S Agricultural Holdings Bill having been brought before Parliament, it has been quickly followed by another proposed by Mr. Channing. Both have met with a great deal of criticism, and it is very unlikely that either will become law; in fact Mr. Channing's Bill has no chance whatever, and even Mr. Long's Government measure very little, for who knows how soon we may find Parliament dissolved?

Whereas some of Mr. Channing's proposals are so unpracticable as to be quite out of all probability of realisation at present, the chief critics of Mr. Long's Bill found their objections to it on account of its not going far enough. The Bill does seem at first sight to deal with several burning questions of tenant right in rather a tinkering manner, leaving them very nearly in their previous condition, but as long as the landlord is to have any authority or power as to the management of his property, his rights must be considered as well as the whim or convenience of the tenant.

Two of the burning questions are whether the consent of the landlord should be necessary before a tenant put up buildings or lay land down to grass. Mr. Long says yes to both.

With regard to laying land down to grass we think the tenant might be given a free hand, and no doubt few landlords would be found who would object doing so. The only case we can imagine

where a landlord would be justified in refusing permission would be in the case of an inexperienced tenant attempting to make permanent pasture of poor sand land which the landlord might prefer to plant with Larch. To meet a case like this appeal might be made to an official expert, who would decide whether the land were suitable for laying down or not. On his decision would rest the question whether the wish of the landlord or tenant be most reasonable.

Laying down grass is expensive, and it is some years before the tenant gets much benefit from it; therefore in case of a sudden termination of the tenancy—from death, for instance—the fair improved value of the new pasture should be due to him or his representatives.

The right to build without the landlord's consent is, however, a very different matter. To be able to do this with the power to exact compensation on quitting is nothing more or less than the right to spend another man's money without consulting him in any way on the matter. No doubt the argument may be used that a tenant laying down money for his own benefit would spend it wisely and for the general benefit of his holding.

That sounds very plausible, but farm tenants do not sit as long on their holdings as they once did, and as you can hardly find two farmers in the same parish who are quite agreed upon the most desirable way to construct farm buildings, every new tenant requiring alterations of some kind, if he can persuade his landlord to grant them, we might be treated to the spectacle of a landlord paying for the building done by an outgoing tenant whilst his incoming tenant requires large alterations in the same. Whilst if the landlord refuses, what is there to prevent the newcomer after he has got settled down from building himself another set in another position, or under threat of doing so compelling the owner to spend a considerable sum in alterations to premises which he had no hand in arranging, but has had to pay for?

We may be putting an extreme case, but we have seen a good deal of tenant farmers and changes of tenancy, and we are convinced that under the influence of such a law many similar ones would occur. There were great flaws in the Agricultural Holdings Act, but in trying to amend grievances it would be a great pity to institute others. We do not write as landlord partisans, having suffered personally as outgoing tenants. We had to pay full dilapidation for repairs to considerable buildings put up by our own family, and for the building of which nothing was allowed, whilst the landlord spent our money in alterations to suit the new tenant.

Another point in the Bill which has caused much discussion is the clause allowing compensation for corn consumed by horses other than those regularly worked upon the farm. We see that Yorkshire farmers as represented by the Yorkshire Union of Agricultural Clubs are in favour of extending this compensation to the food consumed by the working horses as well, and we agree with them that if one is allowed the other should be, for there cannot be much difference in the residuary value. We ourselves should prefer the manure from working horses to that from mares and foals and young growing horses consuming the same quantity of corn.

We have never set a high value on horse dung, and seeing how beneficial cattle grazing, and how detrimental horse grazing is to grass land (in some grazing districts horses are forbidden on the feeding pastures), we cannot see that agriculture as a whole is going to benefit by making outgoing allowances for horse corn. The only effect that we can see will be to make a present to sitting tenants, who will get paid when they quit for that which they got for nothing when they entered. It is only another addition to the capital sunk in tenant right, of which there is already far too much. There will certainly be nothing gained, for the alteration in the law will make no difference to the quantity of corn the working horses will get, and any large substitution of horses for cattle in English pastures is not likely to benefit either the land or the tenant.

One great improvement might be made in the Act by extending the period of unexhausted fertility of manures applied to pastures and

meadows. Of course in case of meadows manures purely nitrogenous would be excepted, and in pastures very slight extension would be advisable, but compensation for all slow-action manures should be spread over a much longer period than at present.

Another desirable addition to the Bill would be a provision to compensate the tenant for the young seeds which having been once grazed have not been ploughed up for corn, but left in a profitable condition for another year's grazing. As a system of grazing seeds two years prevails largely in England at the present time, and is likely to increase under the difficult conditions as to labour, such a very sensible addition should be sure of acceptance by Parliament if it is found possible to get a Bill through at all.

Another question mentioned at the second reading by Major Rasch is that of freedom of cultivation and sale. Such freedom is much more common nowadays than it used to be, and there is a great deal of land which could not be let on any other terms; but it would be easy to make it universal without risk to the owners of the soil by allowing dilapidation for undue drawing off of crops without proportionate return in purchased manure.

Work on the Home Farm.

At last we have a change to more summer-like weather. We have had a nice warm rain, and there really seems to be a prospect of the temperature remaining at a higher figure than we have enjoyed since last summer. We fancy there will be a good deal of spraying for Charlock this summer. The few local experiments which were made last season, though not entirely successful, were sufficiently encouraging to warrant repetition on a more extended scale.

Messrs. Strawson, who are the chief authorities on Charlock spraying, claim on the authority of a large number of farmers who have tried it that it has been a great success, that Charlock can be killed if 50 gallons 2 per cent. solution of pure sulphate of copper per acre be used. The operation should be performed when the plants are from 2 inches to 6 inches in height, and to complete the job it should be repeated in a fortnight. Early sown Turnips are coming up, and already there are complaints of fly.

Warm showery weather should prevent much damage, but where the attack is serious the following is a good device to destroy the insects:—Make a light frame long enough to stretch across five or six rows and 18 inches wide, light enough for two men to carry easily. Over this stretch old sacking or carpet, cover the upper surface of this material with gas tar, and keep the surface moist and sticky. If this frame be carried close over the rows of young Turnips the flies will rise when disturbed, a large proportion will fall on the tar and remain there, while those flying forward will be again disturbed, and few will escape.

Fortunately there is no very urgent necessity for hoeing either Wheat or spring corn, as both are clean, and in neither are there many Thistles. Still the fields must be looked over, and any stray weeds grubbed up. Even this is not easy of accomplishment, so scarce is labour of all kinds. Two or three years ago there would be in each parish gangs of men who, having been employed in draining and assisting in thrashing operations, were ready to undertake hoeing or similar urgent farm work by the piece, would make long days, thus earning good wages by overtime, and filled a most useful place in the economy of the parish. Such little coteries have almost disappeared, farmers have largely had to help each other with the thrashing, and now if corn must be hoed the horse hoe is the only kind possible.

A good horse hoe well handled is very efficient, but the grain requires careful drilling with a view to its use for really good work to be done without damage. They work well on Wheat that has been sown with a press drill after a good ploughman.

Bogus Butter Abroad.—The U.S. Consul at Bordeaux sends to the State Department the cheering intelligence (though it is really more important to the would-be consumers of butter in France than to anybody else) that the laws against selling oleomargarine for butter are now coming to be very well enforced. The French statutes are sensible and moderate, being intended merely to prevent fraud on the purchaser or eater—nothing else. They prohibit not only the offering for sale as butter of products not wholly composed of milk or cream, but make every butter-maker and butter-seller liable for having such product in his possession, however the same may be labelled. If enforced this will drive such compounds out of all groceries and markets where butter is offered. As a consequence, no dealer in oleomargarine or any similar article, whether wholesaler or retailer, can have genuine butter on the same or adjoining premises. If they deal in this product, which is not forbidden to be sold as such, it must be as a separate and independent trade. The terms of the law are wide enough to embrace hotel and restaurant keepers. Strictly construed it would, says a contemporary, effectually prevent not only dealers, but users, from having both butter and oleomargarine on their premises at the same time.

A Triumph of Hybridisation. Unique Offer.

3 NEW PASSION FLOWERS ALL DISTINCT.

Exceeding in beauty all others. Delicately
Perfumed. Free Blooming.

Raised at Oldfield Nurseries, Altrincham.

PASSIFLORA CLIBRANI.

This beautiful distinguished hybrid cannot be too highly commended. We claim it to be the ideal of all the Passion Flowers, it being a most distinct and handsome variety after the style of Princeps, but far excelling this variety. The petals are of a rich red wine colour always so attractive, rays of corona chocolate tipped with white. A charming flower in every respect. Perfectly free and vigorous.

PASSIFLORA FRAGRANT BEAUTY

As the name truly implies, this variety possesses a fragrance perhaps exceeding that of any other variety. A plant now in bloom at our Oldfield Nurseries commands the admiration of all visitors on account of the delicious perfume. The petals are pure white, rays of corona in two circles, centre chocolate brown, zoned white in the middle, upper portion bluish purple shades. Charming contrasts. Profuse bloomer.

PASSIFLORA OLDFIELD GEM.

This excellent hybrid possesses very considerable merit. It is a distinct handsome and free variety. The flowers are very large, and what has been said of the perfume of *Fragrant Beauty* we reiterate respecting this magnificent gem. The petals are pure white, delicately netted rose. The rays of the corona are in two circles, and being of a wavy outline they greatly enhance the appearance of the flowers. Centre rich velvety maroon, clear white zone, upper portion purplish violet.

Price 2/6, 3/6 & 5/- each; the set of three, 6/6, 9/- & 13/-

Apple Election.

I having occurred to me that an election of Apples would prove generally useful I addressed a circular letter to all the best authorities I could think of amongst nurserymen, market growers, and gardeners in various parts of the country, choosing as far as possible those who had practical knowledge gained by selling either fruit or trees.

The letter will speak for itself; it was as follows:—"Seeing how very desirable a thing it would be in the interests of everyone connected with fruit growing—nurserymen, fruit growers, and also the public—that the number of varieties of the various fruits should be reduced and a lead given to those of proved merit, I am getting together the views of the leading experts upon the subject of Apples."

The selections were to be made with a view to combining as far as possible quality with free bearing. All had to be essentially market Apples, but not the so-called "market Apples" whose only recommendation is appearance, for it is not with these that we can hope to hold our own against Apples from other countries.

Best six cooking Apples to be grown as standards.

Best three dessert Apples to be grown as standards.

Best twelve cooking Apples to be grown as bushes.

Best six dessert Apples to be grown as bushes.

To these letters I received thirty-two replies giving the information sought, three saying that the task was beyond the powers of the writers, and one (which ought to be sent to a museum of antiquities) in which the writer says that he has been many years collecting the information I asked for and that it was too valuable to give away, but he should be pleased to see the result of my inquiries in the Press. The italics are mine.

I take this opportunity of thanking those who gave themselves the trouble to reply to my letter,

and I trust that the information they have given may be of use to my other correspondents, as I am sure it will be to many of the reading public.

It will, I think, be wise to point out that although the replies given come from all parts of the country, the bulk of them are written from the fruit-growing districts of the south and west, so that some Apples most suitable for the north and midlands do not stand quite so forward in the list as they might have done had the votes been more evenly divided. Setting this aside, it will readily be seen that certain varieties take the lead in *all* localities, as, for instance, Lane's Prince Albert and Cox's Orange Pippin, which for bush culture have each secured thirty-one votes out of thirty-two. A remarkable feature of this election is the way such comparatively new varieties as Newton Wonder and Bramley's Seedling have come to the front; it took fifty years for Cox's Orange Pippin to gain the favour of cultivators, but things move more quickly to-day; still, I am inclined to think that such Apples as Alfriston and Beauty of Kent, which are of finest quality, and also productive, deserve more notice than they have received.

I am, of course, not responsible for my correspondents' selections, and whilst some class Blenheim Pippin as a table fruit, others call it a culinary Apple, and some of the most practical name it under both headings as a desirable variety. It is only fair to say that Worcester Pearmain would have had more votes but for my remark about quality—indeed, the votes given are recorded *despite* the quality clause. Lord Suffield and Lord Grosvenor detract the one from the other to some extent, as most growers prefer the former where it will grow, and where it will not they take the latter.

Six Standards for Cooking.

Dumelow's Seedling (Wellington)	21
Warner's King	18
Bramley's Seedling	18
Newton Wonder	17
Ecklinville	13
Lord Grosvenor	10
Lane's Prince Albert	10
Blenheim Pippin	7
Duchess of Oldenburg	6
Keswick Codlin	6
Lord Derby	6
Annie Elizabeth	6
New Northern Greening	5

Alfriston, Golden Noble, Beauty of Kent, New Hawthornden, Grenadier, and Bismarck, 4 each; others 1 and 2 each.

Three Standards for Dessert.

King of Pippins	25
Cox's Orange Pippin	21
Worcester Pearmain	14
Blenheim Pippin	11
Devonshire Quarrenden	8
Irish Peach	3

Sturmer Pippin, Allington Pippin, Duchess of Oldenburg, Ribston Pippin, and Adam's Pearmain, 2 each; others 1 each.

Twelve Bushes for Cooking.

Lane's Prince Albert	31
Stirling Castle	23
Ecklinville	22
Newton Wonder	20
Bramley's Seedling	18
Potts' Seedling	18
Lord Grosvenor	18
Warner's King	16
Grenadier	15
New Hawthornden	13
Duchess of Oldenburg	13
Lord Derby	11
Alfriston	11
Golden Noble	11
Lord Suffield	9
Frogmore Prolific	9
Dumelow's Seedling (Wellington)	9
Golden Spire	8
Peasgood's Nonesuch	7
Beauty of Kent	6

Stone's, New Northern Greening, Annie Elizabeth, Cox's Pomona, and Gascoyne's Scarlet Seedling, 5 each. Thirty others, smaller number of votes, chiefly 1 and 2 each.

Six Bushes for Table.

Cox's Orange Pippin	31
King of Pippins	23
Worcester Pearmain	20
Lady Sudeley	13
Ribston Pippin	10
Devonshire Quarrenden	9
Allington Pippin (new)	8
Claygate Pearmain	6
Irish Peach	6
Sturmer Pippin	6
Beauty of Bath	6
Mr. Gladstone	5
American Mother	4
Duchess of Oldenburg	4

Gascoyne's Scarlet Seedling, Scarlet Nonpareil, Adam's Pearmain, Blenheim Pippin, and Court Pendu Plat, three each. Twenty-eight others received one or two votes.

I regret that a goodly number of those to whom I addressed questions (twenty-four out of sixty) did not see the importance of the matter, or had not time to reply; but I think we may take it for granted that the tables given above represent the best of the knowledge obtainable in this country, and if planters take the first twelve, six, or three in each list as a guide they will not be far wrong.

As fruit salesmen have a considerable interest in the question under consideration, I addressed some twenty of the leading men in this line in all parts of the country, who handle Apples, asking them to give the twelve best cooking Apples, and six best dessert (British grown), that sold most readily and gave most satisfaction to buyers and best returns to growers. Only six replied, the others, probably dreading to disclose any trade secret, were discreetly silent.

Gooseberries.—In spite of the lateness of the season there were plenty of good sized Gooseberries in the shops and markets for the making of Whitsun tarts, and the mad ones of the earth may participate in the suitable refreshment of Gooseberry Fool. How cheap the berries are, too, telling most forcibly of their abundance! Lancashire Lad, Keepsake, Industry, and Crown Bob are the prime producers of early green berries, and amongst the most profitable of varieties; I may, perhaps, say the most profitable of fruits, for with good bushes and a good crop of berries, few fruits return more profit per acre than do Gooseberries. No one can say that the consumer is wise in so partaking of the fruit, because in its half developed stage it contains little that is nutritious; but to the consumer that matter gives little concern, and certainly it gives none to the grower.—D.

Odontoglossum Rolfeæ optimum.

IN our last issue we illustrated and described a superb *Odontoglossum* from one of the leading continental growers. We now bring to the notice of our readers *Odontoglossum Rolfeæ optimum* (fig. 126), which was exhibited at the Temple Show by Mons Ch. Vuylsteke, Loochristy, Ghent, Belgium; it was recommended for a first-class certificate by the Orchid Committee of the Royal Horticultural Society. It is a singularly handsome flower, and was the centre of a considerable amount of attention from Orchid enthusiasts, amongst whom there was a diversity of opinion as to whether *crispum* or *Pescatorei* had been associated with *Harryanum* in its production. The sepals and petals are white, save for a flush of rose at the tips, and numerous spots and blotches of chocolate colour. The front portion of the splendid lip is pure white.

Cymbidium l'Ansoni.

THE number of new *Cymbidiums* that are shown at the various exhibitions of the Royal Horticultural Society is not great, and very few indeed are known by the special recognition of the Orchid Committee. On the occasion of the recent Temple Show, however, Messrs. H. Low and Co., Bush Hill Park Nurseries, received an award of merit for *Cymbidium l'Ansoni*. This plant, of which an excellent representation is given in fig. 127, is said to be a natural hybrid, of which even the supposed parentage was not stated. The flower is large, and has pale green sepals and petals; each organ has reddish brown bars, which become more pronounced towards the base. The lip is milk white, with a brown tinge on the front portion.

Miltonia vexillaria.

Notwithstanding all that has been written respecting this lovely Orchid, there are still many growers who fail to grow it well for any length of time. It is certainly one of the finest species in cultivation, and there

forms particularly, such as the unique *M. v. Memoria J. D. Owen* for instance, but take a group of it with good forms, and it is sure to command a lot of attention.

Referring again to the Temple, there was more than one expert in Orchid culture who was surprised at the amount of flower produced by the plants from the establishment over which M. Linden used to preside. Looking at the plants one would not say certainly that they were out of health, but in fact many plants have been shown from English nurseries with far better growth. And again, it was to be noticed that many of the plants were by no means well potted; the base of the pseudo-bulbs was too far from the surface of the compost, and in consequence the roots were exposed.

Yet the flowers were lovely, and this proves plainly enough that it is not always the largest, most plethoric pseudo-bulbs that produce

FIG. 127.—CYMBIDIUM l'ANSONI.

the best flowers. It is well known, too, that overfed ill-ripened growth is much more likely to be attacked by thrips, and eventually spotted, than that which is reasonably strong and moderately hard. One of the most successful growers of *Miltonia vexillaria* in this country told me that when rare and unique forms come into his hands for propagation he never felt the least compunction about cutting them up even to single bulbs, but after doing so he always placed them in pans for suspending near the glass, and used moss only for compost.

Bad peat has more to answer for in regard to killing Orchids of rather fastidious taste than any other material, and certainly, unless it can be obtained of good lasting quality, it is better to leave it entirely out of the compost for weakly growers, depending upon the moisture-holding and sweetening properties of the springy sphagnum, adding only sufficient charcoal or crocks to keep the bulk open and prevent it settling down closely. The advantage of shallow rather than deep pots will be evident to anyone acquainted with the habit of the roots of *M. vexillaria*.

Regarding the time for repotting, this does not differ from the majority of Orchids. I have on many occasions pointed out in the *Journal of Horticulture* that the time least likely to inconvenience the plants is just at the time when new roots are issuing from the newly formed growth, and this is true of the species under notice. The young roots have the advantage of entering the fresh sweet compost, and thus assist in this case in swelling up the new growths and producing the flower spikes.

The temperature necessary for *M. vexillaria* has long been a vexed question among growers, some holding that a low and very moist one is necessary owing to the plants being so likely to be attacked by thrips in a house kept warmer. There is a certain amount of truth in this, but with the advent of XL All and other safe and effective insecticides, it is the cultivator's own fault if he lets his plants be badly infested. A happy medium here hits the mark best; a house kept lower than the *Cattleya* house with ample atmospheric moisture and light.

FIG. 126.—ODONTOGLOSSUM ROLFEE OPTIMUM.

was no other plant so much admired among the Orchids at the recent show at the Temple. And I do not mean the very rarest

Lælia purpurata Backhousiana.

Forms of this lovely *Lælia* with flushed sepals and petals are not rare by any means, but in this fine form it is very deep in colour and regularly distributed. Unlike *L. p. Ashworthiana* that was shown a few years ago, it has not at all the appearance of a monstrosity. This latter has the appearance of carrying three lips. In contour, and in size, too, *L. p. Backhousiana* leaves nothing to be desired, and it is evidently free-flowering. It would make a fine companion plant to *L. p. Littleiana*, figured in last week's *Journal of Horticulture*.

Kergerstenia graminea.

Although a small and not a particularly showy Orchid, this is a striking and brightly tinted species well worthy a place in collections of a representative character. The foliage is narrow and grass-like, the blossoms occurring from the base on single-flowered peduncles, but as these are freely produced the effect of a well flowered plant is very good. Like other dwarf species it must not be overpotted, and as thrips are fond of the young foliage see that the atmosphere is always kept moist. Being a native of New Grenada, it does not need much heat.—H. R. R.

The Parson's Freehold.

Now, I do not want to draw down on my poor head vials of wrath from every parson in Great Britain. I speak of the few, and the shortcomings of those few do not extend to their ordinary duties and responsibilities. In matters spiritual they are wide awake, and are ready with many a lesson and excellent precept. It is on the outside of their churches where I think that their vigilance slumbers. It is astonishing, when one considers how often they pass through the churchyard, that they cannot see how miserably neglected it looks. So many of our village churches are set in excellent positions—their architecture, though perhaps not of the first order, is fairly good; the fabric is kept in repair; and more than that, there may be embellishments of stained glass and carved oaken work. Several places will occur to the reader where all that could be done has been done to render the House of God seemly and orderly. But who cannot recall cases where the churchyard—our last resting place—is most obviously neglected? The grass has in course of time grown rank and ugly, for it is only by constant cutting that beautiful turf is made. Not only is the grass bad, but unsightly weeds of all kinds have reared their heads. The principal path may be kept fairly in order, but there is a look of unkemptness everywhere. Some churchyards have been levelled, so as to make the grass easier to manage; that takes away from the picturesqueness, and is not altogether desirable.

There are plenty of churchyards with the old raised mounds that are kept in perfect order, so the thing can be done. The secret lies in the wardens and vicar working harmoniously together. It is not done without expense, but in most villages there can be found old men who for a small wage will gladly potter about with shears, and keep things neat and tidy. People naturally want to visit the graves of their friends, but it does not look well to allow of beaten tracks; a croquet hoop or two will divert the traffic, and hurt no one's feelings. Pleasant is that yard when the stately trees abound; but if there be trees, there is a want of turf where they throw their shadows and spread their roots. This difficulty may be got over by the use of Ivy; there are so many beautiful varieties, and they grow quickly if well planted. One grave I knew where the rough stone crosses were recumbent, husband and wife laid side by side, and now round and about each stone the glossy leaves make a beautiful framework. No matter how dense the trees, the Ivy will grow and will look well at all seasons.

It is possible to make the turf attractive. Violets, white and purple, will grow almost anywhere, and what can be lovelier than a carpet of them? The first of the season are always under the south and east walls, and beauties they are. Some long dead hand in the same yard set lavishly Crocus bulbs, and more recently Daffodils have found their home there. Round the foot of several graves the harbinger of spring, the Snowdrop, raises her pure head, and the saucy Aconite is irrepressible. At one corner someone planted on a young girl's grave a little white Scotch Rose. The friends are all gone, the tree remains. A few Irish Yews may look stiff, but they are stately, and the crimson berries in autumn and early winter make grand points of colour.

The grass never comes quite up to walls of the sacred edifice. A gardening vicar will not wait for his wardens, but will take off a nice piece of grass and turn the ground into a pretty border. Against the buttress I would have some climbing Roses—the evergreen variety, the common Cluster Roses. Dean Hole recommends for this purpose

Félicité Perpetué; I add Ruga and Dundee Rambler,² they are all quick growers, and do not die out as some of the grander Roses would do. Over a porch I know is Honeysuckle, and below the east window is trained Clematis Jackmani and a small shrub bearing crimson berries, which I believe is called Cotoneaster. At the base there are big plants of Christmas Rose, and they are sheltered and preserved clean by huge fronds of common Fern, which at the first frost falling make a capital covering. At the chancel door is the yellow summer flowering Jasmine, and the border is filled with all manner of sweet and pleasant plants. A few "Geraniums" look well against the grey stone and green background, but a lover of beauty needs no hints. Under the north wall little else will grow except Ferns, but they are so graceful in themselves that nothing more is needed.

Unless the architecture of the tower is too good to allow of it, nothing looks so well as Ivy. There is one old Norman church not far away where, the east window being uncoloured glass, Ivy makes the most delightful tracery. A few modest Primroses should lurk in unsuspected corners; in fact, they may be put everywhere where not too hot. The large ox-eyed Daisies flourish well in some places. I have seen them covering children's graves. If a start is given by the vicar he will soon see his efforts well seconded by his people. All might be asked to contribute to the border, for the fuller it is the better it looks, and some of the tall perennials make a handsome show. The big June Lilies must not be forgotten—so pure, so white, so sweet. If natural flowers are found in a churchyard those unsightly china wreaths will vanish as if by magic—the contrast will be too great. There is nothing like educating the taste—false notions of beauty (?) will disappear.

I would make the graveyard speak of life and hope and immortality. Let it be the beauty spot of the village. Death should come as a friend, not an enemy. Ostentatious show is not what we look for, but great beauty may reign around, and the poor sorrowing heart may feel soothed and lightened by the sweet influences that pervade the hallowed place.—THE MISSUS.

A Dearth of Peaches.

THE markets of Britain are usually fully—sometimes too fully—supplied with the various descriptions of fruit in their season, for have we not the whole world to draw our supplies from, and, in some respects, to compete with, which makes the task of profitable fruit growing at times no easy matter. This season Plums of splendid quality have been largely sent us from the Cape, and after their journey of 6000 or 7000 miles, have reached the metropolis in good condition, and many of them have from thence been despatched to the principal towns throughout the country, where they seem to find a ready sale. I do not know definitely what has been done in regard to the supply of Peaches from the same source, but apparently they are not sent in large quantities, or do not stand the journey well, for it is an undoubted fact that the supply of good Peaches is not equal to the demand. This remark not only applies to the early part of the summer, but also truthfully indicates the state of affairs onward till the end of September. High-class fruiterers in the north and midlands are often at their wits' end to know how to get Peaches at short notice. Quite recently I had some conversation with a fruiterer who does a very large trade, and he stated emphatically his difficulty with Peaches was not selling, but getting them, although he was always prepared to pay the price asked by any grower. This has been his experience during the last two or three seasons.

When the outdoor crops are ripe I expect the difficulty in obtaining this luscious fruit is not so great in the south as in the north and midlands, where few are grown in the open air; but it seems to me to open up a good field for enterprise among southern growers, for as soon as the London markets are overstocked with any kind of produce, some of it is quickly despatched to large provincial towns. A still better system of distribution would be for large growers to communicate direct to fruiterers in various parts of the country, and thus save the many intermediate charges which often play such havoc with the grower's returns. I feel sure that British horticulturists are too enterprising to allow this annual scarcity of Peaches to long continue, but those who are first in the field with an adequate supply will, as of old, reap the greatest reward.

Let me now turn to the practical side of the matter, and advance a few ideas as to the best means of producing crops at various seasons. The earliest crop might with advantage be grown in pots, because when the fruit is gathered the trees can be set in the open air, and

the house planted with Tomatoes, and these would be cleared soon enough for filling the house with Chrysanthemums. When early crops are produced from trees planted out, the house is too long empty during the best months of the year to render it as profitable as it should be.

Crops which ripen at the end of June and during July need little fire heat, and the most profitable way of growing them is in large, wide span-roofed houses, or in wide three-quarter spans erected on a sharp sloping bank. In either instance the ordinary precise methods of training should be abandoned. After the trees are planted out in good soil, either the natural soil trenched, or a border specially prepared, the shoots would need a certain amount of shortening back for a couple of years to secure an evenly balanced tree, and should then be allowed to grow on the extension system, simply thinning out the shoots to admit light. A row of short standard trees planted in

in which late crops were grown in the south of England, but further north it would be necessary to pay more attention to training and keeping the shoots thinly disposed in order to secure well ripened wood. Of course houses already in existence could be turned to account for Peach growing, and the orthodox method, training the trees to a trellis fixed to the roof, would in such instances answer admirably; but when houses are specially built for the purpose that method of training is not, in my opinion, the wisest one to adopt from a commercial point of view.

Large quantities might also be grown in the open air by utilising vacant spaces on walls, buildings, and fences having south or south-west aspects; an east aspect is not often suitable for Peaches except in very warm localities, as the cold winds of spring blister the leaves so badly, and the risk from frost when the trees are in blossom is great. In all instances a coping board and canvas, or a

Photo by Mr. G. R. King,

Cardiff.

FIG. 128.—THE TERRACES AND LAKES, ST. FAGAN'S. (See page 485.)

the centre of a span-roofed structure would in time fill the whole available space, but supernumerary trees trained in pyramidal shape ought to be planted around the sides. These could be kept within bounds by periodical root-pruning, and when necessary removed altogether. Trees grown in the above way produce immense quantities of fruit, and seem to succeed as well as Apple trees do in the open air, with this advantage—viz., that a crop may be secured with unfailing regularity each year. In dealing with a hip-roofed house the trees should be planted at the back and loosely trained to a strong trellis erected over the border; this trellis ought to be at least 3 feet from the glass for the convenience of fastening the fruit, as well as for the benefit of the trees, which thrive well and are so easily kept free from insects when kept at a good distance from the roof. In wide houses a row of trees could also be grown along the front and trained to a semi-circular trellis.

The above methods would also be suitable for unheated houses

double thickness of fish netting, ought to be regularly used as a protection from frost at night while the trees are in bloom. If strong, healthy, transplanted trees were procured to start with, and the extension method of training adopted, walls 10 feet in height could be quickly covered, and if the results over a series of years were noted the return would well repay the labour and expense entailed.

Let it be clearly understood that I do not suggest that either walls or fences should be built for the purpose, but that the greatest advantage should be made of those which exist, and that in many instances shelter worn-out or worthless trees, which do not produce fruit enough to pay for the labour of pruning and training. If an outlay can be made in building, let it be expended on glass houses, whether heated or not, as there is then a sure return for the expense involved, as the production of a crop is within the control of the cultivator.—H. D.

The History of the Rose.

THAT the Rose was known to the Israelites, and is mentioned in the Old Testament, there can be little doubt. It was probably known to them by the pre-eminent title *chabalzeleth*, for, although that may have been the general name for a flower, yet, like the Persian *gul*, it may have been applied to the Rose as the flower—the superlative of the floral world. *Rosa spinosissima* and another species is a native of Palestine; but as we have no description of the flower in the Old Testament, whether these or some other flower is intended remains quite uncertain, though some flowers mentioned in its pages are translated into “Rose” in our authorised version.

When we descend to later ages, when descriptions of the flower were given, we cannot but be struck by the almost unvarying name of the flower. In Greek it is *Rhodon*; in German, *Rose*; in Dutch, *Roos*; in Danish, *Rose*; in Swedish, *Ros*; in French, *Rose*; in Italian, *Rosa*; in Spanish, *Rosal*; in Portuguese, *Roseira*; in Russian, *Rosa*; in Polish, *Roza*; in Bohemian, *Ruze*; in Slavonic, *Ruxiza*; in Finnish, *Ruus*; in Welch, *Rhos*; in Anglo-Saxon, *Rose*; and in Gaelic, *Ros*. Everyone of these seems to be derived from a root-word signifying red or ruddy.

The Rose is mentioned by Homer and by Anacreon. By the former in the hymn to Ceres, by the latter in many of his odes, through which we learn that it was a flower remarkable for the beauty of its petals; that it grew amidst thorns; that it had a divine fragrance; was of the colour of the human complexion; that it was the most beautiful of all flowers; “the queen of flowers;” the “flower of love.”

Theophrastus and Pliny state that Roses may be distinguished one from another by the roughness, smoothness, colour, smell, and the greater or smaller number of their flower-leaves or petals. The latter writer, speaking of the Rose generally, thus describes it:—“The Rose grows upon a thorny rather than on an herbaceous plant; it grows also upon a plant similar to a Bramble. There it has an agreeable smell, but not perceptible at any great distance. The whole flower sprouts at first enclosed in a calyx full of seeds, which in a short time swells, and becomes pointed at the summit like green alabaster.* By degrees the flower grows, opens, and expands itself, containing in the middle of its calyx the erect yellow stamina.” This author then proceeds to enumerate eleven kinds of Roses, which, he says, were well known to the Romans. They are the following:—

- | | |
|-----------------------------|----------------------------|
| 1. <i>Rosa Prænestina</i> . | 7. <i>R. centifolia</i> . |
| 2. <i>R. Campana</i> . | 8. <i>R. græca</i> . |
| 3. <i>R. Milesia</i> . | 9. <i>R. græcula</i> . |
| 4. <i>R. Trachinia</i> . | 10. <i>R. moscheuton</i> . |
| 5. <i>R. Alabandica</i> . | 11. <i>R. coroneola</i> . |
| 6. <i>R. spineola</i> . | |

Four other kinds of Roses are mentioned by Pliny in different parts of his “Natural History,” but of these he gives no description; they do not appear to have been in such high repute as the above, though somewhat esteemed for their medicinal properties. These kinds are called *R. alba*, *pallida*, *spinosa*, and *quinquefolia*.

Of the first two kinds of the eleven more particularly described by Pliny, the Campanian was the earliest in flower, and the Prænestine the first which ceased blowing. The Milesian was of a very bright colour, and consisted of not more than twelve petals; it was the latest which came into blossom. The Trachinian Rose was less red than the Milesian. The colour of the petals of the Alabandic Rose inclined to white; it was less esteemed than any of the preceding. The *Rosa spineola* had a large number of very small petals, and was the least esteemed of all. The *Rosa centifolia*, or Hundred-leaved Rose, had many small petals. It grew in Campania in Italy, and in Greece near Philippi; to the latter place, however, Pliny says it was not indigenous. It grew also in the vicinity of Mons Pangæus, and the neighbouring inhabitants, taking it from this place, cultivated it for profit. The Rose called *græca* by the Romans, but by the Greeks *Lychnis*, had only five petals; it was of the size of a Violet, and grew only in moist situations; it was scentless. The petals of the *Rosa græcula*, which were very broad, were rolled or convoluted into a ball; they did not expand, except when forced by the hand, and had the appearance of always growing. The *Rosa moscheuton* had petals shaped like an Olive, and grew upon a stem like that of the Mallow. (“*Funditur e caule malvaceo*.”) The *Rosa coroneola* was an autumnal Rose, and, when compared with other kinds of Roses, had a flower of a middle size. All of the above-mentioned Roses, according to Pliny, were destitute of fragrance, with the exception of the *R. coroneola*. The Prænestine and Campanian Roses obtained their names from their respective localities. The Trachinian Rose appears to have been a native of Thessaly, and grew near the city of Heraclea, called also

Trachinea. The Milesian and Alabandic Roses were probably foreign kinds, the former deriving its appellation from Miletus, a city in the Island of Crete, where it was first found; the latter from Alabanda, a city of Caria, in Asia Minor.

Mentzelius in his “Lexicon Plantarum,” regards the Prænestine, Trachinian, and Milesian as varieties of what he calls the *Rosa rubra saccharina*, which he considers the same as the *R. græcula* of Pliny. Mentzelius and Clusius both agree in calling the Milesian Rose the Rose de Provence. Ferrarius, in his work entitled “*Flora, seu de Florum Cultura*,” states that the Rose called by him “*Rosa alba multiplex*” has by different authors, been regarded as either the *Rosa spineola*, *Campana*, or *Alabandica* of Pliny. He says, also, that some authors consider the *Rosa damascena multiplex* to be the same as the *Rosa coroneola*, while others, again, think it is the *Rosa spineola* mentioned by Pliny.

The flower enumerated among the Roses by Pliny, and which was called by the Romans *R. græca*, but by the Greeks *Lychnis*, is the flower mentioned by Dioscorides under the name *Lychnis stephanomantike*, or *Lychnis coronaria*. It is generally considered to have been a species of our present genus *Lychnis*, commonly known as the Rose Campion. Dioscorides says the “*Lychnis stephanomantike* is a flower resembling the white Violet, but of a purple colour.” It was woven into crowns, hence called *stephanomantike*, or *coronaria*.

There is one other Rose mentioned by Pliny, but not classed by him with the kinds most celebrated among the Romans—namely, the *Rosa sylvestris*. This Rose, called also *Cynorhodon* by Pliny, and by Scribonius Largus *R. canina*, grew upon a Briar, according to the former author, and had a leaf resembling the impress of a man’s foot. Theophrastus, who also mentions this Rose, says it bore fruit of a red colour. Dioscorides agrees with this account, and says the fruit resembles the nucleus of an Olive. Pliny, however, states that this plant bears a black berry, which, Bodæus a Stapel remarks, no other author has mentioned, and considers that the passage in Pliny refers to another plant subsequently mentioned by that author. Among the thorns of the stem of the *Rosa sylvestris* grew a round sponge-like substance resembling a Chestnut; the presence of this excrescence upon this kind of Rose is also mentioned by Marcellus, an old writer on materia medica. Pliny says it grew particularly upon the *Cynorhodon*, and that it contained a worm or grub which produced the insects called cantharides. The same insects are mentioned by Aristotle to issue from a worm found upon the *kynakanthe*, or “Dog-briar” (?) In the spongy substance alluded to we recognise the moss-like prickly excrescences which are found upon all Rose trees; but especially upon the *Rosa canina*, and which are the habitations of the insect called *Cynips rosæ*.

Commentators on Pliny regard the *R. sylvestris* of this author to be the *R. Eglanteria* of Linnæus, now the *R. rubiginosa*, which, according to Fries, Linnæus for a long time referred to the species *R. canina*. The *Cynorhodon* of Theophrastus, the *Cynosbaton* and *oxyacantha* of Dioscorides, the *cynacantha* of Aristotle, and the *R. sylvestris*, *cynorhodon*, *cynosbaton*, *cynapanxim*, and *neurospaston* of Pliny have been generally considered as identical. There still appear, however, to have been some doubts upon this point which are not yet satisfactorily explained. It would be uselessly occupying space to enter at length upon the consideration of this question. The *R. sylvestris* appears to have obtained its synonym *R. canina* or *cynorhodon* from a supposition that its root was a beneficial remedy for bites of mad dogs; an instance of its curative powers is cited by Pliny.

The Roses mentioned by Theophrastus are four only—viz., 1, *Rhodon pentaphylla* (five-leaved); 2, *R. dodekaphylla* (twelve-leaved); 3, *R. eikosaphylla* (twenty-leaved); 4, *R. ekatontaphylla* (hundred-leaved).

The first of these is considered by Stackhouse to have been the same as the *Rosa canina* of Linnæus;* the second has not been referred to any species with which we are at present acquainted; the third is thought to resemble the *R. cinnamomea*; and of the fourth, or Hundred-leaved Rose, Theophrastus says, “The inner petals are exceedingly small, for the blossoming is such that some are inward and some outward. The greater number of such,” he adds, “are about Philippi.”

Theophrastus gives no detailed account of the Roses he has named; he merely says that they are not large, and have not a pleasant smell. He enumerates the Rose tree among perennial and woody shrubs, also among those plants which have their fruit placed under their flowers, “a peculiarity,” he remarks, “which, on account of its great size, is most plainly to be seen in this plant.” Some classical writers, who have endeavoured to show that the odes of Anacreon which eulogise the Rose are frauds, have gone so far as to say that Theophrastus never saw a Rose, and support this opinion from the very cursory manner in which he notices the plant. It is impossible, however, to coincide with them.

* The “alabastrus” was a perfume-box which the Rose-bud resembled in form.

* Illustrationes Theophrasti, &c. Auctore J. Stackhouse. Oxon, 1711.

Hybrid Streptocarpus.

ONE can name few, if any, florists' flower upon which the grower has not exercised his skill during the past twenty years. By the aid of hybridisation and cross fertilisation the forward movements have been numerous and singularly advantageous. When we look at the Chinese Primulas, Cyclamens, Gloxinias, Chrysanthemums, Roses, and others, we see that while one or two in each may have been with us for from twelve to twenty years, the great majority are of modern production. The craze is apparently for novelty, and naturally enough the skilled hybridist does his best to satisfy the general demand.

As far as hybrid Streptocarpus are concerned, we must come down to within seven or eight years before we find them being operated upon in earnest. Prior to that the range of colouration provided by the species was comparatively limited, though what we had were very distinct the one from the other. As with the flowers so with the foliage, which presented marked characteristics. Here, then, was a new field, and one of the first to venture on it was the firm of J. Veitch and Sons of Chelsea, who, seeing the commercial popularity of a hybrid race, urged Mr. John Heal to practise his hand. The work was soon under weigh, and at the present moment we are feeling the beneficial results, for the advance made has been most extraordinary. Where six years back there was a limited selection of colours, and in some cases ungainly foliage, we now have an abundance of shades from which to choose, and the plants are, moreover, of attractive habit.

The section known as Veitch's hybrids has become immensely popular by reason of the varied colours provided in the flowers, the ease with which they may be grown, and their remarkable floriferousness. Of course some people do not succeed in their culture; but this is the case with all kinds of plants. So far as can be gathered, however, the chief cause of failure is the provision of too much heat. The seedlings should be raised in a warm temperature, but during all the subsequent stages a greenhouse is the most suitable place that can be found for them. In a greater heat the plants are subject to attacks from insect pests, notably mealy bug, and the peculiar formation of the leaves makes their eradication almost impossible. Thus the plants soon commence to suffer, and the results attained to are frequently the reverse of satisfactory. But when the plants are treated on more rational lines, as is the case at the Feltham Nurseries of Messrs. Veitch and Sons, one may look in vain for insect pests; they are absolutely kept at bay by good cultivation. The spectacle presented by a house 100 feet long full of splendidly flowered plants will be readily imagined by those persons who saw the collection at the Temple Show.

The strain now in all justice termed Veitch's New Hybrids continues to make material advance, and never prior to this year have the plants been so good. It is very apparent from their condition that they are similar to most other plants in preferring a purer air in which to make their growth to the tainted atmosphere of the metropolis. The flowers are clearer in colour, and with the leaves

have greater substance. Amongst the diverse colours we find crimson, crimson purple, purple, rose, flesh, purple violet, pink, pure white, white with purple blotches, and white with rose blotches. As indicative of their floriferousness it may be added that on one footstalk were counted as many as nine perfectly developed flowers. As each plant produces several spikes one can readily picture the effect of a good collection.

As an advance upon this section we now have Streptocarpus achimeniflorus, which was obtained by fertilising *S. polyanthus*, a pretty South African species having bluish purple flowers, with a white form of one of the firm's original hybrids. This has resulted in a plant of splendid habit, hardy constitution, and even greater freedom of flowering than the hybrids. The photographic illustration of *S. a. albus* (fig. 129), and which was lent by Messrs. Veitch & Sons, gives an admirable idea of the habit of the plant, but the flowers are shown far too small. One can scarcely grasp from the illustration the breadth of the flowers, or of the great length of tube which add so

greatly to its beauty. Subsequent to this a type with larger flowers has been secured, and this is named *S. a. giganteus*. These give blooms of mauve, Cambridge blue, and lavender shades. There are plenty of Streptocarpus at Chelsea now, and those who wish to see them may do so at practically any time.—F. W. H.

[An award of merit was recommended for this strain by the Floral Committee of the Royal Horticultural Society on Tuesday.]

FIG. 129.—STREPTOCARPUS ACHIMENIFLORUS ALBUS.

Notes on Flea Life

A FRIEND of mine was remarking lately that he thought gardeners often had more annoyance from fleas than many people; the idea seemed laughable, but it is possible he was right. In such a matter we cannot expect to get any statistics which would give conclusive evidence. It is a fact, however, that gardeners have often to do with matting and sundry woollen substances, which are presumed to be nurseries for the flea tribe;

also some of them keep tools and other appliances in wooden sheds not of recent construction, and these are supposed sometimes to harbour fleas. Again, dog kennels are frequently placed in a yard near to the garden, and they afford home for the insects, both in the juvenile and adult stage. Though the dog flea may prefer to take its aliment from the quadruped, I consider there is no doubt upon the point that both this species, and the one infesting cats, will attack mankind when they have the chance.

As an entomologist I am obliged to own that the history of the flea is lamentably meagre, and we have not been able to ascertain yet some most important particulars concerning its habits. Thus, for instance, we do not know whether there is only a yearly brood or a succession. There are certain months when they appear to be more numerous, or active at least; these are in the spring and autumn. The erratic habits of *Pulex irritans* afford one excuse for this, and the undesirableness of much acquaintance with it is another. A philosopher who has studied the character of the flea remarks that it exhibits a singular combination of deep cunning and reckless hardihood, which is probably near the

truth. There is a good deal said now about the conveyance of disease germs by flies, mosquitoes, and other insects, but I do not think that the flea is a sinner in that way; there seems to be little likelihood of germs attaching themselves to its horny body. It would be unpleasant to think this possible, since the flea of the street vagrant can transfer itself to the person of a passing lord. Quite bad enough, however, are the effects; in some individuals repeated punctures made by the flea actually set up a sort of fever, which rather suggests that this insect must, like the gnat tribe, inject a poisonous fluid after it has pierced the skin.

Many folks are surprised when they are told that the flea commences life as a slender footless grub, which at maturity spins a cocoon, from which, in due course, the leaping insect emerges. Very little notice has been attracted by this grub, because it does not seem to be a blood-sucker, and lives where it is not likely to be looked for, or, if sought, discovered, owing to its minute size. Evidently, one of the places which would be likely to yield it is the hair of some animal that is infested by fleas. A lady, says one entomologist, was nursing her favourite dog, and afterwards found in her lap a host of tiny objects, which on examination were ascertained to be flea eggs. This explanation may account for the early life of some of the fleas that belong to various animals, but it hardly helps us to clear up the history of our particular flea, possibly the larva or grub might live amongst the clothes of dirty people. Mats, rugs, carpets, hassocks are believed to be the principal abodes of flea grubs. Churches are too often made by these insects their headquarters, the grubs living on the cushions, matting, or hassocks, and then as fleas attaching themselves to, and departing with, the visitors or worshippers. Miss Ormerod relates an instance that came under her observation, where, on the periodical removal and beating of hassocks in a churchyard, armies of fleas were seen travelling in all directions, showing that they are favourite resorts of the insect.

It is impossible to accept the theory, for such it only can be, that the old fleas feed the young ones by disgorging blood which they have themselves sucked. In fact, the notion is ridiculous, and the fate of the juveniles would be bad indeed, when the wandering habits of the flea are taken into account, supposing they did depend on parental attention. A flea that is in London some morning may travel with somebody hundreds of miles before night. Again, some have suggested the flea grub may prey upon various mites or Acari, which, no doubt, do commonly occur upon the materials where the insect is reared. The insect was allotted a place in Miss Ormerod's annual report upon insects for 1898, and I think we may accept her opinion on this subject. She believes that with their trenchant jaws the flea grubs bite up and thrive upon the dry substances they live amongst, their food being solid, while that of the adult is liquid. Of course she does not assert this about fleas in general, though it may be true, but speaks as to *Pulex irritans* in particular. The fact is not unimportant, since there are lurking-places of the flea grub which are exposed to atmospheric influences, and their growth is favoured by dry weather. Hence, after the hot, dry summers of 1898, 99, adult fleas were very abundant and troublesome. Possibly, but I throw this out as a conjecture, the moist weather of last February may be the cause of a less number of fleas than usual this spring in some districts. That fleas deposit eggs in the spring is certain, and that brood of grubs is said to feed up rapidly, but there may be also a winter brood, produced by eggs deposited during the autumn.

Miss Ormerod gives instances reported to her of the sudden appearance of fleas in such numbers as to amount almost to a plague. Thus the village of Haslington was found to be swarming with them. "cottages, fields, a large farmhouse (the inmates of which were scrupulously clean, indoors as well as out), really in colonies, not only the poor, but the better class of people being troubled; all ordinary means to get rid of them proved of no success." This lady advises a research for the grubs whenever that can be done, and the washing of articles they may haunt with hot soapsuds. Those things which cannot be washed might be sprayed with benzine.—ENTOMOLOGIST.

The Tea Crop in India.—The tea out-turn for the month of May in the Assam and Sylhet and the Terai districts was normal, in the Duars and Darjeeling poor, while in Cachar both the out-turn and prospects are good. In Darjeeling the immediate prospects of the crop are fair. In some portions of the Assam district the leaf is backward owing to the generally unfavourable weather which prevails.

Notes on Ferns.

Maidenhair.

To have *Adiantum cuneatum* in good condition for cutting the plants must not be grown in a close atmosphere, or the fronds fade almost directly they are removed from the plants. Those started in brisk heat early in the season should have pushed freely, and may now be prepared by placing in a cooler temperature. If the plants are gradually hardened to this treatment they will not only solidify the fronds already made, but they will continue producing them, which in their turn will be ready for cutting. Thus a succession of fronds will be maintained for a long time. During the whole of the summer months this *Adiantum* should not be subjected to too much heat, for it is not required; on the contrary, the plants do much better in an intermediate structure. My most useful plants for the late summer and autumn were started in heat, and then grown in a cool house until the fronds were used. It is a good plan to divide into two or three plants that have had the fronds used from them and are too large for 5 or 6-inch pots, and place a portion at this season of the year in wire baskets 7 or 8 inches in diameter, growing them at the back of a vinery suspended so that they can be reached from the path when they require water. The plants really do better when grown on this principle than when in pots, and yield abundance of fronds for cutting. Sporeling plants required in a very small state in thumb pots for decoration must not be grown in too much heat, or their fronds become weakly and their beauty is destroyed.

Davallias.

These are amongst the most useful of Ferns for cutting, and such varieties as *D. bullata*, *D. elegans*, *D. canariensis*, *D. dissecta*, and others thrive much better in small baskets the same as advised for *Adiantums* than they do in pots. While making their growth these plants enjoy the moist heat of a vinery, and the cooler treatment afterwards also suits them admirably, hardening their fronds for cutting. Although these varieties grow remarkably well under comparatively cool treatment, they nevertheless produce more than three times the number of fronds when grown in heat. *D. dissecta* is deciduous during the winter, but it is no worse for this, as it starts freely into growth directly it is introduced into heat. Plants that were started three or four months ago have abundance of fronds, and a few weeks' cool treatment will render them durable when cut. The fronds of these Ferns when well hardened are amongst the very best that can be grown for packing to travel a long distance.

Microlepia hirta cristata.

This a charming Fern for decorative purposes in 4 or 6-inch pots singly in vases, or even in the centre of the dinner table. From a large plant it is not difficult to cut a number of small pieces. These soon establish themselves in small pots in heat, and should then be grown in a vinery or an intermediate structure, potting them as they require more root room, for if grown in too warm a temperature they become a prey to scale, and fail to produce their beautiful crested fronds. Young plants started now will be symmetrical specimens, if not crowded together, for use during the autumn and winter.

Polystichum proliferum.

Where small Ferns are required for associating with other plants for room embellishment, this should be raised in large numbers. It is one of the most serviceable plants that can be grown, will give less trouble in preparation than probably any other variety, and is easily increased. The old fronds should be pegged upon the surface of light soil, and young plants are produced the whole length of the fronds. When these are sufficiently large and well rooted the fronds should be cut off, the young plants lifted and transplanted into pans singly until they are large enough for 2-inch pots, which is the case in a very short time if kept in a vinery or warm moist structure. For many purposes of decoration the plants need not be potted, but lifted from the boxes when required. If larger plants are necessary those that have done duty can be transferred into 4 and 5-inch pots, or be planted outside, for this Fern is perfectly hardy.

Selaginella Kraussiana.

Probably this is the most useful species that can be grown for covering the surface of pots and for all other decorative purposes for which such plants are required. Plants in shallow pans, small pots, and boxes should be prepared at intervals of two to three weeks, according to the demand. When used for the surface of pots and other similar purposes I have found it to last decidedly best when established in shallow pans, so that the roots and a portion of soil can be removed with the plants. A sufficient stock of established plants should always be kept on hand and thoroughly hardened in a cold house some weeks previous to being used. It is a good plan to establish a stock on the surface of Vine or Peach borders, or other similar positions, in a little light sandy soil ready for filling pots and pans as required.—F. L.

NOTES & NOTICES

Recent Weather in London.—June was ushered in with cold rain and boisterous winds. On Saturday little rain fell in the metropolis, but it continued very dull and cold until the afternoon, when the sun shone for a brief space. On Whitsunday it was fine and much milder. Bank Holiday was brilliantly fine and very warm, with a pleasant breeze, and holiday makers turned out in great force. Tuesday, too, was fine, as also was Wednesday.

Rawtenstall Park.—The premiums of £50, £30, and £20, offered by the committee appointed to lay out the proposed park and playground at Oak Hill for the best plans have, we learn, just been awarded. Each plan was to entail a cost of not exceeding £4000, including the cost of materials, clerk of works, commission, and other expenses. The first prize was gained by Mr. E. Thomas, designer and contractor, Aughton, near Ormskirk; and Mr. David Bird, architect, Atlantic Chambers, Manchester. Second, Messrs. W. Barron & Son, Borrowash, Derby; and third, Messrs. Hinnell & Murphy, engineers and surveyors, Bolton.

Fruit for London.—London has been specially favoured recently with a large and cheaper supply of fresh fruits than has ever been known. About 25,000 cases of Australasian Apples are in the hands of dealers. French Cherries are coming in large quantities, and some of them, sound and well coloured, are being sold as low as 3d. a pound. Green Gooseberries of English growth have been sent to market in ton lots, and have sold at 2d. a pound. A further shipment of fresh Mangoes has arrived from the East, and new Gros Maroc Grapes have sold at 6s. a pound. Belgium has shipped large quantities of forced Grapes. From the Canaries the week's supply of bunches of Bananas came to 20,000.

Wicken Fen to be Preserved.—Naturalists, especially botanists and ornithologists, will be pleased to hear that the last remaining piece of wild fenland in the fen district, which has been marked down for reclamation for some time past, is, after all, to be preserved in its wild state. This last remnant of the great swamp, Wicken Fen, has been a paradise to the student of those forms of life that only flourish among such surroundings. It owes its preservation to the fact that the National Trust for the preservation of places of national interest has secured a small holding in it, and a number of enthusiastic natural scientists have also bought up bits of the place. A number of our rarer birds, insects, and plants find their last refuge there, having been driven by drainage and cultivation out of the huge areas over which they were formerly spread.—("Westminster Gazette.")

Bristol Gardeners' Association.—The opening meeting of the summer session was held at St. John's Parish Room on Thursday, May 31st. Mr. G. Brook presided over a large attendance. Mr. W. J. Hockey of Yatton was the lecturer, his subject being "The Kitchen Gardener and what is Expected of Him." In a clear and concise manner he described the most suitable position for a vegetable garden, the soils best fitted for vegetable culture, with the proper methods of treating it, advocating good drainage, trenching, effectual manuring, and an abundant supply of water laid on. With regard to manuring, he insisted strongly on the advantage of some knowledge of chemistry to gardeners, especially in the use of chemical manures. He also advised all to keep a complete diary of operations for reference as well as comparison of one season's results with another. He claimed for kitchen gardening that it was the highest point in the gardener's operations, and urged the constant endeavour to secure the best possible results. A short discussion followed, and Mr. Hockey was heartily thanked for his attendance and lecture. Prizes were offered for three Cabbages and a brace of Cucumbers, that for the former being secured by Messrs. Ross and Binfield, the latter by Messrs. Hutton and Marshall. Certificates of merit were awarded Messrs. Ross and Shaddick each for a *Cypripedium barbatum*, Mr. Thoday for Carnation and Gloxinia, and Mr. McCulloch for a collection of Zonal Pelargonium blooms. A feature of the exhibits was a collection of several varieties of Lilac blooms shown by Mr. E. Poole, F.R.H.S., gardener to Lady Cave, Cleve Hill, Downend.

Gardening Appointment.—Mr. H. R. Richards, for some years gardener to Col. Trafford Rawson, Coldham Hall, Bury St. Edmunds, has been appointed head gardener and estate superintendent to Lady Ella Russell of Chorley Wood House, Rickmansworth, Herts, and enters upon his duties on August 12th.

Charlock-spraying Demonstration.—A successful demonstration of Charlock-spraying was carried out at Luton, Beds, in May. A week previously about half an acre of ground, thickly covered with a crop of Charlock, had been sprayed with a solution of copper sulphate. At the same time portions of this plot were kept covered during the operation of spraying, so as not to be touched by the solution. On the day of the demonstration this plot presented a curious appearance, and afforded an excellent example of the effects of spraying with copper sulphate. The whole area was bare ground, except for the portions covered during the spraying, where the Charlock was still growing luxuriantly. The Bedfordshire Chamber of Agriculture has appointed a committee to watch the progress and report the results of these experiments.

The Tree Monger.—One of the quaintest, prettiest old-world spots near the metropolis, and one that has many historic associations, is in the market. This is Whitton Park, Twickenham, originally the residence of that Duke of Argyll, who was dubbed by Horace Walpole the "tree monger." The Duke laid out the grounds in most sumptuous style, amongst the statuary being the famous Highland Piper and Dog, in marble, by Gabriel Cibber, the identical piece of sculpture upon which De Foe penned his grotesque story of the dead cart in his "History of the Plague." The Duke planted the fine trees upon the estate in 1724, and whatever Walpole's contempt for him, deserves the thanks of the nation for his services to forestry and the introduction of many fine foreign trees and ornamental shrubs into landscape gardening. Amongst others who have resided at Whitton Park in later days was Sir Thomas Chambers, R.A.

Brockwell Park.—At its meeting on Tuesday, 29th ult., the Parks Committee of the London County Council recommended a contribution of £30,000 towards enlarging Brockwell Park. The proposal was the purchase of 43½ acres of land lying to the north of the park, and bounded on the east by Dulwich Road, on the north by Water Lane, and on the west by Brailsford Road and the strip of park forming the Brixton entrance. Part of the property was in hand and part was sub-let. Roughly about one-half would be immediately available for the public use. The land was situated in a part of London which was being rapidly covered with houses, and was, indeed, one of the few remaining pieces of land within the four-mile radius from Charing Cross which could be utilised for open space purposes, unless the Council should adopt the very costly alternative of purchasing property and clearing it for the purpose. It was for the most part suitable for cricket and other outdoor games, and on its acquisition a great deal of it could immediately be brought into use for that purpose. This scheme would require Parliamentary sanction, and, subject to that, the Council agreed to the recommendation.

The Devon and Exeter Gardeners' Association.—The committee have much pleasure in announcing that they, by permission received from the gentlemen named, have been able to make arrangements for another of those pleasant and profitable excursions on the lines followed so successfully in past years, and it is hoped that the members, honorary members, and friends may join this excursion in good numbers, so that it may be as great a success as those which have preceded it. A generally-expressed wish that our annual excursion this year should be to the eastern portion of the county—towards the borders of Dorset—weighed with the committee in adopting this circular trip. The party will leave Queen Street Station on Wednesday, July 11th, by the 9.15 train for Axminster, reaching there at 10.18. At 11 o'clock we proceed in brakes to Lyme Regis, where luncheon will be served. At 1.30 we shall resume the journey and proceed to Pinhay, the seat of Wilton Allhusen, Esq. After inspecting the gardens and grounds there we proceed to Rousdon, the seat of Sir Cuthbert Peek, Bart., where, in addition to the interesting gardens and grounds, the remarkable and historical landslip will be inspected—interesting geologically and in many other ways. From the landslip a half-hour's walk will bring us into Seaton, where a substantial meat tea will be served at 5.30. The return journey will be made from Seaton at 9.35. Fare, inclusive of all charges, members 7s. 6d., friends (non-members) 10s. Tickets must be taken not later than Friday, 6th July.—ANDREW HOPE, Hon. Secretary.

The Linnean Society.—At a recent meeting of this society the Hon. C. Ellis exhibited photographs of a *Taxodium distichum*, growing at Oaxaca, in Mexico, and of another gigantic tree, a native of Cambodia. The circumference of the former, at a height of 3 feet from the ground, was stated to be 143 feet, while the height was estimated to be not more than 100 feet. The native name for this tree is Sabino.

Gardeners and Floral Decorations.—At a meeting of the Leeds Paxton Society, on Saturday, Mr. John Turton, gardener to Mr. Schreiber of Becca Hall, gave an interesting lecture on "Room Decorations." He pointed out the necessity of so arranging and massing flowers and foliage plants that they shall harmonise with their surroundings, and he gave many useful hints as to methods and designs to get the best effects with flowers and Ferns with a view to blending with various shades of tapestry. Afterwards, Mr. Turton answered a number of practical questions, and was accorded a hearty vote of thanks.

Royal Meteorological Society.—At the invitation of the president of the Royal Meteorological Society a meeting was held at the rooms of the society on Thursday afternoon, the 31st ult., to consider the question of a memorial of the late Mr. G. J. Symons, F.R.S., the distinguished meteorologist and founder of the British Rainfall Organisation. It was resolved unanimously that the memorial should take the form of a gold medal, to be awarded from time to time by the council of the Royal Meteorological Society for distinguished work in connection with meteorological science. The meeting appointed an executive committee, representing many of the societies with which Mr. Symons was associated, to take the necessary steps to raise a fund for that purpose. Contributions will be received by the assistant secretary, Mr. W. Marriott, 70, Victoria Street, Westminster.

National Rose Society.—A special general meeting of the National Rose Society was held on Tuesday last at the Horticultural Club, Hotel Windsor, for the purpose of electing an honorary treasurer in succession to the late Mr. T. B. Haywood. Dr. Maxwell T. Masters occupied the chair, and there were about a score of members present, including Mr. Ed. Mawley, one of the honorary secretaries. The notice convening the meeting having been read, Mr. Mawley referred briefly to the loss the society had sustained in the death of their late admirable treasurer, and further stated that he had ascertained that Mr. Charles Burt Haywood, son of Mr. T. B. Haywood, had consented to fill the office until the close of the year. It having been proposed, seconded, and carried unanimously, that Mr. C. B. Haywood be elected treasurer for the remainder of the year, the special meeting was brought to a close. It is hoped that the new treasurer may be induced to continue to undertake the duties for an unlimited period, as his late respected father by his business aptitude brought the society's affairs into an excellent state, which the son could maintain.

The Oak, the Ash, and the Weather.—Whether the Oak or the Ash is first out depends on the soil on which each happens to stand—whether warm gravel or cold clay; also upon the more sheltered position. The proverb is about as scientific as the countryman's saying:—

"A Saturday moon
And a Sunday full
Never was noa good
And never will."

JOSEPH BLOMFIELD (in the "Daily Mail.")

¶ The saying should read:—

When the Oak is out before the Ash,
Then 'twill be but a little splash;
When the Ash is out before the Oak,
Then the summer will be a soak.

The Oak was a month behind the Ash in the years 1816, 1817, 1821, 1823, 1828, 1829, 1830, 1838, 1840, 1845, 1850, and 1859, and all the autumns were unfavourable and the summers wet. On the other hand, the Oak was in full leaf many weeks before the Ash in 1818, 1819, 1820, 1822, 1824, 1825, 1826, 1827, 1833, 1834, 1835, 1836, 1837, 1842, 1846, 1854, 1868, and 1869, when the summers were hot and dry, and the harvests good. In the remaining years the two trees came into leaf at practically the same time, and the seasons were decidedly average ones.

—C. W. BROWN (in the "Daily Mail").

June Prospects.—June "the womanhood of May," although it made a bad beginning, usually has a promise of better things, and we look for 179 hours of bright sunshine and a considerable increase of temperature. The mean temperature for June averages 60°, while the highest reading we have had since 1871 was 91° in 1878, and the lowest 35° in 1880. The average rainfall for the month in London is 2 inches.

May Weather at Hodsock Priory, Worksop, Notts.—Mean temperature, 50.1°; maximum in screen, 70.7° on the 17th; minimum in screen, 30.6° on the 11th; minimum on grass, 23.0° on the 17th. Number of frosts in shade, two; on grass, thirteen. Sunshine, 113 hours, or 23 per cent. of possible duration. Difference from average - 0.61. Rainfall, 1.72 inch; difference from average - 0.64. Rain fell on ten days; maximum fall, 0.86 on the 8th. Rain from January 1st, 10.38 inches; difference from average + 1.17. A dull but dry month, with a good deal of N.E. wind and very little warm weather.—J. MALLENDER.

May Weather at Dowlais.—Rainfall 3.27 inches, which fell on fourteen days; greatest fall 0.96 inch on the 21st; for the same period 1899 4.30 inches. Temperatures: mean maximum, 57.87°; highest reading 71° on the 18th; mean maximum 36.032°; lowest reading 28° on the 17th; below freezing point on eight nights. Sun temperature: mean 65.903°; highest reading 88° on the 18th. Sunless days ten. The prevailing direction of the wind was N.E. A month remarkable for the bitter cold, strong winds experienced, and the very high day temperatures on the 16th and two following days; and the night temperatures 31°, 28°, and 29° respectively.—WM. MABBOTT.

A Cold May.—"Changeable, cheerless, and chilly" expresses the type of weather we have had during the month of May. The mean day readings, as well as the night readings, were below the average, and on the 10th the thermometer in the screen registered 32° both at Brussels and Loughborough, and only 34° at Oxford. Frost occurred on four nights between the 13th and 19th, and on the 16th, at Loughborough, the reading of the exposed thermometer was as low as 25°. The highest reading during the month in London was 71° on the 27th. The rain god was so busy distributing 5 inches of rain at Blacksod Point that his duty to the metropolis was forgotten, and we had a deficit of over an inch of rain during the month, and fifty-five hours too few of bright sunshine.

The Weather.—Ugh, here's weather for the first of June—cold, wild, wet, wretched! These are adjectives enough, but all needed to fully describe the condition of things meteorological on this the first of leafy Juno. Well, the month is leafy enough—it is gloriously leafy, and when the temperature is pleasanter the trees are beautiful to look upon. But what pleasure is there in doing so when a cold north-easter is blowing, and a very cold rain is falling? Certainly, we needed the rain, but we needed warmth more, and we have got instead of summer bread, winter stone. Surely the summer with its genial warmth and especially soft balmy nights will come some time, but when? We rejoice when we escape very severe cold spells in the winter, but what a penalty we have to pay for such mildness in the long, cold, cheerless springs, and summers that very rarely begin until we have reached the traditional midsummer!—A. D.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

A remarkably dull week; some days quite sunless. Small quantities of rain fell on two days.

The Poisonous Sumach.

SINCE writing to you we have found out that it is the *Rhus Toxicodendron* that causes the skin irritation. Would you mind making it known amongst your numerous readers that this, although a beautiful and quick growing creeper, is decidedly injurious to have upon a dwelling house? Last Tuesday I cut away a few shoots; on Wednesday my face and arms began to swell, and on Friday I was unable to see out of my eyes. As I stated last week, my mistress has had several severe attacks, and could not make out which creeper caused it. Now we know for certain. —F. CROOK.

[This letter refers to a query on page 494 relating to the action of *Rhus* leaves supposed to be *Ampelopsis*. There are two kinds of poisonous Sumach, *Rhus Toxicodendron*, known in the U.S.A. as "Poison Ivy" or "Poison Oak," and *Rhus venenata*, known as "Poison Elder" or "Poison Dogwood." The former is very common in California and in the neighbourhood of San Francisco, where country picnics and excursions are a popular form of dissipation, it causes much inconvenience and fright. On some constitutions the effect is very severe, though we have never heard of a case that has had a fatal ending. Innocent excursionists often unwittingly decorate themselves with this pretty but baneful Sumach.]

Seminal Varieties of Trees.

EVERY year paragraphs appear in the newspapers relative to the leafing of the Oak and Ash, and the "splash" or drought that is portended, according as one or the other of those trees wins the race in the development of foliage. We are told in a note on page 459, last week, that "the Oak was the first to leaf this year, which indicates a dry hot summer and a bountiful harvest, just as in 1898." Does this imply that the leafing of the same trees was in different order in 1899? I venture to assert there was no difference between them in priority of leafage in that or any year.

I have noticed that Oak trees as a rule, and speaking generically, always develop leaves before the Ash trees do that are growing near them. But there are exceptions. Some few Ash trees always precede certain Oak trees in leafing, but this denotes nothing as to the weather that will follow, but is simply a question of variety or seedling variation. Trees of both genera that are raised from seeds differ in stature and contour, as well as in precocity in leafage. It is precisely the same with Horse Chestnuts.

I can every day see a splendid avenue of the last named trees—some hundreds of them; and very beautiful most of these trees have been during the past three weeks, but not all. Though they were taken from the same seed bed, and were of exactly the same size when planted, they differ strikingly now, both in size, shape, and the character of their flowers, while some always have developed, and always will develop, leaves sooner than the others, simply because some are in their nature early and others late. For half a century a particular Ash tree has been noted as the latest in leafing of all trees in a large parish, while a particular Chestnut is far in advance of all its congeners in assuming its spring and early summer garb.

An avenue of Lime trees, no doubt raised from seeds, is most uneven, and altogether disappointing, while another avenue from grafted trees is entirely uniform and beautiful. The variations in Ash and Oak trees, are not, as a rule, so markedly diverse, yet the differences are plain enough, some being naturally late and others early in leafing. An early Ash precedes a late Oak, but the overwhelming majority of the Ash trees are the later year by year. So much for the Oak and the Ash and the splash. That the early or late leafage of one or the other of those trees is just a case of seminal variation is the opinion of—A NORTHERN GARDENER.

OLD traditions die hard. I had thought the old story about the Oak and the Ash leafing was about dead, but I see it is still lively. I should like to ask of any close observer of nature if they ever saw the common Ash in leaf before the common Oak. The old quatrain begins "when the Oak's before the Ash." There is great virtue in that "when," just as we often find in an "if." I have observed these trees closely for many years, and have found the Ash to precede the Oak in leafing. That being so, is it worth while to prognosticate the nature of the weather? because that has happened which always happens, let the season be a wet or dry one. Some Ash trees are earlier than others, as some Oaks are, but in the Ash florescence is early and prominent, and may often be taken for leafage by partial observers.—OBSERVER.

A New Kew.

REMEMBERING how during the discussion which has recently arisen over the proposed new Chiswick, the exceeding salubrity, healthfulness, and beauty of Kew Gardens has been quoted, I was a good deal surprised when an influential municipal friend here in conversation the other day mentioned a conversation he had had with a very high municipal person of Richmond, who intimated that because of the difficulty experienced in growing certain things at Kew it was contemplated to remove the gardens to a less populated district. I fear I smiled over that intimation, for it would need all the queen's horses and all the queen's men to take Kew as it is to pieces, carry it twenty miles into the country, and put it together again. Still farther, I had not heard of those distressing conditions of culture existing at Kew, of which there has been so much reason to complain in smoke-ridden Chiswick. Possibly the Richmond official was labouring under an attack of Kew fever, which had distorted objects so much.

But what was a respected contemporary driving at last week when he said, "Kew was thirsty, and at the present rate of things the gardens were likely to suffer as they did last summer from 'draught.'" No doubt we have here a nice printer's error, the unfortunate "comp." at the moment being in a draught, or perhaps being "drought" wanted a "draught." I hope no one has any hard things to say of Kew, because it had suffered so far this season from lack of rain, but some persons may gladly seize on the suggestion conveyed that not only is Chiswick, through excess of drainage being soil dried, but that Kew Gardens is sharing the same fate. Must even the gardens authorities, as they look upon the flowing Thames, yet exclaim, "Water, water in plenty, yet not a drop for our lawns and trees!" Surely it is not quite so bad as that.—KINGSTON.

A National Victoria Rose Day.

I do not see the least reason for concern that we have few Roses to wear on St. George's Day. What have English people to do with a personage who may or may not have existed, and concerning whom those who profess to know do not write in complimentary terms? Let us bury such personages in proper oblivion. It was I who, in one of our Surrey papers, made the proposal that if England wanted a national Rose day, it should be on June 28th, the anniversary of the Queen's coronation. That was written in answer to a local complaint, that Roses could not be had on April 23rd. Well, it is folly, of course, to be proposing flower days at seasons when flowers cannot be had. Primrose people were wise in selecting a flower for their purpose on April 19th, that was everywhere in season and abundant.

If we really want a national Rose day, common sense tells us to select a day when Roses are plentiful. To suggest as a Rose day a date when only wealthy people can purchase flowers is ridiculous. On June 28th we are in the very thick of the Rose season, when everybody can have, and if they like, wear a flower, and if the day be known as the "Victoria Rose Day," in honour of the Queen, and of her wondrous reign, it would probably endure. That English people are lacking in the needful emotional feeling to make them enthusiastic over a proposal of this kind I am aware. They like Saint Barleycorn better than all the Saints of the Calendar, and King Gold they love to distraction, whilst all other kings and queens have from them very temporary admiration. Whilst I should like to see a national Rose day, and everybody wearing a flower on June 28th, I have little anticipation that it will be generally respected. When Britons declare with somewhat isolated bumpiness that they are not as other nations are, one can but regret that in many respects it is true. We have not all the virtues.—A. D.

New and Rare Plants.

THE numbers of new or rare plants, and of those that have been to all intents and purposes lost from the view of general cultivators, and which have been brought before the Floral Committee of the Royal Horticultural Society of late years, are very considerable. Bearing this fact in mind, and further having regard to the great educational value of the society's fortnightly meetings, it strikes me as deplorable that the practice of giving all possible information respecting the plants shown should have fallen into disuse. There was a time when a grower sent with his plant every item he knew that dealt with its history and parentage, and these facts proved of the utmost value from an educational point of view to the visiting public. When one sees at a show a plant, on the table set apart for the rarities, that particularly excites one's admiration, one naturally wants to have all the procurable information respecting it. This is provided in the most readily available form on cards attached to the individual exhibits.

As an example of my meaning, I may mention *Schizanthus Wisetonensis*, which was exhibited at the Temple Show. Notwithstanding the fact that it was entered for special recognition, and in fact received an award of merit, so far as I could ascertain not an iota of information was forthcoming for the edification of the committee. From my point of view this was one of the finest plants in the entire exhibition,

and I sought diligently for particulars, but beyond the palpable fact that it was a *Schizanthus*, nothing could be gleaned.

Cannot something be done to remedy this state of affairs? It is clearly against the wishes of the Royal Horticultural Society, for we find on page 50 of the society's "Arrangements" for the current year, the following:—"The name of the fruit, flower, plant, or vegetable, and in the case of seedlings particulars of parentage and date of raising, should be given if possible. If an importation the name of its native country should be added. Exhibitors are invited to communicate, *in writing*, such further details of the origin, history, introduction, or peculiarities of their exhibits as they may think interesting. . . ."

I venture to think that almost the whole of the information sought in the above notes could be provided in many cases, and I think that all readers of the *Journal of Horticulture* will be at one with me when I assert that the interest of the exhibits would be increased fiftyfold by its being inscribed on cards attached to each exhibit. I should, however, like to read the opinions of other frequenters of the R.H.S. meetings on the subject. I may say that my remarks have particular reference to the exhibits placed before the Floral Committee; both the Orchid and the Fruit and Vegetable Committees are far better served in this particular respect.—F. J. B.

The Royal Horticultural Society—Looking Both Ways.

"SCRUTATOR," on page 460, has some significant remarks as affecting the present status and the future prospects of the Royal Horticultural Society. He traces the present prosperity of the society and its ever growing strength and influence to the policy of the council. It would be difficult to attribute it to anything else. What has been the policy so steadily pursued? It has been one having for its objects the advancement and exemplification of horticulture in its different phases; or in other words, a true gardening policy, adopted and pursued as far and as well as its means allowed.

This, as many, or most, old friends of the society well know, has not always been the case. There has been at least one deplorable departure from a sound line of action. This was known as the South Kensington policy—a policy of gewgaws and glitters that brought the once prosperous society to the dust. It was against such policy that the late Dr. Hogg and other good men and true fought so strenuously; and after the crash came sought with assiduous effort to rehabilitate the old society again. Others followed with the same commendable object in view, and the present flourishing state of the society shows with what success.

Is it to be supposed that the present directorate, under whose management the society has made such gratifying progress, would take any steps in the least likely to jeopardise its fame and bring about their own ignominy? The idea is preposterous. The council, as a body, is essentially conservative—too much so, some people have thought—and the last men that could be thought of to indulge in any fanciful or sentimental speculation. They are practical business men, and do not act without serious thought and anxious deliberation. Having, as "Scrutator" suggests, the worst national garden in Europe, they evidently consider the time has arrived for providing a garden worthy of the kingdom, and with the time have come the means for carrying out the object.

This policy—this truly horticultural policy—is opposed, the lead not being taken by horticulturists as a body, but in its more active form by scientists. They want no new garden for the exemplification of horticulture, but denounce its cost while advocating the erection of a grand hall in London that would cost about ten times more than a garden, the hall to be occupied once a fortnight, and bring practically nothing in commensurate with the outlay involved.

Is history going to repeat itself, and the welfare, or even existence, of the society risked in pursuance of a London show policy, in contradistinction to a policy of national scientific and practical horticulture? The Temple Shows are successful because they occur just once a year. With many shows of magnitude the fickle public appetite would pall, interest slacken, the shows dwindle, as they did—first at Chiswick, then at South Kensington, and later in the Regent's Park. What, then, would be the society's asset? Just a grandiloquent hall—a costly white elephant.

The best gardening in Europe and the finest of gardens are found in Great Britain. The love and the practice of gardening is spreading far and wide. The Royal Horticultural Society is perhaps the foremost of its kind in the world. It and the great gardening community are as much entitled to a garden worthy of themselves and the country, for the practical demonstration of true horticulture in its varied phases and useful aspects, as the botanical part of the community is entitled to the grand establishment of Kew. We are all proud of Kew, and wish to see it flourish. No one grudges its cost, though great; and it would lose none of its characteristics and charms by the establishment of a great national garden and school of industrial and commercial horticulture, that would command support and benefit the nation. Why should not this be provided? Turn out a council willing and able to provide it, in favour of a London policy, and what then? A mere London local society, with a life worth perhaps ten years' purchase, or a return to the conflicts of the past.—AN OLD FELLOW.

St. Fagan's Castle.

A Foreword.

FOR upwards of half a century the pages of the *Journal of Horticulture* have been adorned at frequent intervals with illustrations of the various beautiful estates in different parts of the country; but so far as the present writer can ascertain, the gardens and grounds of St. Fagan's Castle have received no recognition. This must perforce be ascribed to the remissness of contributors in that corner of South Wales, as in variety of interest, from a gardening point of view, it is one of the richest in the entire principality. There are others of broader acres, which contain features that St. Fagan's has not; but this does not alter the fact that its omission from the *Journal* pages is a dereliction of duty that cannot be put right too soon. It is not a place of modern creation, but counts its history by hundreds of years, as the architecture of the mansion—it can scarcely be termed a castle—amply demonstrates. It is, as may be seen in the illustration (fig. 130) of Elizabethan character, and has grand old stone walls with mock embrasures, that may or may not have seen actual warfare. It is said that one of the last serious battles of the Cromwellian era was fought within sight of St. Fagan's—in fact, that the Royalist officers made their headquarters at the castle ere they succumbed to or escaped from the doughty Roundheads. But while so much of historical tradition clusters round St. Fagan's, it has also a present day interest attaching to it, for Lord and Lady Windsor take a keen delight in horticulture. Both are in a sense enthusiasts, and favour any scheme that contains promise of enhancing the beauty of their estate.

The Dutch Garden.

To all intents and purposes the expression Dutch garden spells formality. The mind instinctively associates with it the dwarf clipped hedges, the orthodox shrubs, and, though perhaps inclining rather to the Italianesque, the statuary. There are all these at St. Fagan's, and more, for here steps in the influence of Lady Windsor, whose predilections do not lie with the customary bedding plants. Instead therefore of the "Geraniums," the *Calceolarias*, and similar things, we find those of a freer habit of growth, and which produce, generally speaking, fragrant flowers during the months of July, August, and September. Stocks are particularly in request, and one can easily imagine what a delightful picture is made by the many branched plants producing spikes of sweet scented crimson, purple, white, and scarlet flowers. These, while retaining an element of shapeliness, have not the geometrical precision of growth that characterises the habit of the plants customarily employed in such positions. The clipped shrubs observable in the illustration, and the small amount of statuary, justify the retention of the title of the Dutch garden.

The Mulberry Grove.

In the left foreground of the same picture may be seen a number of trees the majority of which are Mulberries. These give an air of antiquity to this home garden, for the older specimens must have passed the summers and winters of more than 300 years. They spread their great branches and growths over a considerable area of ground, and yearly bring forth an abundance of the much appreciated fruits. To many visitors this small garden would be one of the most interesting on the estate. All the trees are not of one age, several being much younger, they having been planted with a view to forming a veritable Mulberry grove. One might almost weave a story on the lines of "Looking Forward," and speculate therein as to what the Castle of St. Fagan's will be like when these youngsters bear the impress of a century's hand, and what might then be the tale that the trees could tell! Here again on the right we see the square beds for summer flowers. Between the beds just mentioned and the wall is a broad border of herbaceous plants, there being another one also running by the side of the only other wall; they contain the stock customarily placed in such positions, preference being given to those that flower in the summer and autumn.

The Pleasaunce.

Let the reader now accompany us to that most delightful part of an estate in the spring time—namely, the Pleasaunce. To reach it from the gardens through which we have just passed, we must descend the terraces, cross the lakes at the most convenient spot and ascend the slopes on the other side. But when the soft grass of the level walk on the ridge is reached, a more charming picture could not easily be imagined. On one hand we find a row of splendid Cedars (*Cedrus deodara*), with miscellaneous foliage and flowering shrubs on the other.

The water in the valley, the terraces beyond, crowned on the highest ground by the mansion of St. Fagan's—as a matter of fact, and digressing for a moment from our immediate topic, it is from this position that the only semblance of a castle can be seen in the form of one tower—make a most charming picture, which receives the admiration of every visitor. The Lilacs diffused a refreshing perfume, and the Daisy-speckled turf seemed to invigorate the muscles of the wanderer within the gates. As the length of the walk is traversed we see at intervals the boundaries of the maze (in which the hapless stranger, as was the writer, may be escorted and left to fathom its mysteries as best he can), an Azalea garden, occasional groups of Rhododendrons, handsome Magnolias, with their chalice-shaped flowers, and the Snowdrop Tree (*Halesia tetraptera*), with, as the ground again falls, Apple trees in numbers, and more beautiful still, Quinces in the lower grounds. We cannot

(*Colchicum autumnale*), with thousands of Narcissi, of which only *N. poeticus recurvus* remained to tell the story of past glories. Did we descend to the narrow stream which winds slowly through the valley, we should have to discourse of Marsh Marigolds, *Iris Kämpferi* and scores of other plants grown either for their flowers or their handsome leafage, but to separate which from their picturesque confusion would be to obtain precision at the expense of art.

The Terraces.

As may readily be seen by reference to the illustration (fig. 128, page 477), the ground on the opposite side to the pleasure rises from the lake in a series of terraces, supported by walls and balustrades of stone with flights of steps. To some of these there are grass banks with shrubs of various kinds, and on the upper one a broad border with

Photo by Mr. G. R. King,

Cardiff.

FIG. 130.—ST. FAGAN'S CASTLE.

make a pretence of indicating the evergreen and deciduous trees or these notes would become literally a list of names which could not prove very entertaining reading.

Grass Gardening

Though to all intents and purposes this forms an essential portion of the pleasure, it is sufficiently attractive to warrant a separate paragraph. It is a phase of gardening that must be encouraged, and it is a pleasure to see the intelligent interest that is taken in it at St. Fagan's. Mr. Hugh Pettigrew, the gardener in chief, does not enter upon his work in an indiscriminate manner as is demonstrated by the admirable way in which positions have been chosen for the various plants. For example, in one place we found ourselves in a veritable Primrose garden (though only a solitary flower was then visible); while in another position equally appropriate rose the tall spikes of *Camassia esculenta*. Again, there were Snowdrops, Scillas, autumn Crocuses

a row extending the whole length of splendid Lavender plants. These must make a most beautiful picture when, later in the year, they are in full bloom, and one can imagine the delicious fragrance that will rise from them to the mansion, the Dutch garden, and the Mulberry grove above. On some of the spaces on the banks plants of the Florentine Iris are flowering; while in other positions the lovely *Rosa Wichuriana* has been judiciously planted. This Rose has an enviable reputation in America, and one may reasonably suppose that it will luxuriate in the positions selected for it at St. Fagan's. *Rosa rugosa*, handsome alike in foliage, flower, and fruit, has been similarly employed, and in still another place on the slopes it is proposed to plant a Sweet Brier hodge. One observes here and there, both in the pleasure and in other portions of the grounds, comfortable seats on which visitors may rest, and appreciate at their leisure the beauty and fragrance with which they are surrounded. In the lakes, which it will be observed are formal in design, Water Lilies flourish, and these again add interest to the whole.

The Rosery.

The reader may gather from the foregoing remarks that the whole of the gardens and grounds at St. Fagan's bear the impress of antiquity; but this is in reality by no means the case. There are modern features that will improve under time's softening hand, and there are places where the new and the old are associated in pleasing harmony. Look, for example, at the Rose garden, which will in a few years become one of the pleasantest retreats on the estate. Only a short time ago the space enclosed by substantial stone walls was a rubbish heap, whereas now it forms the garden for the queen of flowers. In shape it is oblong, and in each corner we find large beds given up to different sections as well as varieties of Roses, while on the walls are some of the best climbing Roses that could be procured. These corner pieces are divided from the other beds by soft green turf, and the centre is occupied by a cone-shaped arbour, over which other climbers in addition to Roses are being trained. This erection, beyond its margin of grass, is surrounded by trellises on which Roses may ramble practically at will. Outside of this, again, is found a red brick trough about 30 inches wide and half as many in depth; water is admitted at different points, and it is proposed to have some of the choice smaller-growing Water Lilies placed therein; needless to say it will be stocked with fish at the first opportunity. The whole of the soil utilised in the formation of this garden has had to be carted in, and from its appearance we should infer that it would have been difficult to select any more suitable for the purpose.

Wall Gardening.

Mention is made in the preceding paragraph of the association of the old with the new, which result has been achieved by the aid of wall gardening. The grand old stone walls that abound on the estate are admirably adapted to this form of gardening, and Mr. Pettigrew purposes to make a distinct feature of it in the future. It is so peculiarly interesting that it is really a matter for surprise that it has not been more frequently attempted. Possibly its neglect may be ascribed to the fact that generally speaking the plants suitable for the purpose are not showy, but are of such beauty as only the most refined taste can appreciate and enjoy. Of course, we frequently see Wall-flowers and Antirrhinums, but beyond these there are scores of smaller growing plants that are available for the purpose. However, the establishment of a wall garden is essentially a question of time, and can hardly be placed on a level with the planting of a flower bed or the making of a Rose garden.

The Fisheries.

In all probability the title of this paragraph will, if only for a moment, recall to the minds of readers the great International Fisheries Exhibition that was held at South Kensington in 1883. There was on view, as the writer can well remember, an immense variety of things of interest connected with fisheries and allied pursuits. The fisheries at St. Fagan's aspire to no such universal glory, but they are, at the same time, of the greatest interest. As a matter of fact they consist of three trays or troughs, in which trout of two or three varieties are being raised for stocking the lakes and presumably the watercourse in the Rose garden. In the three watertight boxes at St. Fagan's there were quite fifteen hundred trout, varying in size from an inch to an inch and a half in length. A constant flow of fresh water is apparently the great desideratum, and this falls from the upper box to the centre one, whence it passes through the third, and escapes by the overflow; the depth of water maintained would be some 3 or 4 inches. The series of boxes is placed on a stand under a high wall, and is further shaded by overhanging trees; the locked lids are seldom raised when the sun is striking directly on to the water, and then only for a very short time. The youngsters are fed once a day on hard boiled egg rubbed through fine gauze, and they take it with avidity. Beyond the constant supply of moving water the points are cleanliness and the prompt removal of any fish that may, from some known or unknown cause, die. In any case the process is most interesting, and is so simple that anyone might undertake it.

Beauty versus Utility.

When Mr. Pettigrew first took over the charge of the gardens at St. Fagan's he found in immediate contiguity to the mansion Strawberries growing on a bank, and near his own house the ground given over to vegetables. He further learnt that his noble employers were flower lovers first and vegetable lovers afterwards. Thus utility had to give way to beauty, and the bank is now occupied with thousands of

flowering plants, and the vegetable quarters are divided into beds of Gladioli, Sweet Peas, Carnations, Phloxes, and Pentstemons; while in the adjacent garden, which was erstwhile given up to Roses, are magnificent Paeonies, and many other plants that will provide flowers for cutting. These are in very great demand, and the provision of beds in such positions as those described obviates the necessity of drawing from the beds and borders near the mansion to maintain the supply. Utilitarianism is not put aside entirely, for there are considerable numbers of fruit trees on the walls with bushes and standards of various kinds in suitable positions all in fine condition; while under glass we find Tomatoes and excellent Grapes. There are, too, the plant houses, but St. Fagan's is to all intents and purposes an outdoor place, and in that section lie its many striking beauties. With the occupation by flowers of the entire home garden, it became necessary to find a new place for the vegetables, which were eventually relegated to a field some distance away. This has been laid out and planted with various fruit trees, and is now becoming stocked with vegetables; many crops are of course well advanced, and others are being rapidly brought forward until in a short time all the space at disposal will be occupied. Even here beauty is combined with utility, for a few rows of Sweet Peas were observed growing well; but then Mr. Pettigrew is a member of the General Committee of the Sweet Pea Bicentenary Celebration, and as such should support the flower of the year.

An Afterword.

The afterword, or postscript, of a lady's letter is said to contain the gist of all that has preceded it, but no such claim can be made for the afterword to St. Fagan's. That more might be said is readily acknowledged, but for a writer to absolutely exhaust his subject in one article is so contrary to the tenets of journalism, that something must ever be left unsaid. Thus an excuse remains for further reference to these beautiful gardens, which are so cherished by Lord and Lady Windsor, and admired by all their visitors. One reference only to the charming village can be made, and that is simply that the main entrance to the castle from the main street passes through an avenue of Robinias, with some handsome Cedars of Lebanon spreading their arms on the right background. With Mr. Hugh Pettigrew and St. Fagan's we have done for the present, but there are others of that ilk in the neighbourhood of whom something must be told in the days that are to come.—ZINGARI.

The Temple Show.

I HAVE read with interest both your report of the Temple Show and "Scrutator's" comments thereon on page 460 of your last issue. I found the crush in the tents during the afternoon of the first day very uncomfortable, and wish some scheme could be devised that would facilitate the examination of exhibits and locomotion. It was practically impossible for anyone to adequately inspect all the exhibits, though I have heard of one remarkably clever individual who "saw the entire show in an hour."

I am writing now to state how much my views coincide with those of "Scrutator" relative to the size of the collections. It seems to me quite unnecessary for such immense collections of Begonias, Calceolarias, Gloxinias, and other similar plants to be shown, as we all are familiar with the general run of the varieties, and have a keen desire to see only the choicest of the choice when we go to the Temple. I should therefore support your correspondent's suggestion most heartily relative to the limiting of the collections to say fifty plants in from 6-inch to 10-inch pots, according to the habit of the several kinds. One friend goes even further than this and advocates the appointment of a censor, who shall have power to exclude everything that does not attain to his ideal of perfection from the tents. I cannot say I have much sympathy with this project, but I should be full of sympathy for the man to whom such a task was allocated, and who would certainly come in for quite as much abuse as the press censor has done during the South African war.

"Scrutator's" scheme is certainly a workable one, and I hope the Council will bear it in mind in arranging for this great show in 1901. It would relieve the pressure on the space and would permit of the several exhibitors displaying rather more taste in arrangement than is at present apparent. There is still too much packing in the stands, and this is bad for the plants as well as the visitors who wish to inspect them carefully.—COUNTRY VISITOR.

Ficaria grandiflora.—The *Ficarias* are *Ranunculus*-like flowers, attractive in blossom, and useful from their early period of blooming. *Grandiflora* is one of the best. It produces bright yellow flowers in spring, and although easily grown and succeeding in ordinary garden soil, in deep rich ground it is much more vigorous and free-flowering. It is a plant that might well be added to many mixed borders of hardy plants, meriting a place there both by reason of its pleasing appearance and period of blooming, for flowers are not then too abundant. The opportunity may be taken of referring to another *Ficaria*—namely, *ranunculoides* fl.-pl. This is also well worthy of attention, the bright yellow double flowers being extremely attractive.—B.

Diervilla præcox.—The genus *Diervilla* (or *Weigela*) provides us with some of our most beautiful flowering shrubs, and of these *D. præcox* is the first to bloom, opening its purplish red flowers in April, and continuing well into May. The origin of this plant is not exactly known, but most probably it is an introduction from Japan, and either a geographical or garden form of the better-known *Weigela rosea*. It is not so hardy as the majority of this genus, and requires the shelter of a wall in the northern and midland counties, but it is well adapted for training, as it makes rather long, slender growths, which will produce a good truss of flowers from nearly every joint. The leaves are ovate, serrated, nearly or quite sessile, and very woolly on both sides. The whole plant, in fact, is distinctly hairy, even to the calices of the flowers.—C.

Wayside Flowers.—Among the list of wild flowers that now crowd and jostle each other by the wayside and margin of fields in Buckinghamshire, these two are most conspicuous—Starwort and Speedwell. They come in the very prime of year, when all young things are jubilant. All along the dusty highway, by the hedgerow bank, there are patches of delicious blue and snow-white. It is only in April, May, and early June that we have such a wealth of blue colours—Violet, Hyacinths, and Speedwell. As the noon of the year comes, with higher temperature and keener light, blue makes way for the golden and richer hues, the yellows, scarlets, and crimsons—the glaring Zonals, the Marigolds, Asters, and lumpish Dahlias—the adjective was Dr. Lindley's. And oh for the rain! It is so badly needed, to wash the dust from the wayside flowers and refresh the springing corn. How eagerly the little things are waiting for it, stretching out their dimpled leaves, to feel the cool sweet rain. It is falling now, in thick gentle showers, for it is these that do most good; not the thunder rain, that dashes and splashes and runs away, without refreshing the root of a Daisy.—("The Echo.")

Potato Sets.—I think Mr. Strugnell is the only grower of Potatoes of whom I have read, who adopts the practice of planting his small tubers each year, of early varieties only, to produce finer sets specially for planting the following year. If he has adopted that practice long then he should be in a good position to tell readers of the *Journal of Horticulture* how far that practice tends to deterioration of stock or how little. It is a favourite doctrine of some writers on Potatoes, and I have often wondered how much authority they may have had for it, that by planting small Potato sets instead of those of good size the stock soon deteriorated, and became much less productive. According to their theory Mr. Strugnell's stocks, if he grows the same ones for several years, should now be very inferior. But is it really so? I wish someone would, by way of experiment, test the matter with say half a dozen of varieties, early, midseason, and late, planting say of each variety a dozen tubers of 1 oz., 3 ozs., and 6 ozs. in weight, on precisely similar lines, saving the stocks, again selecting from them tubers for planting of the same sizes as before, testing the produce in the same way, and doing it a third year at least, just to see what was the general effect on the stocks. But to equalise matters, the fourth year tubers all of equal size, say from 3 to 4 ozs., should be selected from each stock or variety, and be planted again under similar conditions. The product that year should fully determine how far the successional planting of small tubers as against larger ones tended to deterioration. The matter is worthy of being put to a very practical test.—OBSERVER.

Noteworthy Asparagus.—Mr. Hurlstone writes:—"I have read your paragraph in last week's *Journal* about *Asparagus*, and as you ask the question of weight I have enclosed a cutting from the "*Worcester Times*," setting out the weights of some shown at the Evesham show this week—"Some *Asparagus* of remarkable size and excellent quality was shown, and the following prizes were awarded: Best hundred: 1st, Mr. George (Persnore), weight 22 lbs.; 2nd, Mr. Bedenham (Benge-worth), 19½ lbs.; 3rd, Mr. R. Mason (Haselor), 17 lbs. 1 oz. The prize for the heaviest hundred went to Mr. G. Bolton, whose bundle weighed no less than 28½ lbs."

Campanula Raineri.—This is a sturdy little mountaineer from northern Italy, having large, erect, somewhat funnel-shaped blossoms of a dark blue, and is a most pleasing and distinct member of its genus. It is comparatively rare in cultivation, though by no means difficult to grow or to increase, and it is somewhat surprising that it is not more generally met with. It is more vigorous in habit than any other of the dwarf Harebells, and is adapted for the border or the rockery. It is readily increased by division and also by seed. It grows best in moist situations in very sandy loam, and is usually from 3 to 6 inches high, the latter height, however, being a rarity.—H.

Notice to Thieves.—The following weird notice to thieves, states the "*Western Mail*," appears on a notice board erected at the foot of a grave at Merthyr Dovan Cemetery, Barry:—"Beware of the eye of God when no other see you, Off the evil done to these that is at rest hear by willfully stilling plants from this grave been plased hear by the parents of those near and dear to thim, which as been done 5 different times. Seven choise plants as been taken within this past five wicks, 2 choicc cornations and other roots from the 15 to the 18 of this presant muntth. Shureley the hand of God sooner or later will punish the gilty of such ungrateful act."

Arbutus hybrida.—This is a natnral hybrid between *A. Andrachn e* and *A. Unedo*, and in its characters is intermediate between its two parents. It forms a small, well-furnished tree about 20 feet high under favourable conditions, and is rather hardier than the Strawberry Tree, so that it should be a welcome addition to the list of first-class ever-greens in most gardens of the southern half of England. In point of beauty it is surpassed by few of its class, and as an isolated specimen on a lawn leaves little to be desired. It thrives best in a good deep soil free of lime, and if it is of a peaty nature so much the better. The small, tubular flowers open from February to April, and are white with a faint tinge of lemon at the mouth, and are occasionally streaked with red on the outside. They are borne in terminal, branched racemes, on every shoot, and make a fine display when the plant is in full flower. Like the other members of the genus, this plant is impatient of removal, and should be kept in pots until it can be placed in its permanent quarters, as the shifting of even small specimens cannot be done without running considerable risk of losing them altogether. It can be propagated by grafting on *A. Unedo*, or by seeds, which are produced in warm localities, and which reproduce themselves fairly true to character.—J. C.

Cineraria Culture.—As I was more than usually successful last season with these handsome flowers, I will describe briefly my methods in the hope that they may be of service to my fellow amateurs. The flower heads were fuller than I have ever seen them. I have measured scores of the blossoms, and find several fully 2½ inches in diameter, and the colours exceptionally rich. The first sowing was made April 14th, 1899, in pans half filled with rough peat, to which was added a mixture of loam and peat finely sifted, with plenty of sand. The pans were then covered with glass, and placed on the higher shelves in a cool greenhouse. As soon as the plants showed their second leaves they were potted singly into thumb pots, using rather coarse soil, but taking care not to cover the hearts of the plants. They were then placed in a close frame shaded, and sprinkled morning and evening till well established, being kept close for a couple of weeks, after which more air was given. As soon as the pots were full of roots the plants were shifted into 4½-inch pots, and again at the end of September into 8-inch pots for the largest specimens. As soon as the flower buds showed the plants were liberally supplied with soot and liquid manure. Plenty of air was given night and day when the weather was suitable, and at all stages of their growth the plants were shaded from bright sunshine. The soil employed was equal parts of rich loam, leaf mould, and thoroughly decayed horse manure, mixed with charcoal dust and coarse sand.—AMATEUR.

Rose Show Fixtures in 1900.

- June 13th (Wednesday).—York.†
 „ 27th (Wednesday).—Salisbury (N.R.S.), Richmond (Surrey),* and Southampton.*
 „ 28th (Thursday).—Canterbury, Colchester, and Isle of Wight (Ryde)
 „ 30th (Saturday).—Maidstone and Windsor.
 July 3rd (Tuesday).—Westminster (R.H.S.), and Gloucester.
 „ 4th (Wednesday).—Croydon, Ealing, Farningham, Hereford, Reigate, and Tunbridge Wells.
 „ 5th (Thursday).—Bath, Norwich, and Sutton.
 „ 7th (Saturday).—Crystal Palace (N.R.S.).
 „ 10th (Tuesday).—Harrow and Wolverhampton.†
 „ 11th (Wednesday).—Brockham.
 „ 12th (Thursday).—Brentwood, Salterhebble, Woodbridge, and Eltham.
 „ 13th (Friday).—Ulverston.
 „ 14th (Saturday).—Manchester, and New Brighton.

 „ 24th (Tuesday).—Tibshelf.
 „ 25th (Wednesday).—Newcastle-on-Tyne.†
 „ 26th (Thursday).—Bedale.

* Shows lasting two days. † Shows lasting three days.

I shall be glad to receive the dates of any other Rose shows (or horticultural exhibitions in which Roses form a leading feature) for the next list of Rose Show Fixtures, which will appear in an early issue.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

Ethel Brownlow.

YOUR correspondent, "Specialist" (page 446), has arrived at a wise resolution to once again try the culture of this admirable Rose—delightfully tinted salmon pink and yellow. The yellow shades to a creamy white in early spring under glass. I got this from the raisers, Messrs. Dickson, Newtownards, as far back as 1889—the year after it was sent out—and ever since it has been a persistent bloomer, nine months out of every twelve, on the back wall of my greenhouse. It does admirably when well established on a south wall, but planted out under glass it does best. A companion for it would be Muriel Grahame (Tea), but it is not so vigorous.—W. J. MURPHY, *Clonmel.*

Perle des Jardins.

THIS Tea-scented Rose is not one esteemed by exhibitors, but it is highly favoured as a market variety. The clear light yellow tint of its blooms is always admired, and their medium size adapts them for all kinds of floral decoration. It is also a continuous flowering variety; the stem is of good length and stout, besides having remarkably striking foliage, so thick as to be almost mildew-proof.

To see this Rose in full beauty it must be grown under glass. We visited several long greenhouses filled with it at Woking recently. The grower, Mr. J. Wood, has cultivated "Perle" for a considerable number of years, the flowers going to the leading London market, and with such success that we fancy he would require something very much out of the ordinary way to oust his favourite. To judge, however, from the thousands of little plants of the newer Sunrise, it would appear that this is in the future likely to obtain a large portion of this grower's care. Mr. Wood is also raising seedlings himself, and has several very promising ones. He should know what the Rose public require, for we believe he had much to do with the propagation and growth of such grand sorts as Her Majesty and Mrs. John Laing before others had a chance of trying them, with the late Mr. Bennett.

The houses of "Perle" are certainly grand. When one opens a door there is before one a level mass of Rose buds in varying stages of development. The plants are no more than 2 feet high, in bush form, and exceptionally healthy and clean. Apparently there is not a great deal of trouble taken with them; that is they are not coddled, but the proper treatment is undoubtedly bestowed upon them. The older plants look quite aged judging from their thick base, but the fresh growth is all alike in vigour. Mr. Wood raises his own plants, a few being worked each year to replace any that may have become debilitated.

Pots of several sizes are employed, up to 12-inch ones, for the

oldest specimens. All are plunged half their depth in the ground; thus they establish themselves there in time, and are not often moved. The feeding with stimulants is given in the pots when required. The glass is never shaded, and this may account in some way for the deep colour Mr. Wood gets into the blooms. Some hundreds of dozens which we saw ready for the market were certainly remarkable in their depth of yellow for the variety.

A new nursery has been started by this cultivator near Ash, in this county. Here, although *Perle des Jardins* reigns supreme, other sorts are given a trial. *Kaiserin Augusta Victoria* is a white flower very much favoured, and the thousands of plants outside of Fisher Holmes would indicate that this is a good crimson sort to supply blooms throughout the summer.—SURREY.

Climbing Roses.

ONE of the best methods of growing Roses is to cultivate them as climbers. Many excellent positions are to be found round the walls of mansions, gable ends of buildings, trellised walls, pillars, and arches, where Roses would flourish well and form picturesque additions to the surroundings. This is not the proper season to plant Roses, except from pots, but it is an appropriate time to draw attention to the wealth of suitable varieties in the various sections of Roses which are unmistakeably adapted for this form of culture.

Ayrshire Roses are best for covering rough work, arches, pillars, and tree trunks. They grow rapidly, the habit of the plants being slender with trailing stems. The leaves are shining, and the flowers are borne in clusters. *Dundee Rambler* is one of the best varieties. *Ruga* is very fragrant, of a pale flesh colour, and splends, of the same colour as the first named, white, tinged with pink, is myrrh-scented. The evergreen Roses are of similar rapid growth to the foregoing, and, as their name implies, retain the foliage far into the winter. They are well adapted for furnishing rough spaces, fences, walls, and bear immense clusters of bloom. *Félicité Perpetué* has cream white flowers. *Rampant* pure white, and *Fortune's Yellow* copper and fawn, are singularly beautiful.

The Cluster Roses are distinguished by bearing immense corymbs of rich-coloured blooms. They have fine foliage and a vigorous habit. *Fragrans*, bright rose, *Laura Davoust*, rose, *purpurea*, purple red, and *Claire Jacquier*, creamy yellow, are the best varieties. In the *Polyantha* Cluster Rose class there is one variety which has of late years taken a high position as an excellent climbing or pillar Rose. This is *Turner's Crimson Rambler*, crimson scarlet. *Boursault* Roses are very distinct and handsome, grow rapidly, and bear strikingly gorgeous blooms in large clusters. *Amadis*, crimson, *Blush*, pale pink, and *elegans*, purple, white stripe, are good varieties. *Prairie* Roses are robust, vigorous climbers, especially on a south or west aspect. *Baltimore Belle*, white, shaded pink, is an excellent variety. In the *Bourbon* class a fine representative variety of a rich dark red colour is *Madame Isaac Pereire*; *Acidalie*, blush white, and *Sir Joseph Paxton*, lilac crimson, are both excellent.

Banksian Roses rank among the best climbers for walls, as they prefer a warm sheltered position. They flower early, making vigorous growth. The bloom is produced in clusters on the laterals from the previous year's shoots. *White Banksian* is very fragrant. The colour is a creamy shade of yellow. *Jaune Serin*, bright yellow, produces the largest blooms. *Musk* Roses are vigorous in growth, and are very suitable for making a display in autumn, at which time they bloom in profusion. Walls with a south-west aspect will suit them better than other positions. The blooms are deliciously fragrant. *Princess de Nassau*, cream, and *Rivers' Musk*, cream white, are good. The *Macartney* Roses, which include a single white named *alba simplex*, with shining foliage, *Maria Leonida*, double white, almost evergreen, are, like *Musk* Roses, best grown a warm wall. They are autumnal blooming.

Noisette Roses belonging to the strong growing section are specially adapted for walls on a south aspect. Among the best varieties are *L'Idéal*, yellow, red streaks, finely scented; *Lamarque*, a free grower, pure white, shaded lemon blooms. *Alister Stella Gray* is specially good; flowers similar to *W. A. Richardson*, produced almost continually in clusters. *Aimee Vibert* also blooms in clusters, the flowers being pure white. The best large white *Noisette* is *Madame Alf. Carrière*, ivory white, a good climber. *Maréchal Niel* should be tried in a good position. The blooms are bright yellow. It is one of the finest climbers grown, but will not succeed everywhere outdoors. *Triomphe de Rennes* is a free grower with yellow blooms.

Tea Roses possess many excellent varieties which only show their true character as climbers. They should have the protection of a wall and be planted in good soil. *Gloire de Dijon* will succeed on any aspect, and may be freely planted on walls, pillars, and trellises. It blooms early and late, and is very sweetly scented. The colour is fawn or buff with an orange centre. *Cheshunt Hybrid* is a good, hardy climbing Rose, vigorous in growth, with blooms of a cherry carmine colour. *Climbing Niphetos* is white, *Climbing Devoniensis* also white, and a free grower. *Madame Berard* is a clear salmon rose, and *Perle*

des Jardins yellow. Of the latter there is a climbing and a non-climbing variety. The climber is a rampant form of the dwarf type. Reine Marie Henriette should be grown in company with Gloire de Dijon, as it is almost a red form of the latter, and is a free climber.

Hybrid Perpetuals do not include a large number of climbers, but some varieties are well adapted for wall and fence culture. Among them may be included Jules Margottin, carmine; Glory of Waltham, crimson; Charles Lefebvre, velvety crimson; Blair No. 2, rosy blush; and Victor Verdier, cherry red.

Single Roses make splendid climbers if such varieties as Paul's Carmine Pillar and Single White are planted. Good positions might be afforded them by the sides of walks, training the growths on wire arches.—ROSARIAN.

Diseased Tomato Plants.

No. 1 plant, with marks of black on the stem and also the fruit, is infested in the root-stem with root-stem eelworm (*Tylenchus obtusus*), but the infection in the leaves and fruit is not sufficiently developed to admit of identification. It appears, however, to be what is called "spot," or "black stripe." The eelworm has almost destroyed the bark and soft-tissues portion of the root-stem, and the plant would soon have been destroyed, though its existence might have been prolonged—probably sufficiently long to ripen the fruit—by earthing it up, so as to secure fresh supporting roots from the stem above ground. No. 2 plant, that began to flag and wither without any apparent cause, is affected with "sleepy" disease fungus (*Fusarium lycopersici*), the woody tissues being quite browned by the parasite, and this not only in the root-stem, but a considerable distance up the stem above ground. Thus, with the supplies of nourishment cut off—for the fungal hyphæ destroy the tissues or conduits of the sap—the plant, as soon as girdled internally, must wither and die. The placing of turf round the stems of a few plants that suffered similarly, and keeping plentifully watered, with the result that they have mostly recovered, is very interesting and instructive.

The leaf from a plant of Challenger simply implies a disguising of the chlorophyll or green colouring pigment, the white overpowering the chlorophyll granules, and is a sort of parasitism, inasmuch as the white lives or forms at the expense of the green. It is probably due to the excessive formation of some oxalate, probably that of lime, the incrustation on the dead portion of the leaflets being certainly of a calcic or lime nature. The case resembles that of white variegation or complete albino, as in white Celery. Perhaps a little nitrate of ammonium, unfortunately too expensive for general use, would probably change the colour, giving the chlorophyll granules sufficient energy to overpower the blanching element or elements.

For the eelworm and also for the sleepy disease there are no better preventives than lime and kainit. As a particular preventive and nutrient for the Tomato, Mr. W. Dyke applied 2 lbs. of basic slag phosphate and 12 ozs. of kainit per square yard, and mixed this dressing with the soil about a foot deep in the early winter and left it until the following spring or planting time for the Tomato plants, the border being previously turned over a spit deep. He reported good success in the *Journal of Horticulture* from the treatment, though not quite absolute freedom from "sleepy" disease. As the basic slag is nearly half free lime, and this acts on the organic matter upon which sleepy disease exists as a saprophyte, and then passes to semi or complete parasitic state, the treatment is only a modification of what we have frequently advised. This is effected as follows:—Apply 1 lb. per square yard of freshly burned best chalk lime, slaked with the smallest quantity of water to cause it to fall into a fine powder, then spread evenly and dig in with a fork, taking small spits so as to insure an even mixing of the lime with the soil about a foot deep. On the level surface distribute 8 ozs. of best quality kainit, and leave to dissolve and pass into the soil. The quantity of kainit as proposed for a square yard and the liming and the salting should be performed some time in advance of cropping, at least six weeks, and preferably double that time. Dig the ground with a fork, and taking small spits at the middle of the period.

Cornus Mas.—Though an old-fashioned plant this is not seen as often as it might be, considering its value as an early spring-flowering shrub and the ease with which it can be grown. No matter whether the soil be sandy or clayey, this plant seems to thrive and flower freely every season. It commences to bloom about the middle of February and continues to the end of March, making a pleasing display with its clusters of bright yellow flowers, which are borne in bunches of from twenty to thirty enclosed in four rounded bracts. In good seasons the flowers are followed by the pendulous red fruits. There is a good white variegated form of this plant which fruits even better than the type, and grows quite as freely. C. Mas can easily be propagated by seeds, which germinate readily and soon form good plants. The variegated form must be either raised from cuttings or by grafting on the type.—C.

A Spring Garden.

No season of the year is so full of beauty as the spring, and at no other season do we enjoy such a wealth of floral variety. When we look back, thinking of the days that are no more, and consider all that they have taken from us, and how life has altered, yet with each returning spring we feel the lasting truth of the poet Keats' sentiment, "A thing of beauty is a joy for ever." Such is the garden, such the face of Nature at this season. It may be some picturesque piece of landscape, some wayside cottage garden, some noble tree or shrub, we have long known, and whose beauty is still here cheering us! Nevertheless, despite this wealth and profusion of loveliness, our gardens are often lacking in hardy flowering or ornamental shrubs and hardy spring flowers. I will therefore endeavour to draw a picture of an old-fashioned manor house in the county of broad acres as its beauties were revealed to me in the month of May.

The southern, eastern, and western grey stone walls, which date back to Tudor times, were clothed with climbing plants, while the northern front was garbed in Ivy. These are some of the flowers of May that greeted me on the occasion of my visit. Clematis montana festooned in white starry flowers rambled about the entrance porch, Wistaria sinensis hung luxuriant and showing its pale blue chains, Choisya ternata bowed with fragrant flowers, while the quaint catkins of Garrya elliptica lent an additional attractiveness. A touch of golden colour was added by the flowers of Kerria japonica flore pleno, the leafage of the variegated Euonymus japonicus, and the Golden Ivy. On the western gable Prunus triloba fl.-pl. garlanded with soft blush pink, and the white P. sinensis fl.-pl. displayed their loveliness; here and there the grey stone was allowed to show its neutral tint to give variety.

A few simple flower beds in a sheltered corner of the lawn made a charming picture, before which many a garden belonging to our stately homes would pale. The central bed, 7 feet in diameter, had a cluster of primrose Wallflower in the centre, around which in panels, separated by the yellow leaved Lamium, were Alyssum saxatile, Aubrietia Leichtlini, and Myosotis dissitiflora. Two narrow scroll-shaped beds were each filled with blood-red Wallflowers, bordered with white double Daisies; while two other scrolls contained double white Rockets, edged with red double Daisies.

The grounds, though only a few acres in extent, were full of interest at almost any time of the year. A belt of Austrian Pines sheltered them on the north and east, while an Ivy clad wall divided them from the main road on the west. On the southern side the lawn was separated from the park by a sunk fence, and bordered on the outskirts by clumps and single specimens of flowering shrubs. Here a noble Cedar of Lebanon spread out its mighty arms. There the flowering shrubs included a bush, 6 or 7 feet in height and as much in diameter, of Pyrus (Cydonia) japonica umbilicata, which was a glorious sight with its pendulous shoots clothed in rosy scarlet flowers. Cydonia alba and the type were grown as unpruned bushes, and whoever saw them grown thus would not train them against a wall and spur them in as is frequently done. The dwarf-growing C. Maulei was represented by a clump of three plants, whose branches were wreathed with orange-scarlet flowers; while the large white cup-shaped flowers of a fine plant of Magnolia conspicua bulked prominently on the view.

Several Japanese Maples, though not large, gave a rich glow of colour; they were Acer polymorphum, A. polymorphum atropurpureum, and A. palmatum sanguineum. Here a clump of Rhododendron Cunningham's Blush did not belie its name; there were several fine specimens in cool places of Azalea pontica and the Ghent varieties. A small bed of A. mollis looked charming with its rich and glowing colours, and a small group of the feathery-leaved scarlet Elder (Sambucus racemosa plumosa aurea) glowed beautifully in the lemon yellow of its lacinated foliage, blended with the orange colour of the emerging leaves of the crown.

Passing to the northern side of the house, where, after leaving the walk, the ground rose rather abruptly. Advantage of this had been taken to form a rockwork from the gravel walk to a height of 12 feet. This rockwork had been formed by large square slabs of rough stone sunk a foot into the soil, and made a step-like series of receptacles a yard in width, and having sufficient depth of soil to allow shrubs to flourish. This rockwork was always full of interest, and the month of May was particularly rich in its display. Noticeable was a huge bush 5 feet in diameter and of proportionate height of Genista præcox albus literally weighed down with its snowy white racemes. Groups and single specimens of G. præcox (sulphur and yellow) were seen, as well as G. scoparia grandiflora with its golden flowers. There, too, were masses of G. tinctoria plena and Ulex europæus plenus (double Furze). Daphne Fioniana was represented by a bush 4 feet in diameter and a yard in height, every shoot bearing a truss of sweet scented flowers, while many fine-leaved Ivies rambled over the stones, mixed with the pale blue Periwinkle (Vinca major) and Euonymus radicans variegatus.

On the ground above the rockwork were masses of *Berberis Darwini*, *B. stenophylla*, and *B. dulcis*, with Lilacs, Laburnums, the Snowy Mespilus (*Amelanchier botryapium*), the Almond, *Pyrus Malus baccata*, the scarlet Siberian Crab, Japanese Crabs, and the double-flowering Cherry (*Cerasus avium multiplex*), to all which a group of *Prunus Pissardi* imparted a rich purple colour, making this bank a living picture of the changing year. Variety in the form of a heterogeneous mixture of trees, shrubs, and formality still clings to the ordinary landscape gardener; but those who love stately foliage and beautiful flowering trees will not permit confusion. Freedom of growth was practised here. Flowering shrubs had been judiciously pruned for a year or two after planting to make the foundation, and afterwards only the dead wood or crowded growth had been thinned out.—F. STREET.

Celmisia spectabilis.

This plant must be accorded a foremost position amongst the introductions of the last two decades, and though it is still comparatively rare, it is gradually gaining a place in popular esteem. *Celmisia spectabilis* (fig. 131) is a composite plant of striking beauty, and the form of its flower and the habit of growth are both shown in the illustration. The plant usually grows to a height of about 6 inches, and has narrow lanceolate leaves, which are white and woolly on the under surface. The flower heads are 2 inches in diameter, with closely set, narrow, pure white ray florets, and a golden disc. Being very compact it is well adapted for culture in pots in a cool house, or it may be found useful out of doors. If "R. T. R." requires any further information relative to this plant he must write again.

The Royal Horticultural Society.

Drill Hall, June 5th.

CONSIDERING the fact that it is holiday time, the exhibition on Tuesday was a most excellent one. Not only was there diversity in the exhibits, but also quality, which was observable throughout the entire show. The finest features of the entire exhibition were the *Eremurus* from Messrs. J. Veitch & Sons, the vegetables from Messrs. Sutton & Sons, and the two boxes of Nectarines from Messrs. T. Rivers and Son. Orchids are never very numerous at this period of the year, and quality had to take the place of quantity.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with Messrs. E. Beckett, G. Kelf, J. H. Veitch, A. H. Pearson, A. Dean, S. Mortimer, G. T. Miles, W. Bates, G. Wythes, J. Smith, G. Norman, H. Balderson, H. Somers Rivers, and H. Esling.

Messrs. Laxton Bros., Bedford, staged Strawberries Leader, Fillbasket, Mentmore, Trafalgar (Latest of All and Frogmore Late Pine), Climax (Latest of All and Waterloo), in excellent condition. Trafalgar is an attractive fruit, that will probably be shown to better advantage later in the season. Mr. E. Beckett, gardener to Lord Aldenham, Elstree, sent some splendid fruits of Lord Napier Nectarine; while Mr. J. Hudson, gardener to L. de Rothschild, Esq., Gunnersbury, contributed Nectarines Lord Napier, Early Rivers, and Cardinal, all in splendid condition. Messrs. T. Rivers & Son, Sawbridgeworth, sent Nectarines Early Rivers and Cardinal, in perfect condition; the fruits were of remarkable size, and evidenced the best of culture.

Messrs. Sutton & Sons, Reading, occupied almost the whole of one side of the hall with a collection of vegetables. These included Peas, Cucumbers, and Potatoes growing either in pots or boxes, and dishes of Tomatoes, Cucumbers, and Potatoes. The plants were splendidly grown, and included Peas Sutton's Early Giant, Sutton's A1, May Queen, and Empress of India; Cucumbers Lord Roberts, Peerless, and Sutton's A1; Potatoes Ringleader, Ninetyfold, May Queen, Sutton's A1, Harbinger and Sutton's Ashleaf; and Tomato Winter Beauty. This was a most striking exhibit, and was the centre of a considerable amount of attention.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, R. Dean, J. F. McLeod, R. Fife, C. Jeffries, W. Bain, J. D. Pawle, J. T. Bennett Poë, C. E. Shea, E. H. Jenkins, H. J. Jones, C. Blick, E. T. Cook, G. Paul, J. Walker, G. Reuthe, J. Hudson, J. Jennings, and E. Mawley.

Messrs. W. Paul & Son, Waltham Cross, again arranged a large group of Roses in pots, with baskets of cut blooms, and a few boxes filled with specimen blooms. Crimson Rambler and the Wichuriana Roses, Pink Roamer and Gardenia represented the garden Roses, while standard specimens of Enchantress, Bridesmaid, Helena Cambier, Madame de Watteville, and Madame Cusin were charming. The cut

flowers included Maman Cochet, La France, Madam Wagram, Tennyson, Duchess of Albany, Marquis Litta, and some promising seedlings.

One of the most attractive exhibits in the hall was that from Messrs. Jas. Veitch & Sons, Ltd., Chelsea, which was composed of a grand collection of *Eremurus* with a groundwork of *Primula japonica*. The *Eremurus* included *E. robustus* and *E. himalaicus*; these were remarkable for their huge size and splendid development, and it is doubtful if a finer exhibit of these plants has ever been seen, and the interest evinced from all classes at the show only tended to show how much they were appreciated. Hardy flowers and Clematises were arranged by Messrs. G. Jackman & Son, Woking, the Campanulas, Pyrethrums, Irises and Clematis hybrids being especially noteworthy, the latter including Duchess of Albany, Duchess of York, and Countess of Onslow. Campanulas Mariesi and *C. persicifolia alba grandiflora* were conspicuous, as were also *Aquilegia californica*, and a number of Pyrethrums.

Messrs. Dobbie & Co., Rothesay, had a beautiful table of Sweet Peas, with a few good African Marigolds. The Sweet Peas were well arranged in vases, but the groundwork of dark blue was detrimental to the colours of the flowers. The chief varieties were Modesty, Peach Blossom, America, Triumph, Mars, Meteor, Lovely, Aurora, Mikado, Lady Penzance, Oriental, Lady Mary Currie, and Gorgeous; these were all in capital form.

Messrs. Kelway & Son, Langport, occupied a table running the entire length of the hall with a collection of herbaceous Pæonies and Pyrethrums. In the former section, Briton Ferry, Langport Belle, Lord Panncoforte, Dr. Bonavia, and Mrs. Gwyn Lewis were excellent, while the tree Pæonies Lord Roberts, Countess Crewe, Mrs. Beerbohm Treo, Lord Kitchener, and James Kelway were beautiful. The Pyrethrums James Kelway, a deep crimson semi-double, Firefly, Fairfax, Apemantus, Lady Synons, and Rosetta in the singles, and Alfred, Ernest Figaro, Melton, Captain Nares, Lady Kildare, and Leonard Kelway were the best of the double forms. Messrs. Wallace and Co., Colchester, arranged a tasteful display of hardy flowers. The Irises, Pæonies, and Calochorti formed the chief features, but these by no means completed the display. The Lilliums were especially interesting. Brodiaeas were also strongly in evidence, while the Ixias, German Irises, and *Eremurus* made a very interesting exhibit.

Rhododendrons from Messrs. W. Paul & Son, Waltham Cross, occupied a large space, and a capital display they formed, arranged in baskets and boxes. Varieties that appeared to tower above their neighbours for size and colouring were Alarum, Athene, Michael Waterer, The Queen, Sappho, Lady Dorothy Nevill, Sir R. Peel, and James Bateman. It should be added that these flowers were all produced in loam, and those who have had the pleasure of walking through the Loughton nursery, where they are grown, can testify to the stability of the soil for clinging to the boots, showing that there is no vestige of peat in the soil.

A delightful bank of Gloxinias was arranged in Maidenhair Fern by Messrs. Jas. Veitch & Sons. The plants were well flowered, and the colours particularly bright. Monarch and Empress of India are both exceedingly bright crimson varieties, while Virginalis, Seraph, The Bride, Mephisto, and Elaine were attractive and bright. Mr. H. J. Jones, Ryecroft Nursery, Lewisham, had an extensive exhibit of Begonias, Gloxinias, and hardy flowers. The Begonias were dwarf and well flowered. In the single section Starlight, Gloriosum, Nero, Mrs. T. Lunt, and Jealousy were best. The doubles included May Clarke, Mr. Walter Kinch, a fine crimson; H. A. Weeks, and May Crawford. The hardy flowers comprised some beautiful bunches of Spanish Irises, such as Thunderbolt, Golden King, Purple King, and British Queen. The early Gladioli were also beautifully developed, while the whole table was draped with *Panicum*, *Ficus repens*, and Ferns.

Messrs. R. & G. Cuthbert, Southgate, staged a table of hybrid Spiræas in fine condition. The varieties were Dr. Cattie, Professor Suringar, Queen of Holland, a lovely form; H. Witte, and W. E. Gladstone. From Messrs. Paul & Son, Cheshunt, came some vases of new Roses, Rhododendrons, and a tricolor Beech. The Roses included J. B. M. Camm, a grand variety; The Queen of Sweden and Norway, a promising Tea; and a single *Rosa sinica* hybrid Anemone; also Rhododendrons Duke of York, a bright rose pink, and the Duchess of York, a paler variety. Garden Roses were exhibited in good form by Messrs. F. Cant & Co., Colchester. The varieties were Pink Scotch, Harrisoni, *Rosa alpina*, Paul's Carmine Pillar, rugosa alba, and r. rubra, with a few other varieties. An interesting display of hardy flowers was staged by Messrs. T. S. Ware, Ltd., Feltham. The Irises and Lilliums were good, while the little rock and alpine plants appeared to interest the visitors.

Messrs. Barr & Sons, Covent Garden, had a choice arrangement of Pæonies, Irises, and alpine plants, with a general collection of hardy flowers. In the Irises, Neglecta Virginia, I. Biliotti, I. pallida Queen of May, I. variegata Gracchus, I. pallida Astarte, and I. p. Albert Victor were effective. The most showy Pæonies were Flesh White, atro-rubra plena, and anemoneflora plena. The Oriental Poppies, Brightness, bracteatum, and Perfection, added a brilliancy to the exhibit. Messrs. R. H. Bath, Ltd., Wisbech, staged a small group of a new yellow Carnation, Lord Roberts, which appears to be a good variety with a non-bursting calyx. A welcome group of Carnations was that arranged by Mr. H. Dixon, Woodside Gardens, Hailsham. The plants were healthy, and the flowers well developed. The best were

Belladonna, Barras, Miss Violet, F. Wellesley, Isinglass, The Cadi' Belladonna, and Lady Hindlip. Mr. Walters, gardener to Lord Gerard, Ashford, had a small exhibit of the Carnation Lady Gerard, a pale primrose variety of the Malmaison type; and Mr. S. Bide, Farnham, sent a basket of Calla Primrose Dame, a pale yellow of the C. Elliottiana type. Messrs. Paul & Son, Cheshunt, exhibited a basket of Senecio lilacinus, a species from South Africa. A box of hybrid Rhododendrons were exhibited by Messrs. J. Veitch & Sons, Ltd. The varieties were those that have so often been seen during the past winter, except that they are a little brighter in colour at the present time.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, H. Little, H. T. Pitt, F. Sander, H. J. Chapman, W. H. Young, H. A. Tracey, J. Wilson Potter, W. H. White, E. Hill, J. Douglas, J. Colman, and W. Cobb.

Mr. W. H. Young, Orchid grower to Sir Frederic Wigan, Bart., Clare Lawn, East Sheen, contributed a brightly attractive group of Orchids. The plants were splendidly grown, and carried excellent flowers. Amongst others we observed Cattleyas Mendeli Prince of Wales, Warneri, Mendeli Nellie Wigan, Mossiae, M. E. Ashworth, and M. Reineckiana, Thunia Marshalliana, Lælias tenebrosa and purpurata, Phalaenopsis fuscata Manni and grandiflora, Aërides Fieldingi, Lælio-Cattleyas Arnoldiana and eximia, Dendrobiums Farmeri albens, Owenianum, and Farmeri, Odontoglossums citrosimum and crispum, Cypripediums in variety, Miltonias, Cymbidium tigrinum, Lælia Brassavola Digbyana, and Masdevallia Harryana.

A charming group of Orchids was arranged by Mr. F. W. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill. The plants were not numerous, but showed admirable culture. There were Cattleyas, Lælias, Miltonias, Dendrobiums, Cypripediums, Oncidiums, and Odontoglossums, including the Rosslyn variety of excellens, which received a first-class certificate in 1898, when it carried ten flowers, in 1899 it carried nine flowers, and on this occasion had ten flowers; it is now said that this is a form of Loochristyensis.

There were numbers of small exhibitors of Orchids. Sir James Miller, Bart., who sent Lælio-Cattleyas Martineti and Lady Miller; W. A. Gillett, Esq., a form of Odontoglossum crispum; R. I. Measures, Esq., Miltonia vexillaria, Cambridge Lodge var., and Saccolabium ampullaceum mculmeinense (this is the original plant that was certificated in 1868); Mr. E. Kromer, Oncidium nallum; Mr. H. Tracey, Cattleya Mossiae and Brassia longissima; Mr. J. Douglas, Cattleya labiata Warneri (these flowers were from the original plant showed by Mr. Rucker and certificated in 1866); A. H. Smee, Esq., Cattleya Mossiae hackbridgiensis, C. Mendeli hackbridgiensis, and Cypripedium Lawrenceanum hackbridgiensis; de Barri Crawshay, Esq., Odontoglossum crispum Cecile de Rechfort, O. citrosimum rosefieldiense, O. Andersonianum candidum, and O. elegantius (a natural hybrid from O. Pescatorei and O. Lindleyanum); and Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Dendrobium Dalhousianum.

MEDALS.—Fruit Committee.—Silver-gilt Knightian medals to Messrs. Sutton & Sons and T. Rivers & Son; silver Knightian medal to Mr. J. Hudson; silver Banksian medals to Messrs. E. Beckett and Laxton Bros. Floral Committee.—Gold medal and silver Flora medals to Messrs. J. Veitch & Sons; silver-gilt Flora medal to Messrs. Kelway and Son; silver Flora medals to Messrs. Dobbie & Co., Jackman and Son, H. J. Jones, and Wallace & Co.; silver Banksian medals to Messrs. Barr & Sons, T. S. Ware, H. T. Dixon, and W. Paul & Son. Orchid Committee.—Silver Flora medal to Mr. W. H. Young, and silver Banksian medal to Mr. F. W. Thurgood.

Certificates and Awards of Merit.

Begonia Gladys Hemsley (H. J. Jones).—An excellent double variety of a soft salmon colour (award of merit).

Dendrobium Dalhousianum (W. H. White).—A handsome flower, of which the parentage is indicated in the specific name. It has all the colour of nobile with the size and much of the form of Dalhousianum (award of merit).

Lilac Madame Abel Chatenay (W. Marshall).—A double white variety of the first size and form (award of merit).

Pæony Lady Curzon (Kelway & Son).—A fine herbaceous variety; the colour is delicate blush (award of merit).

Pæony Lord Roberts (Kelway & Son).—A superb silvery white variety of the tree section (award of merit).

Pæony Cream Perfection (Wallace & Co.).—The varietal name admirably describes the colour of this superb flower (award of merit).

Rhododendron Pink Pearl (W. Bain).—A magnificent variety; the flowers are large, and of soft pink colour, with brown spots on the upper portion (first-class certificate).

Rose sinica Anemone (Paul & Son).—A free growing single variety of rich rosy red colour (award of merit).

Rose Tennyson (Wm. Paul & Son).—A Hybrid Tea of perfect form; the colour is delicate rose (award of merit).

Rose Pink Roamer (Wm. Paul & Son).—The varietal name tells both colour and habit; it is a splendid Rose (award of merit).

Streptocarpus achimenesiflorus (J. Veitch & Sons).—This splendid strain is illustrated and described on page 479 (award of merit).

Horticultural Shows.

Cheltenham.—May 30th.

ON the 30th ult. the above show was held in the Montpellier Gardens of the garden borough of Gloucestershire. The weather was fortunately all that could be desired. Mr. Cypher, as usual, proved invincible. The groups of plants arranged on a space covering several hundred feet were very fine indeed, and the first honours went to Mr. Cypher's exhibit. It consisted of a series of independent groups, backed up with splendidly grown elegant Palms and other foliage plants. Underneath was a rustic arrangement of virgin cork into which were placed choice Orchids of the finest and most suitable kinds. This group was a masterpiece of art. In the second place came Mr. Vause of Leamington, who displayed a similar arrangement in his usual excellent style. Mr. Cypher also carried off first honours for a

FIG. 131.—CELMISIA SPECTABILIS.

group of Orchids, among which we noticed some very choice varieties of Lælia purpurata, Dendrobiums, Cattleyas, particularly C. citrina. Mr. Marsh, gardener to the Rev. Butt, showed, but not for competition, a large and notable group of stove and greenhouse plants, and also a very fine arrangement of Orchids, amongst which were choice Lælia purpurata.

The first prize for ten greenhouse and stove flowering plants was also taken by Mr. Cypher, amongst which were very finely grown plants of Erica Cavendishi, Bougainvillea Cypheri, a splendid variety; Anthurium Cypheri, Phœnocomma Barnesi. Mr. Vause followed with another fine group. Indian Azaleas were well shown by Mr. Cypher and Mr. Marsh; and fruit by Mr. Hortick, Cowley Manor. In the bouquet section Messrs. Pates & Sharpe secured first place, and Mr. Vause second. There were also several meritorious exhibits, but not for competition—namely, a splendid assortment of choice cut flowers of Messrs. Pates & Sharpe; and excellent hardy cut flowers

of Mr. Whitto, of Worcester. Certificates of merit were awarded to Mr. Marsh for some splendid Indian Azaleas, and for a splendid group.

Manchester.—June 2nd.

NEXT in importance of the earlier season shows to that of the Temple comes Manchester, a city which contains so many enthusiastic amateurs as to make one wish that the conditions under which the plants grow were more favourable. It is approaching the half century since the first of these great Whitsun-week exhibitions was organised, and during this time the society has emerged from many difficulties which to many would have appeared almost insurmountable. With a president like Thomas Statter, Esq., of Stand Hall, Whitefield, a gentleman so well known in the Orchid world, with Mr. P. Weathers, the energetic orator, and Mr. Paul, his able assistant, the Manchester show enjoys a directorate which will not readily allow it to recede from its achieved high position.

For many years the exhibition has been opened on the Friday previous to Whit-Monday in the Royal Botanical Gardens, but this year Saturday was chosen, and a lovely day, though perhaps a little too warm. So good were the Orchids that in the opinion of some judges the groups were superior to those at the Temple. Messrs. Sutton & Sons, Reading, took the gold medal with some lovely spotted forms of Gloxinias; Messrs. Kelway & Son also won a gold medal with a most handsome stand of Pæonies, double and single, Pyrethrums, Irises, and many delightful outdoor flowers; and Messrs. John Peed & Son were awarded a third gold medal for their group of magnificent Caladiums. The Bagshot Rhododendrons, which occupied almost half the large annexe, were in the pink of condition, and for these Messrs. Anthony Waterer & Son also received the society's gold medal. A gold medal was also awarded to Messrs. W. Cutbush & Sons, Highgate, who furnished a huge bank of fine flowering plants, consisting of tree Carnations, Oranges full of fruit, Heaths, and a miscellaneous variety of excellent quality. Their animals in plant life growing in tubs caused much surprise by their quaint appearance.

The Orchids were certainly remarkable for their beauty and wealth of rich varieties, and there was no gainsaying the fact that Mr. James Cypher, of Cheltenham, not only won the gold medal, but won golden opinions for excellence in the arrangement of his group. Mr. Cypher's *Cattleya Mossiæ* delicatissima, a lovely pale blush sepals and petals, with purple and rich gold throat markings, was greatly admired, and his Lady Roberts, a very dark purpurata, received an award of merit. Messrs. J. Heath, of Cheltenham, who ranked second, had fine *Lælia* and types of *Cattleya Mossiæ*. Messrs. E. Ashworth and T. Statter were first and second amongst amateurs. Conspicuous here were the Harefield variety of *Cypripedium Rothschildianum*, and the two *Odontoglossums*, Arthur and Ernest Ashworth, which received first-class certificates. In the class for ten specimen Orchids in bloom, Mr. Cypher emerged at the top with great plants of *Dendrobium nobile splendens*, *Lælia purpurata* Queen Empress, a gorgeous variety (award of merit), *Cattleya Mossiæ* Distinction, fine *Miltonia vexillarium*, and *Oncidium serratum*; Messrs. Heath & Son were again second, while Mr. Mulloy, gardener to T. Harker, Esq., Wiltlington, came third.

And now to chronicle the non-competing section of Orchid exhibitors. Messrs. Charlesworth & Co., Heaton, Bradford, for beautiful plants of *Oncidium Marshallianum*, *Cypripedium Chapmani* heatonense F.C.C., the light and dark forms of *Mendeli Psyche* and *Excelsior*, *Cypripedium Vipani*, *Lycaste Ballæ*, *Odontoglossum crispum* Imperator, *Cattleya Mossiæ* magnifica, received awards of merit. A F.C.C. was also deservedly granted for *Odontoglossum* Lady Primrose, which has pure primrose sepals and very charming petals. Mr. John Cowan shared with Messrs. Charlesworth & Co. the distinction of being awarded two first-class certificates for *Cælogyne pandurata* and *Cypripedium Lawrenceanum* Hyeannum, and an award of merit was granted for a splendid large flowered type of *Cattleya Mossiæ*, and cultural certificates for an immense specimen *Cattleya Mossiæ* carrying over fifty flowers, and a well flowered fine variety *Odontoglossum crispum*. Messrs. Stanley Ashton & Co.'s exhibit of *Odontoglossum crispum* was elegant, more particularly the variety Ada, a giant white form some 4½ inches across (A.M.), and the splendid forms of *Cattleya Mossiæ*, such as southgatense, Harold, Princess May, also *Lælia purpurata* Russelliana with twenty-five flowers, and others. To each of the above three firms gold medals were well awarded. Messrs. Hugh Low & Co., who won the silver medal, had some delightful forms of *Cattleya Mossiæ*, more particularly one with white sepals and petals, with rich chrome throat with purple stain, and also received an award of merit for *Odontoglossum Andersonianum* albiflorum, extra rich spike, with faint crimson spots.

The groups of miscellaneous plants were quite in keeping with Manchester traditions, Messrs. R. P. Ker & Sons, Aigburth Nursery, Liverpool, having a boldly effective one, admirably arranged, and containing many choice plants for which the firm is noted. In addition to taking leading honours for their splendid group, Messrs. R. P. Ker & Sons were awarded the society's gold medal for extra excellence of plants. Mr. J. McIntyre, gardener to Mrs. Pease, Darlington, scored another decided success in his beautiful first-prize group, in addition to taking many prizes for specimen stove and greenhouse plants; while Mr. Upjohn, gardener to the Earl of Ellesmere, Worsley Hall, was second in this class.

Hardy Fruit Garden.

Thinning Wall Fruit.—Thinning the fruit of Apricots, Peaches, Nectarines, as well as other fruits, is an operation which gives good results, inasmuch as a limited number draws less upon the resources of the trees, especially as regards the formation of the stones in stone fruits. Where there are a large number of fruits it is evident that the stones alone must abstract a large amount of food from the soil, leaving less for the fleshy parts, which suffer in consequence. Hence the value of thinning is apparent, increasing as it does the bulk of fleshy substance and enlarging the fruits to a profitable size. Though, as a rule, thinning is carried out gradually, the majority of fruits which need removal may now be cut out. Exercise judgment in doing this, the rule being to leave a less number of fruits on weak, and a larger number on vigorous shoots. The ill-placed and malformed are always removed early. The final thinning consists of spacing out the best according to the strength of branches and shoots, and the general vigour and healthiness of the trees.

Regulating Wall Trees.—The young shoots of Apricots, Peaches, Nectarines, and Morello Cherries, which are to be retained for the future crop of fruit, ought to be disposed in vacant spaces, so that the growths may extend in the directions they are wanted and attain a sturdy character. The neglect of this at the present time results in many of the best shoots being spoiled by a crowd of superfluous growths which hinder the process of building up and finally ripening. In regard to Apricots, the reduction of the superfluous shoots may in many cases be turned to good account, as, for instance, well placed shoots growing in a foreright position. These may be shortened back to three or four leaves for forming spurs, instead of dispensing with them altogether. They, however, must not be crowded. At the same time nail or tie the young shoots close to the wall. Peaches, Nectarines, and Morello Cherries are chiefly refurnished each year with an ample supply of young wood, this being the best method for insuring good crops. Shortening shoots to form spurs is applicable to these as to Apricots, but it is not generally adopted. The annual shoots may be reserved much more thickly with the Morello Cherries than with Peaches and Nectarines. Choose shoots originating low down the branches, so that the base of trees may be kept well furnished. When the shoots are being first arranged with young trees it is a good plan to originate them on the upper sides of branches, establishing main branches at intervals to allow young shoots of medium length to be trained in.

Plums on walls are usually best if allowed to bear chiefly on spurs which are encouraged to form naturally or produced artificially by the summer stopping of foreright shoots. This stopping with Plums may be done now, leaving three good leaves. It will have the effect of plumping up the lower buds into blossom buds, though the upper buds may break into growth again. This can be checked at the first leaf. Old specimens are liable to lose branches, but if vacancies occur they may be filled by training in young growths, which will fruit the second season.

Cordon Gooseberries and Currants.—The branches of cordon trees are usually arranged at the proper distances, and therefore need no attention, but the growths upon them require some preliminary weeding out of useless twiggy growths, cutting them out at their origin. They prevent light and air reaching the base of shoots. Foreright growths issuing from the spurs are now advanced enough to be shortened back to three pairs of leaves. The process will admit light and air to the basal buds, and also help in the ripening of the fruit. Unless the leading shoot has reached its limit of space it should remain unshortened.

Watering Wall Trees.—The demands of wall trees at the present time for moisture are extensive. The base of walls is usually dry owing to the extra drainage and the difficulty of sufficient rainfall reaching the roots. Roots strike out in various directions to obtain it, often passing downwards into uncongenial subsoil, which causes sappy and rampant growth. Adequate moisture in the surface soil induces the roots to remain there, and they will do so if a liberal mulching of manure is employed during the summer season for the purpose of maintaining the soil uniformly moist.

Strawberries.—Immediately fruit commences to show colour, covering the beds with nets is important for the purpose of excluding birds. Beds with the fruit swelling and advancing to the ripening period may be copiously watered with liquid manure. Cut off all runners from newly planted Strawberries, also flower trusses. The formation of strong crowns the first season is very important. Destroy weeds by hoeing down the small seedlings, but fork up the strong specimens. Hoeing is not practicable when the beds are mulched, nor is it so necessary at the present time, as the manure keeps down the growth of weeds.

Fruit Forcing.

Peaches and Nectarines.—Early Houses.—When trees of the very early varieties, such as Alexander, Waterloo, and Early Louise Peaches, Cardinal, Advance, and Rivers' Early Nectarines have been cleared of the fruits, the shoots on which they were borne, if not required for the extension of the trees, should be cut away to allow light and air free access to the foliage. Syringe forcibly to cleanse the leaves of red spider, and if this and scale continue troublesome, the prompt application of an insecticide will be necessary to eradicate the pests. It is highly important that the foliage be kept healthy, and to prevent over-maturity of the wood or buds it is necessary to keep the atmosphere of the house cool by ventilating to the fullest extent after the fruit is gathered, excepting when the weather be unusually cold and the wood somewhat sappy. Keep the borders moist, and in showery weather remove the roof-lights. Keep gross laterals stopped, but avoid giving a check by a great reduction of foliage at one time, as this has a tendency to hasten the ripening of the growths, and when such is the case the trees will be swelling or casting their buds through over-development when they should be resting.

Trees of Hale's Early, A Bec, Rivers' Early York, Early Alfred, Dr. Hogg, Dymond, Stirling Castle, Royal George, Grosse Mignonne, Noblesse, and Bellegarde Peaches, with Lord Napier, Rivers' Orange, Stanwick Elruge, and Humboldt Nectarines, in the same house, will be ripening their fruits, and must not be syringed unless the trees become infested with red spider. When water hangs on the fruits for any length of time after they commence ripening the skin is liable to crack and the edges of the fissures are soon attacked by a mould, which imparts a musty flavour. The trees must not be allowed to suffer by want of water at the roots, but any excess of moisture at this stage has a tendency to cause splitting at the stone.

Houses Started Early in January.—Where the trees have been forced for several years consecutively they will have the fruit in the condition described in the preceding paragraph, but where they are forced for the first time, or have been forwarded gently, the earliest fruits will now be ripening. The leaves should be turned aside, and the fruit raised on laths placed across the wires of the trellis and secured with its apex to the light. This, however, ought to have been effected some time ago, and the fruit will, where it was done, now have attained a good colour. If the weather prove dull and wet gentle fire heat will be necessary to secure a circulation of air constantly, the temperature being maintained at 60° to 65° at night and 70° to 75° by day. Cease syringing as soon as the fruit begins to ripen or soften, and take care to have the foliage free from red spider before the syringing ceases, or the pest will increase so rapidly whilst the fruit is ripening as to seriously jeopardise next year's crop. There must not be any deficiency of moisture in the border, and, if necessary, give a thorough supply of water, mulching with about a couple of inches of light, rather lumpy material, such as Mushroom-bed refuse or partially decayed stable litter.

Succession Houses.—During the stoning process the trees must not be hurried or it may be fatal to the crop, therefore allow time for this most important point. Allow a free circulation of air, ventilating early in the morning, and close in the afternoon with an abundance of atmospheric moisture, so as to raise the heat to 80° or 85°, and ventilate a little afterwards for the night, the temperature being allowed to fall to between 60° and 65°. This must only be practised after the stoning is completed, as a close atmosphere has a tendency to promote growth, which is not favourable to that process, therefore avoid undue excitement when the trees are in that condition. When the fruits have stoned remove all surplus fruits, and turn the others with their apexes to the light to insure colour and even ripening. Allow a rather free extension of the laterals as an encouragement of root action, but be careful not to crowd the principal foliage, and keep red spider in subjection by syringing twice a day. Give thorough supplies of water through a surface mulching not more than a couple of inches thick, of lumpy material, and supply weakly trees with liquid manure. Vigorous trees will not need more than a surface mulching, as high feeding will only cause grossness, and must be studiously avoided.

Late Houses.—Train and tie in the shoots that are to carry next year's crop, allowing them to extend to a length of about 15 inches or more if there be space, or stop them at about that size and pinch laterals to one leaf, being careful to avoid overcrowding. Young shoots required for extension or furnishing the trees should be allowed to extend as far as space admits, and pinch all side shoots on last year's extensions that are not required for next year's fruiting or furnishing the trees, so as to form spurs and secure an equal distribution of the sap.

In thinning the fruit leave a few more than will be required for the crop. A Peach to every square foot of trellis covered by the trees is ample to secure the finest specimens of the large fruited varieties; the medium sized and Nectarines may be left a little closer. Keep the leaves clean by syringing twice a day, and always sufficiently early to allow the trees to become dry before night. If insects cannot be kept under by these means promptly apply an insecticide. Mulch the borders with a little short manure, or if the trees are young and vigorous lighter and less rich material will be more suitable. Water thoroughly whenever necessary, always giving sufficient at a time to reach the drainage. Ventilate early and increase the ventilation with

the sun heat, closing early in the afternoon. If the fruit is wanted late, however, keep the atmosphere as cool as possible by free ventilation day and night.

Recently Planted or Young Trees.—In the training of these disbudding plays an important part. Leave the main branches or shoots for forming them 15 to 18 inches asunder, and the bearing wood at a similar distance on the last and previous year's wood, training the extensions their full length, and pinching the side shoots on last year's wood that are not required for bearing or extension to two or three leaves, so as to form spurs, but do not overcrowd the trees with foliage. These stubby shoots often give good results whilst the trees are young, setting and stoning the fruit better than is the case on strong young wood. Pinch laterals at the first joint, and successional growths as made. Avoid exciting too vigorous growth by the use of stimulants, employing nitrogenous manures sparingly, and an excessive supply of water at the roots, but employ phosphatic manure with a firm soil, so as to secure a free fibrous root formation, and sturdy, short-jointed, thoroughly solidified wood.

THE BEE-KEEPER.

Extracted Honey.

IN many districts run, or extracted honey, is in greater demand than honey in the comb. Where this is the case bee-keepers should lose no time in making arrangements for obtaining a surplus. One fact should always be kept in mind—namely, the stock having the greatest number of worker bees will store the heaviest weight of honey. For this reason it is an advantage to encourage the bees to commence breeding early in the spring, and should the weather be cold give them the necessary attention as advised in previous notes. The present season has been most trying to the bees, and many colonies are still weak. It is, however, surprising how those stocks have improved in strength which received timely attention.

No one can deny the fact that in an apiary where several stocks of bees are kept there will always be found some that are weaker than others. If we work solely for a surplus, and attempt to obtain supers in whatever form they may be used, from each individual stock it will be found that the weaker colonies will only have reached the desired strength when the honey flow is over. There will thus be a waste of energy on the part of the bees in the weak stocks, and there being no system of rearing young queens they would gradually become weaker from this cause alone. Shallow frames are excellent for obtaining a good sample of run honey, but, as in the case of placing a crate of sections on a hive, care must be taken that the stock is well crowded with bees. If they are not of the desired strength, and honey is coming in freely, a frame or more of hatching brood with the adhering bees may be taken from another colony to strengthen it. If this is done during the middle of a warm day no harm will accrue, as the other bees will take readily to them.

Using Full Sized Combs.

We have invariably obtained the greatest weight of honey when full sized combs have been used. Probably the system on which they are worked has something to do with it. By using the standard frame for extracting purposes we are enabled to build up immense colonies, which will take advantage of a few hours of bright sunshine to store a surplus. Were these bees distributed between two or three stocks a much less quantity would be stored. The plan we adopt is to select a given number of stocks from which it is intended to obtain a surplus. These are all headed by a young fertile queen reared the previous year. We then examine each stock, and select three or four frames of the most forward brood, care being taken not to remove the queen. The vacancy is filled up with frames of fully drawn out worker comb or foundation. This will be the means of keeping the queen fully employed. A piece of queen-excluder zinc is then placed over the top of the frames, which will confine the queen to the brood chamber.

A separate box should then be put on the top of the hive to form the super. If made of the right dimensions it will hold nine frames, which are placed wider apart than when used in the brood nest. This super is filled with the combs taken from the brood chamber, and the frames and adhering bees procured from the weaker stocks. These should be placed alternately. The bees need not be sprinkled with syrup or flour, as at this season no fighting will take place, and only the old bees will return to their original stock. It is not necessary to fill the super with combs containing brood, as we always use a large proportion of clean combs, reserved from the previous season. These must always be placed on the outside of those containing brood. This operation should be carried out at least a fortnight before the honey flow is expected.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

•• Grapes Scalded (R. A. C.).—The berries are not shanking but are scalded, which appears rather common this season and at an earlier stage than usual, occurring when the Grapes are about half swollen. A few berries are affected here and there in some cases, but in others the whole side of the bunch or bunches is damaged. We have known instances of nearly two entire crops being lost owing to this, the berries being completely destroyed as if scalded or parboiled. It is caused through late or imperfect ventilation on some bright sunny morning, whilst the internal atmosphere and even the berries are saturated with moisture. The only preventive is earlier ventilation, a little air being left on constantly at the top of the house, and maintaining a gentle warmth with hot water pipes so as to maintain a circulation of air.

Will Ivy or Ampelopsis cause a Skin Irritation and Eczema? (F. C.).—See p. 483, "The Poisonous Sumach." The smell of Ivy freshly cut affects some persons by its unpleasantness, though the leaves really have a balsamic odour, especially when bruised or rubbed, and probably the odour pervades the system, giving rise to cutaneous affections. Indeed, the bruised leaves have been applied to corns, and the fresh ones for dressing ulcers, while, in the form of decoction, they have been recommended in sanious ulcers and cutaneous eruptions. We have also known clippers of Ivy suffer considerable irritation of the skin, which in some cases arises from the mites present on the Ivy and their getting on the human skin, the mites sometimes causing almost intolerable itching. Apart from the mites, the dust set free in the action of cutting the Ivy causes serious irritation of the skin in some cases, whilst in others the dust gives rise to little inconvenience. Of the properties of Ampelopsis we have no knowledge of any ill effects arising from it when worked amongst by gardeners. Your specimen was a Rhus; see "Readers' Views," page 483.

Cattleya Culture (Orchid).—The plants should not grow again the same season, as this weakens them, the important point being to secure a good growth and then give a long period of rest. During the growing season Cattleyas like a genial, moist atmosphere, and an abundant supply of water, which should be administered from the watering can, for in the case of those grown in pots, it has been frequently remarked that, where regularly syringed, they neither grow nor flower so well. Plants on blocks may be syringed, as there is no danger of the water lodging in the large sheathing scales which envelop the young growths. Of course, those on blocks should be taken down during growth two or three times a week and immersed in a tub of water not less in temperature than that of the house. After the pseudo-bulbs are formed, water must be withheld, and the plants allowed a season of rest, but care should be taken to prevent their becoming exhausted during this period, as much injury may arise if the withholding of water be carried to excess. A long season of rest will cause the plants to flower more freely, and to grow more vigorously afterwards. They do not require manure of any kind, a compost of good fibrous peat from which all the gritty part has been well beaten, and chopped living sphagnum with some clean, sharp silver sand supplying all their requirements. Thorough drainage is most essential, letting the plant sit upon the top of the compost, this being elevated somewhat above the rim of the pot, in order to carry away the water quickly. Oncidium Marshallianum requires the same temperature as Cattleyas and similar treatment, taking care not to allow shrivelling of the pseudo-bulbs.

Diseased Tomato Plants (N. Y. Z.).—An article dealing with this subject will be found on page 489.

Rhododendron cinnabarinum (J. F. S.).—This Rhododendron, of which you forward a flowering shoot, is a sub-evergreen Himalayan species, which is not generally regarded as perfectly hardy in this country. These two facts will readily account for the annual loss of a number of the leaves; possibly in a colder aspect, and with the roots in a damper soil, the plant would succumb to the severity of the frosts.

Spraying Engine (E. Newport).—We have no knowledge of the spraying engine to which you allude being used in this country. There are several excellent machines on the English market, some of which are for large cultures, and travel on a wheeled carriage; others are in the form of a knapsack, to be strapped to the shoulders of the operator; while still smaller we have the "Abol" syringe, which diffuses as complete and fine a spray as can be desired for any purpose.

Ledum palustre (W. Ruby).—Wild Rosemary is one of the popular names by which that pretty little North American shrub Ledum palustre is known, a title which has probably been conferred upon it because the foliage possesses a powerful aromatic odour that is particularly noticeable when the leaves are crushed in the hand, or immediately after a shower on a warm day. In other respects it is widely separated from the true Rosemary, and is a close ally of the Kalmias and Rhododendrons, which are so well known and appreciated in gardens. It is a compact shrub, rarely exceeding the height of 3 or 4 feet, and

FIG. 132.—LEDUM PALUSTRE.

bears small, narrow, elliptical, dark green leaves, and close corymbose racemes of white flowers, which are freely produced and render the shrubs very attractive in summer. They are especially suited for planting in the front of shrubbery borders, and being evergreen their neat habit renders them attractive at all seasons. Moderately light soil is requisite to obtain them in the best condition; but they are not very particular, and if the border is well drained little difficulty will be experienced with them. Both *L. palustre* and *L. latifolium*, also known as Labrador Tea, possess some medicinal and economic properties. The former is said to contain qualities which render a decoction of the leaves beneficial as an external application in cutaneous diseases, and in some parts of Germany a peculiar kind of beer is also prepared from the leaves. *L. latifolium* is considered to possess tonic qualities, the leaves having been employed to furnish a substitute for Tea, and they are also infused in beer, which they render heady, and cause headache, nausea, and even delirium. *Ledum palustre* (fig. 132) was admirably shown by Messrs. J. Waterer & Son, Ltd., Bagshot, at the Temple Show.

Succession of Lilacs (H. S.).—Though there are no particularly late varieties of Lilacs, the following are very fine, and give a good display of bloom in May and June: *alba grandiflora*, white; *alba magna*, white; *alba virginalis*, white; *Alphonse Lavalle*, sky blue, shaded with violet, double; *Charles X.*, deep purplish lilac; *Dr. Lindley*, reddish lilac; *Le Gaulois*, dark peach colour with light centres, double; *Lemoinei*, pale ashy lilac, double; *Mathieu de Donbasle*, reddish mauve, double; *Michael Buchner*, pale lilac, rose margined, double; *ranunculiflora*, dark red, becoming lilac, double; *Renoncule*, azure-mauve, double; and *rubella plena*, vinous red changing to rosy violet, double. To these may be added the Persian, *Syringa persica*, and its white variety *S. p. alba*.

Covering Bank Above Tennis Lawn (S. R.).—We are obliged by your further information that Rose Fellenberg is grown at the top of the bank. It will be better, therefore, to keep to *Sedum reflexum*, as *S. spurium coccineum* will not answer when associated with the colour of that Rose. If you like, you could, however, have a band of *S. spurium coccineum* at the base of the bank, the remainder being covered with the other. They flower about the same time, but *S. spurium coccineum* is dwarfer than the other, and is thus unsuitable for a centre. Seeds of it can be procured from Thompson and Morgan, Ipswich. Very small pieces of either inserted in sandy soil and watered would soon take root and form good plants.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. F. S.).—*Rhododendron cinnabarinum*, see page 494. (D. R. W.).—1, *Halesia tetraptera*; 2, a *Doronicum*, but the flowers were quite dead through the package being in the post over Sunday; 3, 4 and 5, were apparently all forms of *Azalea mollis* which probably never had varietal names. (N. S.).—1, *Polypodium vulgare elegantissimum*; 2, *Pteris umbrosa*; 3, *P. serrulata cristata*; 4, *Asplenium bulbiferum*; 5, *Cyrtomium falcatum*; 6, *Pteris tremula*. (B. W. E.).—1, *Coprosma Baneriana variegata*; 2, *Hydrangea Thomas Hogg*; 3, *H. Otakura*; 4, *Cytisus Atlecans*; 5, *Ornithogalum umbellatum*, the Star of Bethlehem; 6, *Spiraea media*. (A. J.).—Only three specimens enclosed. 1, *Thunia alba*; 3, *Dendrobium thyrsiflorum*; 4, *Asphodelus luteus*. (R. C. N.).—1, *Piptanthus nepalensis*; 2, *Spiraea hypericifolia*.

Sheep and Shepherds.

THERE is so little land in Great Britain that is unsuitable for the breeding or feeding of sheep, and the animal has been such a help to the British farmer in his struggle to keep his head above water, that everything connected with the sheep is of the greatest possible interest.

It is time now that the sheep dispensed with his warm coat, and all over the country the shears are hard at work, whilst we hear the pitiful bleatings of the lambs anxiously seeking for their mothers in the crowded pens, and often finding mamma hardly recognisable, such a change has the clipping made in her outward appearance. When ewes are being clipped it is a good plan to turn them out to graze for a couple of hours during the evening after clipping is over, and then bring them up again into a dry yard for the night. They will be less likely to get a chill, which so often results in a case of downfall in the udder, one of the most awkward complaints which a shepherd has to deal with. A heavy dose of salts and rubbing of the udder with goosegrease are the chief remedies, but they are only of use if the attack is discovered in its incipient stage. Of course the milk must be drawn, as it would not be suitable for the lamb if its mother would allow it to suck. If the ewe be in anything like good condition the best remedy is the butcher's knife. If she recovers it will be very unlikely that she will be of any more use for breeding purposes, and if killed at once the carcase is excellent food, and will realise a fair price.

Very soon after the clipping the flock should be dipped, or at any rate the lambs must be, and the ewes watered with the solution at the same time, but we prefer to dip all. The ewes newly clipped require to be in the bath a few seconds only, and the operation takes less time than the watering, and is more effectual. This dipping of sheep is becoming a very important matter to the agricultural interest, as there is little doubt that many, if not all, outbreaks of sheep-scab, are due to neglect in this important matter.

At the present time there is considerable agitation in favour of making dipping compulsory, and as it is such a very necessary operation and one so identified with the interests of the flockmaster, it is difficult to see where sound objections to such compulsion could be discovered. One very necessary part of any Bill which may be brought before Parliament to enforce dipping ought to be compulsory registration of really effectual dips. No dip should be allowed for official purposes which has not been tested and certificated by the Board of Agriculture. There will naturally be supervision of dipping by the cattle inspectors now acting, and they will take samples and check the quality of the dips which they find in use. They will thus do something to earn the salaries which they receive and for which some of

them now do very little. It would be a splendid thing to inaugurate such a system of dipping as would make an outbreak of sheep-scab a practical impossibility. Nowadays farmers are very much at the mercy of inspectors, and only very lately a farmer in the north was fined for not reporting an outbreak of scab, which on appeal was proved by a high veterinary authority not to be scab at all. We have ourselves had personal experience of a similar case.

The sheep is an animal of such great adaptability and varies so much in the character of its different breeds that success in sheep breeding and grazing depends almost altogether on two points: 1st, the selection of the most suitable breed for the soil and climate; 2nd, the proper and intelligent management of the flock when chosen.

It is a curious fact, but it has been noticed by many observers, that the owner of a small flock enjoys very good fortune with his sheep. He generally has a good fall of lambs, has few casualties, and his mutton sheep are usually bigger and fatter than those of his neighbours. Some people account for this by stating that the small flock is often numerically weak in proportion to the size of the holding, and that sheep when run thin on the ground invariably do well. There is much truth in this, but we think that a more sensible way of accounting for the success of the small flockmaster is to acknowledge the fact that he gives more individual attention to his sheep; he looks after them himself, having a personal interest in the welfare of each; his shepherding is not done by the hour; in summer he is looking round the sheep before six, so that he may be ready for ploughing at the usual time, whilst the evening again sees him looking over the flock. Too many of the paid shepherds make the day a short one, and the night a long one, and we know by experience that the morning shepherding brings to light many more cases of illness than the evening. The shepherd has to face all kinds of weather, and in storm and snow he must rough it, no doubt, but generally speaking his work is not heavy and he ought to keep both early and late hours if he does his duty in the endeavour to earn the very good wages which his services usually command.

The prevention of lameness is one of the chief points, success in which marks a man as a good shepherd. It is much easier to prevent lameness than to cure it. Many, too many shepherds, neglect looking over their sheep's feet at sufficiently short intervals; of course these periods vary according to the weather and the character of the lair. They think it soon enough to examine a sheep's feet when it is turning lame, whereas if that sheep had been looked at two or three weeks before a very slight use of the knife and application of ointment would have prevented the lameness altogether. It is a remarkable fact that some shepherds, and also some farmers who are their own shepherds, are very little troubled with footrot amongst their flocks. We do not attribute this immunity so much to the soil or locality as to the reasons we have just explained.

The most anxious time of the year for the sheep breeder is the period of two months after weaning. Unless he is prepared with plenty of change of food for his lambs and ample field room for them after they are parted from their dams there is often serious loss. Cabbage, Clover-eddish well grown, well gleaned stubbles, and well matured Rape and Tares, are all capital things to ring the changes on. We have found well hearted Cabbage drawn off and fed to the lambs on old seeds until stubbles are ready, to be as safe and successful a food as any, and a good education for Turnips.

Work on the Home Farm.

Warmer and more summer-like weather has given all vegetation an altered appearance. Wheats are running up fast, and both Barley and Oats have made good progress. We have had one nice rain, but could do with more, as sun and wind have dried the surface soil rather rapidly.

Turnip sowing is proceeding generally, and the seed is going in well, in fact as well as it could do, and in marked contrast to last year when the land was in such a sodden condition. We have no doubt farmers will push on with sowing as fast as possible. Unfortunately

where manure has to be got on for the Swedes the labour difficulty is proving a hindrance. The filling, carting, and spreading of farmyard manure is the heaviest item of labour on a farm. There is a great deal of manure still to get out, and few hands to do the work.

The late frosts affected field Peas adversely, and put them back a little, but they have grown well lately and will soon be in flower. Another nice warm rain would do them much good.

Potatoes are coming up, and many fields are ready for horse-hoeing. Some that were put in early, before the land had thoroughly dried after the wet February, are inclined to be heavy and short of mould between the ridges. A good chisel-toothed horse hoe or grubber must be used to thoroughly break up this soil, as it is of no use earthing Potatoes with half bricks. Potatoes are coming up very regularly this year, there being few gaps or backward plants. This will enable the farmer to get them earthed in good time. Now is the time to apply the top-dressing. We strongly recommend sulphate of ammonia, 2 cwt. to 3 cwt. per acre, as is thought desirable according to the nitrogen required. The hoeing must be got through as soon as possible, weeds are more easily chopped out when small, and the young fibres and forming tubers of the Potatoes less liable to injury by the hoes than if the hoeing is postponed until the tops are stronger.

There has been better luck with the later foals, and we see some nice ones about. As it is found convenient to work the dams a little during the pressure of Turnip sowing, care must be taken not to separate the mare and foal for too long a period, especially in hot weather.

Foot-and-Mouth Disease.—We regret to hear of a fresh outbreak of foot-and-mouth disease at Welwyn, Hertfordshire. Fortunately, only two cows and a bullock were affected, and these were at once killed off. It is supposed the infection was carried by an animal bought at Hitchin Market, but there is not the slightest clue as to how the disease came into the district. The Board of Agriculture have issued an order prohibiting the movement of stock within a large area.

Imports of Eggs.—A Bill has been introduced into the Canadian Parliament providing that all eggs intended for export shall be sold by weight, and that the standard shall be 1½ lbs. per dozen, or 2 ozs. each. It does not apply to the local sales of eggs. This is but one instance of their determination to capture the English market by giving them such goods as they want. We do not think, says a contemporary, selling by weight is any more equitable than selling by number, unless it is determined what proportion of the egg be shell and what shall be meat, but if buyers want them so, why, produce the heavy eggs.

Exhaustion of Land by Oats.—There are two reasons why the Oat crop is exhaustive. One is that its grain contains more of the mineral and nitrogenous elements that are needed by crops than any other grain except Wheat. Besides, the Oat plant has to grow from the germ, ramify its roots through the soil and search out this plant food within the short space of 110 to 120 days. Winter Wheat makes a start in the autumn, then goes into its winter sleep under a blanket of snow or fast locked in frozen soil, and it is then ready to make further growth in soil mellowed by winter's freezing, and therefore having more of its mineral plant food available for present use by any roots that are on hand at the right time to take it up.—("American Agriculturist.")

Dairy Notes.—At the Cornell Experiment Station they tried making cheese from milk containing various proportions of butter fat, and they found that of milk with 3 per cent. fat 100 lbs. made 8·67 lbs. of cheese. That with 4 per cent. fat made 10·8 lbs. of cheese to the 100 lbs. of milk, while of 5 per cent. milk there was 12·6 lbs. of cheese to the 100 lbs. of milk, and a milk with 6 per cent. fat made 14·6 lbs. of cheese to the 100 lbs. of milk. While the increase was not in exact proportion to the amount of butter fat in the milk, it shows at least that 6 per cent. milk makes 70 per cent. more cheese than 3 per cent. milk. This furnishes as good a reason why those who take their milk to cheese factories should be paid higher prices when the milk is rich in butter fat, as there is that they should when they take it to the creamery. And we would wager a large Apple that the cheese made from the 6 per cent. milk was much the best cheese of the lot when properly cured; and another, that the cheese made from the 3 per cent. milk was not much better than some of what are called partly skimmed cheese.

A Triumph in Hybridisation. . Unique Offer.

3 NEW PASSION FLOWERS ALL DISTINCT.

Exceeding in beauty all others. Delicately Perfumed. Free Blooming.

Raised at Oldfield Nurseries, Altrincham.

PASSIFLORA CLIBRANI.

This beautiful distinguished hybrid cannot be too highly commended. We claim it to be the ideal of all the Passion Flowers, it being a most distinct and handsome variety after the style of Princeps, but far excelling this variety. The petals are of a rich red wine colour, always so attractive, rays of corona chocolate tipped with white. A charming flower in every respect. Perfectly free and vigorous.

PASSIFLORA FRAGRANT BEAUTY

As the name truly implies, this variety possesses a fragrance perhaps exceeding that of any other variety. A plant now in bloom at our Oldfield Nurseries commands the admiration of all visitors on account of the delicious perfume. The petals are pure white, rays of corona in two circles, centre chocolate brown, zoned white in the middle, upper portion bluish purple shades. Charming contrasts. Profuse bloomer.

PASSIFLORA OLDFIELD GEM.

This excellent hybrid possesses very considerable merit. It is a distinct handsome and free variety. The flowers are very large, and what has been said of the perfume of Fragrant Beauty we reiterate respecting this magnificent gem. The petals are pure white, delicately netted rose. The rays of the corona are in two circles, and being of a wavy outline they greatly enhance the appearance of the flowers. Centre rich velvety maroon, clear white zone, upper portion purplish violet.

Price 2/6, 3/6 & 5/- each; the set of three, 6/6, 9/- & 13/-

Drought and Watering.

THE question of watering has already forced itself unpleasantly to the front, and there is every prospect of the season being an abnormally dry one, with the usual accompaniment of languid vegetation and insects in legions. The experience

of past droughts leads one to delay the application of water till the latest moment in the hope that long expected rain may solve one's difficulties, and at the same time re-invigorate vegetation in a manner that no method of artificial irrigation can quite equal. On the other hand, if it is decided to apply water, as in many cases, especially in closely planted flower beds and borders, is it necessary to do, then it is, to say the least, injudicious to delay doing so till the soil has become overdry—so devoid of moisture as to check growth. By watering sooner growth is continued in a healthy condition with a smaller expenditure of labour and of water than it requires to preserve plants from going from bad to worse. It is obvious, however, that local conditions must largely determine whether it is better to water early and continue watering or to delay in the expectation of rain.

A generally well known phenomenon accompanying irrigation is the comparatively poor progress apparent in those crops that are regularly watered in drought. The soil may be preserved fairly moist, and the plants still exhibit symptoms of malnutrition, so much so that not a few people hesitate on this account to seek a panacea in the hydrant and hose. The results are indeed somewhat similar to what is seen to follow a period of continued wet, and what is familiar in the case of pot plants that are grown for a long time in the same soil and pot without receiving anything but pure water. At the very best, water by itself, if it does no harm, effects no lasting benefit, and all experience goes to demonstrate the need of some simple easily assimilated manurial agent being employed in conjunction with it.

There is nothing novel in this. All thoughtful and

observant cultivators, past and present, have practised in some shape or other a system of manure watering in preference to employing pure water other than in emergencies. The manure may be laid on the surface of the ground, and absorbed into the soil with moisture, or it may be applied directly as a solution either of animal excrement or of some easily soluble chemical matter, as superphosphate of lime; but in whatever form the results are invariably of a like nature, vegetation neither declines nor stagnates, but continues to make effective progress. It may be desirable to submit a word of warning not to overdo manure when it is seen that water may be required repeatedly at short intervals of time. As a matter of fact very slight additions of manure are required to effect the purpose in view, the simplest material, superphosphate, dissolved to the amount of 1 ounce to 50 or 60 gallons of pure water, being amply sufficient to preserve vegetation in vigorous health. Pigeons' manure sown thinly on the surface is next in value and usefulness to the above named, and of course where hose watering is practised all manures must be applied directly to the soil. On this point I will only add that the importance of adding manures to water can be scarcely overestimated.

It is so generally recognised that soil cultivation exerts an influence, perhaps incalculable, on the conservation of moisture that it would appear superfluous to do more than allude to it. There are, however, one or two points that are worth elucidating, and which, as it appears to me, are to a great extent overlooked. We are all agreed on the point that deep stirring—trenching—soil is of first importance, and that the more perfectly soil can be pulverised so much the more fertile is it bound to be. But it is sometimes forgotten that these operations tend to looseness, which, uncorrected by compression while the soil is dry, is a condition by no means to be commended.

Some years ago, while inspecting the garden of an ultra-trencher, we discussed a long flower border which annually trenched, at the time in question was daily watered and seemed to need the treatment. I tried the penetrating power of my stick in the soil, and it went down to the bottom with little beyond a gentle push, indicating the suppressing of all attempts at firming, and the reason for the unremitting attention to watering. In pot culture we are no doubt more advanced in our practice as regards soil compression than in garden culture, and the same remark applies to fruit tree borders. But flower beds and quarters of vegetables should be treated in much the same manner, when it will be found that the power of the soil to conserve moisture has been thereby very greatly increased, with the further advantage that in this condition less water is required to moisten it when it becomes essential.

The management of manure and methods of application have also not a little to do with the question of watering and its necessity. Gardeners are unfortunately largely the creatures of circumstance with regard to the quality of the manures supplied for their using, but the control of its application is entirely in their own hands, and, as a rule, its value as a conserver of moisture is much enhanced when it does not lie for a long period in the ground previous to the crop being put in. It is also important that it be well incorporated throughout the soil, and within easy reach of the roots, while beyond all that it should be well firmed with the soil. Treated in the way above indicated a properly manured soil forms a long standing reserve of moisture, which in many cases will carry a crop over a lengthened drought without the necessity of resorting to the watering can.

Another distinctly advantageous way of garden management is to plant out comparatively small stock during dry weather in preference to that which is large. Waiting for rain is no doubt largely the reason for all kinds of vegetables to be transplanted being allowed to remain in seed bed or where pricked out till they become over-large. Experience proves that a small, healthy, well rooted plant set out in the afternoons of hot weather periods, and started with one application of water, will at once take hold; while larger plants require much water, and do not succeed in the end so well as the smaller, which has involved less labour in its culture. The value of surface hoeing and of mulchings has so often been discussed, that it is unnecessary to do more here than mention them as essential.—B.

The Fruit Prospects.

THERE can scarcely be two opinions as to the coming season's prospects, at any rate in the southern and western parts of England. What may come from eastern and northern counties is not yet much known to those resident in the west, but no doubt evidence will soon be furnished bearing on that point. Gooseberries, the earliest of British fruits to be used in a green state, are said to be everywhere abundant, and this is reported from the largest market, so that all counties are presumably favoured alike. Even in Gooseberries there are exceptions, for in my own case there are many trees bearing scanty crops, while others are fully laden, proving that the same frost resistance is not given to all alike, and frost, though not severe, occurred at the flowering period. All were full of promise at that time, and appeared so for a little while after, but further examination shewed stationary and falling berries in goodly numbers. One of the worst offenders in this respect was Whinham's Industry, and of this I have a fairly large number of trees, some young, others old, but all carrying light crops. Others are most satisfactory, and the berries at this early date seem larger than usual.

Strawberries in the winter, and until the flowering period was advancing, made a very indifferent promise, but later the flower trusses have developed wonderfully, and have been a sheet of blossom. Even small late planted runners are making a surprising effort to fruit, and their present condition could not have been estimated early in the year. In other gardens I saw a week ago very fine leaf growth and promise, and felt disappointed in the comparisons drawn between beds here and those inspected elsewhere. That feeling, however, has to some extent subsided, and give favourable weather I am of the opinion quite as good a Strawberry crop awaits us as in previous years.

Peaches and Apricots outdoors are, and have been, so profusely set that severe thinning has been resorted to, and will need still further attention, Apricots in particular being very thickly clustered. The weather, though far from genial, was free from frost during blossoming time. Ripened wood brought about by the tropical sun of last summer and autumn, and the subsequent heavy rainfall, tend largely towards this satisfactory prospect, and this applies to all other open air fruits, many of which languished for want of root moisture last year. The amount of energy distinctly visible now is scarcely credible when reflection is made on wilted and suffering tree and Strawberry growth in the previous year. There must be a great power in the winter's rain in restoring impaired vitality.

Apples generally are well fruited, though some that bore freely last season flowered more thinly this. This is a trait, however, common to many sorts—alternate years of fruit and scarcity. Cockle's Pippin, Court Pendu Plat, Hoary Morning, and King of Pippins are instances where dearth follows plenty. Many others are so thickly set that severe thinning must of necessity arise. Fearn's Pippin, Mannington's Pearmain, Cox's Orange Pippin, Beauty of Bath, and Frogmore Prolific are densely crowded with swelling fruits. Pears are more uniform—that is, viewed from their present appearance.

The more precocious of the Plums happened to meet the same fate as Gooseberries, but those later in bloom escaped injury. On the west wall there is a much heavier crop than on that opposite—east. On the latter aspect the trees were earlier in bloom when slight frosts occurred to damage them. Washingtons on both aspects present a striking difference in their crops—one needs severe thinning, the other is very sparse in fruit; the same difference appearing between Oullins Golden on a west and south wall. Cherries, both dessert and Morello, are crowded with fruit on the walls, and standard trees promise bountifully. For the past eight years I have not seen such freedom in outdoor Figs as this season. Quinces and Medlars, standard Plums and Damsons, all vie with each other in flower production. Red and White Currants will be plentiful, and in some gardens Black also; but there are cases where these are not so freely cropped. Raspberries look well, and there should be a record crop.—W. S., Rood Ashton.

Phaius bicolor as a Stove Plant.

SPEAKING generally the Orchid family is as accommodating as it is interesting and varied, and its increasing popularity may to a large extent be attributed to this fact. The time was when Orchids were generally understood to be aristocratic flowers, costly to begin with, and requiring much skill and money to cultivate them successfully. Partly owing to the efforts of collectors and tradesmen in bringing plants down to popular prices, and partly to increased knowledge on the side of growers, Orchids no longer occupy isolated positions in the establishments of a few. They are to be found everywhere, and many an amateur with only limited glass accommodation, who does the work himself, has reason to be proud of his little collection of Orchids.

It is not the specialist alone who has done so much to popularise the Orchid family, for there are numerous establishments, large and small, the owners of which have no pretensions to be what are called enthusiasts, and yet they like to have a few Orchids. These are not the places to look for new and rare plants, for hybrids of surpassing beauty, and specimens unique on account of their scarcity; but it is in establishments of this kind where plants of well-known forms are frequently seen blooming profusely in mixed collections of stove and other plants. Sometimes it is a *Dendrobium*, sometimes a *Cattleya*, a *Cypripedium*, *Odontoglossum*, or what not; and though admiration may be confined to a limited few, these solitary specimens, grown among miscellaneous plants, are a source of extreme pleasure to owners, pride to gardeners, and illustrate beyond argument the accommodating nature of the great Orchid family.

The illustration (fig. 133) is a case in point. There is nothing extraordinary about *Phaius bicolor*. It is a well-known form of what may be classed as a somewhat neglected family. It possesses none of the gorgeous beauty of some of its relatives, and its range of variety is much more limited. And yet the *Phaius* is a charming Orchid. It tolerates the conditions of the ordinary stove, and flourishes in the company of the general occupants of such structures. But it will not brook neglect, and more than once I have seen specimens, half-hidden away in odd corners, only failing because they have never had a chance, and yet too tenacious to give up life altogether. These are not pleasant phases of mixed Orchid culture; but when one sees plants such as that shown in the engraving, it is another matter, and one realises that *Phaius bicolor* is a plant well worth growing.

A glance at the accompanying picture shows a healthy well-grown plant with spikes nearly 3 feet high clothed with a wealth of flowers, all illustrative of good culture. Yet this plant was grown in no

special Orchid house, but in a shady part of the stove in the garden of F. H. Cook, Esq., The Grange, Walton-on-Thames. About its treatment Mr. A. Haynes, the gardener, has no long tale to tell, but his remarks are pointed and practical. An 11-inch pot accommodates the specimen, and it revels in its compost of loam, peat, and sand. The tall spikes and large flowers were doubtless built up by frequent applications of liquid manure when the blooms appeared, and the healthy young growths promise well for the future. In short, it is a fine specimen of a well-known plant grown in a mixed collection, and both Mr. Cook and his gardener have every reason to be proud of it. —G. H. HOLLINGWORTH.

Cambridge Lodge.

METROPOLITAN Orchid enthusiasts are now very numerous, and it is pleasant to know that there are yearly accessions to the ranks. Amongst those whose names have become familiar over the entire Orchid-growing world is R. I. Measures, Esq., Cambridge Lodge, Flodden Road, Camberwell, who has for many years been improving his collection, as well in quality as in quantity. Generally speaking amateur growers devote the major portion of their energy on one or two sections, and what others are grown are simply tolerated, and are not regarded as worthy of any special attention. In Mr. Measures, however, we find an enthusiast in the broadest sense of the word, whose love for Orchids embraces every kind, hybrid and variety, large or small, modest or ornate, that can be found room for in his wonderful London garden. And yet as one inspects the several houses, one is forced to the conclusion that here we have a general specialist, for the *Masdevallia* collection is probably unique as regards species, the *Cypripediums* are superb, the *Cymbidiums* lack practically nothing, and so on through practically the entire Orchid family.

The Cambridge Lodge Orchids have been written of in the pages of the *Journal of Horticulture* on several previous occasions, but to render honour to one of the chief Orchid growers of the metropolis, or, indeed, of the United Kingdom, they may be again referred to.

We can, too, at this moment pay a tribute to Mr. Measures' kindness in allowing all interested to see and admire the beautiful plants he has gathered together with such assiduous care and at such great expense. Thus others can enjoy the sight of many thousands of Orchids in various stages of growth, from the newly vegetating seed to the stately specimens that are alike in only one respect, and that is the excellent state of health. Even as Mr. Measures' tastes in the matter of Orchids are omnivorous, so, too, are apparently Mr. H. J. Chapman's abilities as a cultivator, for one and all are in such condition as must be gratifying to all those immediately concerned in their growth, and is matter for surprise to all visitors to Cambridge Lodge.

When one considers the difficulties that stand in the way of successful Orchid culture in such a densely populated district as Camberwell, and then sees not one, but hundreds of plants that have been there for ten years or more, or have been raised there from seeds, one becomes more and more astonished. We do not mean to say that the flowers attain to that purity of colour that is apparent in the country, but they grow to a considerable size, are of good form and splendid substance. It must be a task of considerable magnitude to

FIG. 133.—PHAIUS BICOLOR.

keep the glass sufficiently clean for the admission of light, and the leaves free from the deleterious substances that float in the air of the modern Babylon.

Turning now to the individual plants, we may first glance at the Masdevallias, of which the collection of species is, as has been said, of exceptional excellence. One cool structure is given over entirely to them, while we find others requiring greater heat in a suitable house, with still more that may be described as of botanical interest in a third. From this some idea may be formed of the number of plants. We jotted down the names of a few of those in flower, and they comprised *Harryana armeniaca*, yellow and salmon; *Harryana lilacina*, *Harryana conchiflora*, cordata-Esradæ, *Stella*, *Gairiana*, yellow and purple; *Ellisiana*, and *Bella*, the latter being one of the plants secured when the Downside collection was broken up. In the warm house the six plants of *M. Lowi* were particularly noteworthy, as they have all been grown from a single plant having three leaves; one of them has now a dozen handsome leaves, which speaks volumes for the cultivation.

In a large span-roofed structure in two compartments we find *Cattleyas* in the first and *Aërides* and *Vandas* in the second. There are, too, a few *Lælio-Cattleyas*, such as *elegans* and *Pallas*, and *Lælias*, including the splendid *purpurata* *R. I. Measures*. The *Cattleyas* consist mainly of magnificent plants of *aurea*, *gigas*, and *labiata*, of which two of the best are *labiata alba* and *R. I. Measures*. The *Vandas* are of such uniform excellence and the collection is so comprehensive that one only will be specially named. That is *V. Parishii Marriottiana*, which is on a raft, and has seven beautiful growths. One does not require to see a plant like this in flower to admire it, as the splendid leaves are alone satisfying. In an adjacent house are the *Odontoglossums*. Owing to lack of space these have not been added to as have most others, and they are consequently almost all old plants or specimens that have been divided. We hear sometimes of *Odontoglossums* going back, but this is not borne out by the Cambridge Lodge plants. *Oncidiums* of the *macranthum* section are in luxuriant health, as are *O. papilio* and *O. Krameri* in another structure. Travelling a few more steps and we reach the *Cymbidiums*, including *Lowianum*, *eburneum*, *Traceyanum*, *giganteum*, and some hybrids. Hanging from the roof of this house, too, is a fine plant of the peculiar *Nanodes Medusæ*.

Cypripediums, individually and collectively, are superb in quality of flower and in the health of the stock. In and out of flower were observed *insignes Ernesti*, *Sanderæ*, and the *Harefield Hall* variety, *Lawrenceanum*, *L. Hycanum*, *callosum*, *Chajmani magnificum* (fig. 134), *venustum Measuresianum*, *Wottoni*, *Curtisi*, *C. viride*, *Rothschildianum*; hybrids of *bellatulum*, *niveum*, *leucochilum*, *Godefroyæ*, and many others showing the range of the collection. There are hundreds of seedling *Cypripediums* and *Cattleyas* for which it will be no easy matter to find space as they gain size and require larger pots. The collection of *Miltonia vexillaria* in variety is excellent; the plants are grown in one structure, and as the flowers expand they are transferred to what may be termed the show house. Here, in conjunction with *Lælio-Cattleya Schilleriana*, superb variety; *Cattleyas* *Wm. Murray*, *Mossia*, and *Arnoldiana*, *Lælia purpurata*, and others, they are making a brilliant display. The plants flower with the greatest freedom, and many of the blooms exceed 5 inches in depth and 3 inches in width. *M. Roezli* from its own particular spot is also employed for adding beauty and variety to the show house.

Time and space are, however, exhausted, and we must bring these notes to a close with a reference to the *Phalænopsis*. These have been reserved until the last because they perhaps show the most marked improvement of any one section. We can remember the plants when they only produced leaves of moderate size and substance, whereas now the foliage is of immense size and remarkable thickness; they are a picture of the rudest health, and are worth travelling far to see, even if not one single plant is in flower. We noted in bloom *Luddemanniana*, *tetrapsus* and *amabilis*. The *Dendrobiums* and others must remain unnoticed for the time, and in conclusion we may tender to Mr. Measures our congratulations on the extent and variety, as well as the excellent health, of one of the finest collections of Orchids that can be found in or out of London.

—ORACHE.

***Tropæolum speciosum*.**—It may interest your correspondent to know that after some trouble I am getting this plant to make a little growth in a corner between a north and a west wall, where, as far as I know, it gets no sun. I find that wire netting promotes the early growth better than twigs, I fancy because the metal condenses a certain amount of moisture. I have been long puzzled to know why this native of South America should only flourish in Scotland. As I understand you, it is drought, not heat, we have to guard against.—RET RAILL.

Feeding Roses.

RECENT copious rains have benefited Roses to a considerable extent, not only by washing and cleansing the foliage from dust, and assisting in freeing them of insects, but by moistening the soil. This renders the application of stimulants of greater benefit, as the special constituents of the manure applied are more readily held by the soil when the latter is moist and the roots have access to it as required, assimilating it into the root system and soon distributing it throughout the tree or bush. At the present time the demands of Roses are important. The large extent of foliage is constantly giving off watery vapour. In hot, dry seasons it is extremely trying for the Roses, especially if the soil should be poor and the roots are not able to abstract the food so much needed for the purpose of maintaining healthy growth. During the time, therefore, that moist weather prevails liquid manure may be applied, provided the soil is duly moist below. Farmyard liquid manure contains all the elements needed by plants, and generous doses given at brief intervals will greatly improve the vigour of weakly trees or bushes, promote the fuller development of buds in ordinary healthy bushes, and assist the superfluous energy to expend itself in the production of stout growths for the succeeding year. Much depends upon the vigour and health of bush, standard, and climbing Roses during the period of full growth, and every endeavour should be made to maintain a steady and continuous improvement throughout that period. In helping a Rose to develop its flower buds in the best possible manner it is obvious that benefit accrues in other ways. For instance, regular moisture promotes a satisfactory growth. The foliage plumps up and does better work which, reacting upon the roots, induces that desirable vigour indicating health.

Wall Roses often deteriorate, not so much from lack of good soil as from insufficient moisture in it, whereby the plant food may become available. Considering the importance of moisture at the roots as one of the chief means by which plants feed, it will be seen that feeding does not always consist of applying liquid manure or solutions of special chemical manures; but that before using these aids, going probably to expense and trouble in securing a supply, a copious application of clear water may prove the better treatment. It at least prepares the way for richer and more stimulating diet, but of itself it is food, and has the power to render soluble important elements locked up in the soil. Use plenty of water, therefore, in the first instance, or wherever it is found that roots are ramifying in dry soil. Roses on walls are especially liable to suffer from poverty of moisture. This can invariably be detected by the character of the growth, which will be weak and short rather than vigorous and long. This applies to strong-growing varieties, not to the naturally small and weak growers. Healthy growth, however, always asserts itself. On indifferent growth insects readily find a footing, and spread with remarkable rapidity. They should be destroyed or displaced by copious syringing.

A mulching over the roots after the soil has been moistened has the effect of preventing the speedy escape of moisture from the surface, and if the mulching consist of manure of a rich juicy character some of the virtues contained in it must be washed to the roots by the watering and syringing carried on. The mulching will also hold the water until it has time to percolate into the soil. On bare hard ground water runs off quickly, and if not mulched it should be pricked up with a fork. Nothing can be better than the drainings from stables and farmyards for Roses, but in many cases it is not easily attainable, hence recourse must be had to some means of preparing a suitable liquid. A rich liquid may be formed with a peck of any animal manure, such as horse, cow, sheep, or fowl manure, placed in a bag and sunk in a tub holding 30 gallons of water. Let it soak for a few days, stirring frequently, and apply undiluted. A similar quantity of soot placed in a bag, and treated to the same quantity of water, stirring in a spadeful of lime, and allow the mixture to clear, forms an admirable stimulant, improving the tone of the foliage, and increasing the colour in the blooms. Of chemical manures, superphosphate may be applied, dissolving half an ounce in a gallon of water, and apply weekly to Roses outdoors during the summer. It may be varied with sulphate of ammonia or nitrate of soda, each half ounce to the gallon of water, but use them separately. The advertised artificial manures are good, and may be used in solution at the rate of 1 ounce to 2 gallons of water, applying weekly. Sulphate of ammonia and nitrate of soda ought not to be used too frequently. Their action is very stimulating.—ROSARIAN.

Propagating Roses by Cuttings.

THE propagation of the tenderer and choicer varieties of Tea and Noisette Roses by cuttings is an admirable way of increasing stock. Small side growths having well formed leaves and partly ripened wood form good cuttings. They should be taken off the plant with a heel of the old wood attached. Growth that have flowered make suitable cuttings, as the wood is usually in the right condition, being neither too sappy nor too hard. The cuttings may be 3 or 4 inches in length, and should have at least two leaves above the soil when the cutting is inserted. In the first instance the cutting will have three leaves, but the bottom one must be removed and insert to the next leaf, that is, place the cutting to such a depth that the leaf will rest upon the soil. Four or 5-inch pots are a suitable size for the cuttings, which are best placed round the edge, four to six cuttings in a pot.

Drain the pots efficiently with a few crocks and some turfy pieces over them to maintain the drainage free and carry away superfluous water: equal parts of loam, leaf soil, and sand should form the compost. Place this material firmly in the pot, surfacing with sand and dibble in the cuttings, taking care that the base of each reaches the bottom of the hole. After inserting, give a good watering and place the pots on a moist base in a greenhouse, covering with a bell-glass, or in a box or frame which can be kept closely covered with glass until roots form. Shade will be essential to prevent the leaves flagging, also frequently sprinkle in order to maintain them fresh. Dispel damp by giving air occasionally, and wiping the inside of the glass.

Where a little gentle bottom heat is available cuttings of Roses will root sooner, though it is a good plan to place them first in a cool place, so that the base of the cuttings develops a callus, then with the stimulation of bottom heat roots will quickly be formed; but they must of course be kept close and shaded. Single joints of well ripened young wood may be propagated readily by this means. The gentle, regular heat and moisture of a Cucumber or Melon frame is most suitable. When roots form pot the plants singly, and return to the frame until established, after which gradually harden and grow in a cool greenhouse. The hardier varieties of Roses are easily propagated by cuttings of ripe growth inserted on a sheltered north border or in a frame in autumn.—H. T.

Small Fruits on Espaliers.

WHEN one considers how little room Gooseberries, Currants, and other small fruits occupy on espaliers, and what excellent fruit is produced, one begins to wonder why Apples and Pears are so almost universally grown thereon to the exclusion of the more suitable fruits named; for there can be no question that to select proper varieties of Apples at least, to plant and tend them, and keep them in thorough health and bearing on espaliers, is more difficult than most gardeners care to own.

The man who contentedly pinches his shoots in summer, snips them back in autumn, and is satisfied as long as the trees are young and vigorous, thinks it is very easy, and if he fails to get fruit on some of the finest Apples in existence when treated this way he calmly blames the season and thinks no more about it. But let any thinking gardener watch trees of, say, Cox's Orange Pippin when they are growing, and again when they have nearly filled their allotted space,

let him note the younger portions of the tree with its fine spurs and fruit, and contrast it with those parts that have been closely pruned for a year or two, and it will probably lower espaliers in his estimation, especially if the trees have been treated on the orthodox rule-of-thumb principle.

Now it is a matter of no small moment to have to root up as unprofitable trees that if judiciously treated would be just at their prime, and while I would not go so far as to condemn espaliers for these fruits entirely, I am sure we have far too many of them. There is not one variety out of three that is really suitable for growing as restricted trees, and a year or two of neglect even of these will cause them to fall into such disorder that many years of careful treatment are necessary to restore them.

Had these been trained on a fair system a little neglect would not so much matter though no system will stand it for long. I would like then to recommend anyone who wishes to make the utmost use of their resources to plant fewer Apples and more Gooseberries and Currants in any position where espaliers are necessary or can be used. A Gooseberry espalier tree on each side of a walk some 40 yards long has been planted about four years, and I have never had

cause to regret planting it. The amount of fruit that can be gathered is out of all comparison with that of bush trees when the quantity of ground is considered.

The quality of the fruit too is always the best of its kind, the finely flavoured choice dessert varieties coming to a size and development quite unattainable on bush trees. The roots are easily got at for all purposes of culture, and the fruit has the benefit of air and light to the fullest extent. As an instance of improvement in flavour I would mention that fine variety Telegraph. On bush trees as a rule it is not of the best quality for eating, but well ripened on trellises it is above the average and good enough to go anywhere.

Gooseberries on espaliers have the distinct advantage over wall trees that they are no more trouble to keep free of insect pests than when on bushes, rather the reverse, while on walls they are frequently eaten up with red spider, especially should the position be a warm one. Late fruit of such varieties as Warrington may be readily protected from birds, and the fruit at all stages is easily gathered. Thinning for preserving is therefore an easy matter.

Turning to Currants much the same benefits accrue, very fine and splendidly finished fruit following well considered culture. In this connection it may be well to note that when the fruit is expected to hang late in the season it is not advisable to pinch the breastwood too closely. I am referring more particularly to red varieties. The additional leafage is an advantage, as it serves to keep the fruit a little cooler under a hot July sun, and by ripening slowly, it develops fine colour, size, and flavour.

FIG. 134.—CYPRIPEDIUM CHAPMANI MAGNIFICUM.

Espaliers for Currants and Gooseberries may be taken to any reasonable height, according to individual circumstances, from 4 feet to 5 feet being a useful height for ordinary purposes. For anything above 4 feet I prefer an upright method of training, a shoot being taken along the lowest wire horizontally, and others run up from it at intervals of 9 inches. Thus trees planted at 6 feet 9 inches apart will have four upright branches on each side of the central shoot, and this is enough if the trellis is to be covered in a reasonable time.

Overcropping while the trees are filling up should be avoided, as it is apt to weaken the growth; but if properly fed from the surface by means of top-dressing with farmyard manure, very fine fruit may be taken during the first few years. As to the trees to plant, those in the second year from the cutting are best, and if ordering from a nurseryman it is well to say for what purpose they are required. Three shoots only are needed; the centre one should be shortened to a foot or less, the side ones an inch or two beyond the place where the first upright shoot is to be taken, provided of course the trees are strong enough to allow of this.

If weak cut back all three of the shoots to a few eyes, as it is only waste of time to leave in wood that is undeveloped, and consequently will not break strongly. In the formation of the branches "make haste slowly" is an excellent maxim. Pinch the upright shoots at every wire, and the horizontal branches at every foot. This will prevent having to cut away useless wood at pruning time, and insure a well-balanced flow of sap. It is well, too, to pinch the former a day or two in advance of the latter.

I am not an advocate for very close pruning in the case of these espaliers, for as mentioned the extra foliage is an advantage; but, then on the other hand, if the trees are allowed to get too thick the whole advantage of the system is lost, as this latter consists in a great measure in the freedom with which air and light play about the growth and fruit. A very light and cheap trellis will suffice for the purpose. In my own case I have six wires at intervals of 9 inches, with light iron standards at about 10 feet apart, also a straining post at each end. I have not the exact cost by me now, but I know it was not much more than 1s. per yard run for material, and any handy labourer can fix it. The whole should be painted a couple of coats, and if the wires are tightened occasionally by means of the ratchet arrangement on the straining posts, the fence will last for an indefinite time.—
H. R. RICHARDS.

FIG. 135.—STRAWBERRY TRAFALGAR.

Strawberry Trafalgar.

THOUGH many new Strawberries have come to the front during the past decade, none has caught the popular fancy to such an exceptional degree as Royal Sovereign. A few years after its introduction and while the stock was yet comparatively expensive, it was being grown on every hand, until at the present moment it would probably be a difficult task to find a garden without Royal Sovereign, or a market grower who did not consider it one of the best varieties in cultivation for early use. On its introduction the late Mr. Laxton considered it the best early variety he had raised, and such it has undoubtedly proved itself to be. Now Messrs. Laxton Bros. bring forward Trafalgar and say that "it promises to make a useful market as well as table fruit, as it is equally as good at the end of the season as Royal Sovereign is at the beginning."

At the Drill Hall on Tuesday, June 5th, when Strawberry Trafalgar was exhibited by the Bedford firm, it was recommended for an award of merit by the Fruit and Vegetable Committee of the Royal Horticultural Society, and the illustration (fig. 135) represents a typical fruit. The variety resulted from a cross between Latest of All and Frogmore Late Pine, and the habit—robust yet compact—is intermediate between the two parents. The plant is a free producer of

large to very large pointedly conical bright scarlet fruits. The flesh is white, firm, and richly flavoured. The leaves are often five-lobed, and are smooth and leathery, with a downy footstalk. The plants staged on the occasion named carried a heavy crop in various stages of development, but the flavour though, as has been said rich, was not so luscious as it will be when the plants are grown under the more natural conditions that suit the late fruiting Strawberries so well.

The Gardener's Assistant.

THIS, the first volume of a series, professes to be in some sense a continuation of "Thompson's Gardener's Assistant," of which three editions have already appeared, in 1859, 1878, and 1884 respectively. While, however, acknowledging its indebtedness to Mr. Robert Thompson of Chiswick, and the late Mr. Thomas Moore of the Chelsea Botanic Garden, for the basis of the idea (viz., a comprehensive treatment of practical horticulture for professional gardeners), it is so far as this present volume goes almost an entirely new work. On comparing it with the older editions the fact becomes at once apparent, and upon turning to the preface it is admitted by the writer himself.

But while every change in modern literature and journalism cannot be regarded as making necessarily for good, there is no denying that in this case the presiding genius of the undertaking has in every respect advanced upon his models; and this is noticeable not merely in latter-day points connected with science, such as cross fertilisation and hybridisation (in which a new school of specialists is arising), or in the matter of recently introduced novelties, or even in respect of *Orchidomania*, of which there is a premonition promising greater glories to come. To speak exactly, except in the department of tools and instruments, very little of the original work remains. Neither in style, treatment, nor arrangement are the old models preserved or imitated, and the result is that we meet with an improvement on every side.

Clearly the English scientific mind is emerging from the dry-as-dust stage and condescending to simplicity. It may be a sign of degeneracy in us that we cannot emulate the feats of our grandfathers, who devoured the leading articles of "The Times," drank port wine *ad libitum*, and perused patiently the black-letter law books or the philosophical reflections of Sir Thomas Browne. In matters intellectual, as in matters mechanical, the earlier tendency is towards overloading and complexity, the later towards neatness and lucidity. And this applies not only to ideas, but also to language, so that while the amount of our store of knowledge has increased the length of our sentences has declined.

Of these tendencies the present volume is a striking example. If it has not exactly constructed a royal road to the goal at which its readers aim, it has at least so macadamised and rolled the path that the readers will not be unnecessarily impeded upon their journey. Whether it be the question of the calendarial operations, or of descriptive and physiological botany, or of the fascinating subject of hybridisation, or of garden entomology (which is delightfully treated), or of "garden friends," or of the chemistry of garden soils, and of manures, one is impressed with the ease, the clearness, the compactness, and the general "modernity" of the treatment and the information. Moreover, it is no small recommendation that the authorities for much of the knowledge embodied in its pages are still alive, and have had a direct or indirect influence upon its production. It is beautifully illustrated (often in colour), and is in every way more in the nature of a work for perusal than for reference. Amid the torrent of imported works we have here an ample vindication of the practical and yet flexible character of the national intellect, of which we may be proud.

The Cider Making Industry.—We are informed that an International Congress respecting the cider industry is to be held in Paris from October 11th to 13th. The organising committee appeal to pomologists, growers, and authorities of all countries to give the conference the benefit of their knowledge and experience as regards the following questions, which are proposed for discussion:—1, Raising and planting Apples and Pears for cider and perry. 2, Principles on which to form a selection of the best varieties of fruits for wine or cider. 3, Experimental orchards and stations. 4, The teaching of fruit growing. 5, Drying and preserving wine fruits. 6, Use of yeasts in cider making. 7, Extraction, filtration, sterilisation of must. 8, The spirit present in cider and perry. 9, The cider and cider Apple trade in France and elsewhere. All communications in connection with the conference should be addressed to Mons. Jourdain, 21, Rue Mayet, Paris.

* "The Gardener's Assistant." A new edition by William Watson, assistant curator, Royal Gardens, Kew. The Gresham Publishing Co., 25, Farringdon Avenue, London, E.C.

The Kew Rockery.

THERE is probably no outdoor section of the great national garden at Kew that is such a perennial source of interest as the charming rock garden. No matter when a visit is made thereto many plants will be found in flower, and some of them will have such beauty as to warrant their purchase for the home rockery. If, however, the inspection is made in a time of plenty, the treasures will be so numerous and so varied as to preclude the possibility of the inclusion of them all in a limited space. The varied interest that attaches to the Kew rockery makes one wonder why more rock gardens are not found on all the estates of the affluent. It must be understood that by rock gardens is here meant a portion of ground set apart with stones properly arranged, so that the plants placed in the chosen positions will luxuriate, and not, as is too often seen, eke out a living death. There is a vast difference between a rockery or a rock garden constructed on rational lines, and with due consideration of the habits and require-

ments of the plants in flower than during the spring and early summer months, and at the present moment it is singularly rich in its diversified charms. Plants of all sizes producing flowers of all forms and colours are to be seen literally by the thousand, and the visitor cannot go 3 feet without seeing a dozen plants of the choicest type of beauty. First one pauses to admire the stately spikes of *Eremurus himalaicus* towering on the summit of the bank, and then stoops to examine the flowers of some miniature gem whose height may not exceed a couple of inches. A flowering shrub that demands attention is *Rubus deliciosus*, whose green leaves and chastely beautiful white flowers make a most attractive picture. When it is seen in such excellent condition as this, one wonders why it is so seldom grown in gardens; it is certainly equally as worthy of inclusion as many that now have a place. The bright yellow of the Spanish Broom shows up well from the grey background of the stones and the green of the neighbouring plants; while *Cytisus purpureus*, if less showy, is very beautiful and meets with many admirers. Standing up prettily on a easy ledge can be seen *Galax aphylla* (*Blanfordia cordata*), the heart-

FIG. 136.—THE ROCKERY AT KEW.

ments of the future occupants, and one in which the stones and rocks are thrown up irrespective of the wants of the plants that are expected to adorn them.

It will be conceded by every reader of the *Journal of Horticulture* who has had practical experience in the matter that there is no phase of gardening that is more difficult to manage than the formation of rockery. So many details have to be considered which involve many hours of careful study, that gardeners are, as a rule, only too pleased to hand the task over to a specialist. This is undoubtedly the best thing to do, but it is, unfortunately, not always feasible or desirable. Where such is the case intending rockwork builders will do well to journey to Kew and study closely the lines that were there adopted, and which have proved so signally successful. If they do this, and take copious notes, they will find the task they have set themselves much easier, while the results they will attain to will be far more satisfactory.

There is probably no better period to visit the Kew rockery to

make notes of the plants in flower than during the spring and early summer months, and at the present moment it is singularly rich in its diversified charms. Plants of all sizes producing flowers of all forms and colours are to be seen literally by the thousand, and the visitor cannot go 3 feet without seeing a dozen plants of the choicest type of beauty.

In a delightfully cool-looking corner, and springing from what at first glance is apparently the facing of stone, is *Rhombola pyramica*, the flowers of which always remind the writer of those of *Saintpaulia ionantha*; this looks particularly attractive, as also does *R. p. alba*. The flowers of the latter are precisely similar to those of the type, except that they are white in colour. When the two varieties are seen side by side, as at Kew, their beauties can be fully appreciated. In those positions suited to their requirements *Ribes* are comparatively numerous, but the only one noted in flower was *R. Douglasianum*, a dwarf-growing plant, that can scarcely lay claim to universal cultivation. Near by some magnificent plants of *Cypripedium spectabile* promise to produce an abundance of flowers in due course, as in fact do other hardy *Oreobala*.

Truly regal are the great clumps of *Osmunda regalis*, which even

at this early period of the year have fronds upwards of 4 feet in height. A rockery without Saxifragas would scarcely be worthy of the name, and at Kew there are many in full flower. Some produce minute blooms that almost require a magnifying glass to show their charms; while others have bold leaves and strikingly handsome flowers, whose effectiveness can be appreciated as well from a distance as at close quarters. Then, too, there are Geraniums, Dianthi, Lychnis, Phloxes, and a host of others that cannot be named at the present moment; a few have been chosen, and they must suffice for the time, and others will be enumerated as the season advances.

The Rhododendron dell is now just passing its moment of greatest beauty. The plants, large and small, have flowered magnificently, and the cool walks have proved a constant source of attraction to visitors. The hardy Azaleas have been superb, and the large plants have been literally smothered with blooms. An immense bed of Lilacs has taught many a useful lesson as to the seasons of flowering, while the various Laburnums have proved to demonstration that all the varieties at Kew are not good. In one place we see a tree bathed in golden chains, and in another a specimen that over its whole extent of branches had not more than a dozen puny racemes. But we will return to Kew again.—F. W. H.

Tuberous-rooted Begonias.

TUBEROUS rooted Begonias have, during the past few years, been making steady progress in the flower garden, and they are admitted by all who have attempted their culture in open beds during the summer and autumn months to be unique. It is a step, too, I feel sure, in the right direction, as by its adoption we see less of the vivid glare which has too often occupied the greater part of many summer beds. The formality of the design, too, is somewhat avoided, for happily we cannot pinch and pick, in other words mutilate the Begonia so as to form it into any set design, so that it must be allowed to grow naturally to see it in perfection. When thus seen they may be said to constitute one of the most enjoyable floral arrangements which any garden can contain. The Begonia delights in a free, light, sandy, and fertile loam, and commences flowering almost from the first joint, continuing successively to produce its many coloured blossoms till checked by autumn frost. Those who desire an attractive bed should never select the huge-flowered varieties, which are better for pots in the conservatory, or for exhibition.

The simplest means of obtaining a stock of Begonias is from seeds, which is easily managed provided the following rules be adhered to. Firstly, the soil, when the seed is sown, should be sufficiently dry to pass through a sieve of three-eighths of an inch mesh without clogging, then three parts fill thoroughly drained pots, making the surface even and very firm, sprinkle a little white sand on this to mark where the seed falls, and thus avoid sowing too thickly, in which case many decay. Secondly, after sowing the seed scatter very lightly from a wire gauze sieve (or if this be not at hand the fine rose of a watering can I have found an excellent substitute) a little dry silver sand, so as to barely cover the seeds, after which plunge the pots or pans in slight bottom heat, say about 60°, and cover with a piece of glass. If the soil is in the right state they will not require watering for three or four days, keeping the pots at this stage quite dark, as by so doing watering is dispensed with, for after all the watering pot is the greatest enemy in the raising of Begonias from seed.

The seed should be barely covered; in fact some growers do not cover it at all. I have frequently adopted the same practice with equal success; but knowing the great losses attending the injudicious use of the watering pot, I nearly always cover it as above described, and thus avoid the seed being displaced when vegetating, which is sure to end fatally. Watering, I may observe, should never be done till the seedlings have their second leaf. What appears to suit the seed best, and which falls very lightly on them, is the spray from the syringe given at a distance, and settling on the seed pots much as a thick misty rain. Thirdly, when the seedlings are up always avoid incessant sprinklings over the foliage. This is highly detrimental and often fatal to them, consequent upon their extremely succulent nature at this time. When they have reached the second and third leaf a lighter position near the glass will suit them, where they will soon make headway and be ready for planting, having been thoroughly hardened previously, and of course pricked off into boxes or pans in the usual way of small seedlings.

The other means of increasing this section of Begonias to which I shall refer is by cuttings. It is by this means that the best forms of singles and all the doubles are propagated, and which can only be performed where good tubers exist, capable of throwing up several strong growths. In adopting this method, and to avoid overcrowding and the consequent damping off, the cuttings should be inserted singly in small thumb pots, using rough fibrous leaf soil and plenty of sharp grit, passing all through a half-inch sieve, well rubbing the fibre through. The soil ready, the next thing is the cuttings, and this is

how I get them:—Taking half a dozen 3-inch pots and as many labels, I select the strongest and forwardest plants, having cuttings 3 or 4 inches long; these I detach with a sharp knife close to the tuber, securing where possible a slice of bark and a heel as well to the cutting.

Such cuttings as these are almost sure to form roots readily with judicious management. Those, however, that cannot be obtained in this way should be taken off as close to the tuber as possible, and where the naturally succulent growth is somewhat firmer. These latter, though by no means difficult to root, require the greater care. Having filled half a dozen pots, take them to the potting shed, potting them singly and labelling each one, defining the singles from doubles by placing the first letter of each word on the label as the case may require. When all are complete, plunge them into bottom heat of 60° or 65°, but on no account water them for the first two or three days.

It is the orthodox practice to water cuttings newly inserted at once, and, generally speaking, with softwooded plants it is the right way to prevent flagging. The Begonia, however, is extremely succulent, the stems being capable of sustaining themselves for days, even in a cutting state, without water, and sometimes longer, provided they are plunged in damp cocoa-nut fibre refuse and kept comparatively close. By the third or fourth day the cuttings will have begun to heal; in other words, be in the first stage of forming a callus. When this stage is passed the danger is considerably lessened, and presuming the soil is dry on account of the heat in the propagating house, a good watering may be given, leaving the lights off for three or four hours till the foliage is quite dry.

This watering under the circumstances I have described should last them five or six days, according to the weather at the time, after which all that are dry are best taken out singly and watered, for it is not an easy matter to direct a volume of water to any particular pot in the propagating case without wetting others. By taking them singly as described, each may be watered effectually without damping a leaf, a thing to be desired when propagating these Begonias from cuttings. After the tenth day air may be admitted by degrees, according to the progress of the cuttings, thus keeping them short and of sturdy growth, as, by being essentially greenhouse plants, they soon become drawn and weakly if kept too warm or too close. In three weeks or a month the majority will be well rooted, and having been exposed in the house for a few days may be placed in 4-inch pots. These will carry them through the first season, one of the chief points being to secure a sound tuber by the autumn.—F.

Notes on Figs.

EARLY forced trees require generous treatment after the first crops are gathered to enable them to swell the second crop. Syringe twice a day to keep red spider in check, employing an insecticide if necessary, but not such as will discolour the fruit, which is easily done by any corrosive substance, and frequently by rubbing with the hand. Afford liquid manure when watering is necessary, trees in pots requiring it daily, sometimes twice a day; and trees in borders once or twice a week, according to the extent of the rooting area. The second crop should be thinned before the fruit is the size of Walnuts, and in thinning reserve the largest at the base of the shoots. Trees in pots require top-dressing with rich material, malt culms added to loam being excellent, supplying a little fertiliser occasionally. Planted-out trees should be mulched with short, sweet, lumpy, partially decayed manure about an inch thick, renewing from time to time, so as to maintain that thickness.

When the fruit on trees in succession houses commences to ripen a free circulation of air must be afforded, and it should be warm, as cold air-moisture settles on the fruit and may cause decay or result in "spot." Attend to tying-in and regulating the shoots by thinning and stopping, so as to afford the fruit the benefit of all the light practicable. The moisture in the atmosphere will need to be moderated, not wetting the fruit, though if red spider attacks the trees the fruit should be gathered rather closely and a good syringing given, which will not injure the remaining fruit provided it is done early on a fine day, so that the moisture does not remain long on them. Do not allow any lack of moisture at the roots, yet guard against excessive watering, affording lessened supplies of water than when the fruits are swelling.

Trees for next year's early forcing in pots must not be neglected in any cultural essential or disappointment will be the consequence. They must have all the light possible, and be kept as near the glass as practicable, without touching, so as to secure sturdy well-ripened growth, keeping them clean by syringing and the application of an insecticide if necessary, and affording liquid manure to effect a stout growth. Suckers must be removed, keeping every plant to a single stem. When the growth is completed the trees may be stood outdoors in a sunny spot to induce rest, but the wood must be well ripened previously, and the sooner the better for early forcing. If any fruit shows it should be removed. This will not prejudice but favour the formation of bud Figs in embryo for producing the first and most valuable crop another season.—GROWER.

NOTES & NOTICES

Recent Weather in London.—Both Saturday and Sunday were brilliantly fine, and though gardeners would appreciate some steady, warm rains, farmers round London hope for continuous warm weather, as such will favour the newly mown hay. On Monday the heat was intense, the maximum shade temperature reaching 88°. On Tuesday morning there was a heavy rainstorm with some thunder, but it continued very close afterwards. In the evening there was a slight return of thunder with rain; Wednesday opened cooler.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, June 19th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Aquatic Plants," by Prof. G. S. Boulger, will be given at three o'clock.

Fruit Growing in England.—In spite of the increased facilities enjoyed by the foreigner in the shipment of fresh fruits to the markets of the United Kingdom every year, it is satisfactory to see that the English fruit grower more than holds his own against all comers. From the Government returns, it appears that the acreage devoted to fruit in Great Britain now exceeds 229,000 acres, and the extension bids fair to assume large proportions in the near future. Kent and Worcester at present take the lead as regards recent developments in this home industry. The output of Cherries, Apples, and Strawberries, particularly from Kent, is now enormous. The great increase in Worcester relates to Plums, Strawberries, and Gooseberries.

Crystal Palace Fruit Show.—The schedule of this the principal exhibition of British grown fruit, held annually in the United Kingdom, is before us, and remains substantially the same as in former years. The dates chosen are September 27th, 28th, and 29th, and it is hoped that the show will prove as signal a success in all respects as its predecessors have done. There are classes for practically all kinds of fruits that can be produced in the British Islands at that period of the year, and as in former schedules the small grower has abundance of opportunity to annex prizes in some of the smaller classes. There are sections in which of course only the large grower can show, but this does not necessarily exclude others entirely. Entries close on Thursday, September 27th, and intending exhibitors may secure schedules and other necessary information from the Secretary Royal Horticultural Society, 117, Victoria Street, London, S.W.

The Death of the Earl of Radnor.—By the death of the Earl of Radnor, which occurred on the 3rd inst., horticulture generally, and in the south-west in particular, has lost one of its staunchest supporters and most noble patrons. His lordship and the Countess of Radnor were ever ready to promote and help forward in every possible way any scheme for the advancement of horticulture, especially so amongst the cottagers and poor in their immediate neighbourhood. The beautiful demesne at Longford Castle affords abundant evidence of their devoted love of horticulture, and of the exquisite taste displayed in effecting the numerous improvements made there recently. The deepest sympathy is felt by everyone connected with horticulture towards the bereaved countess and the family in their sudden and severe affliction, intensified, as it now is, by the serious illness of the present earl, who so nobly left his home at the call of duty to fight for the empire.—T. C.

Mr. Peter Barr in New Zealand.—Some New Zealand papers to hand show that in April of the present year Mr. Barr, after his peregrinations in China and Japan, was enjoying himself among his kith and kin in the far away antipodes. He appears to have been lionised by the municipal authorities of Christchurch and Dunedin, and largely engaged in teaching them how to improve their public parks by way of making them more beautiful and enjoyable, after the manner, in some respects, of the parks of London. He seems to have been shocked by the prevalence of Lombardy Poplars, for he says:—"All over the place you have abominable Poplar trees, and they should be ruthlessly slaughtered. On the other hand you have the beautiful Weeping Willow, which is in itself a charm. Alongside a river it is the loveliest tree in creation. I refer to the Babylonia. It makes a beautiful landscape. These Weeping Willows are one of the great beauties of Christchurch."

Horticultural Club.—The usual monthly dinner and conversation of this Society will take place on Tuesday, June 19th at 6 P.M. The subject which has been put down for discussion is the "Clematis," and it will be opened by a paper of Mr. A. G. Jackman.

Inner Temple Gardens.—We learn that by permission of the Benchers the Inner Temple gardens were opened on Monday last, and will be open each week-day during the summer months from 6 P.M. till dusk, for the benefit of the children in the district. This is a privilege that will be immensely appreciated.

Ash and Box from Albania.—It is stated that these trees are now being raised in a regular manner in Albanian nurseries. Until recent years these have been used solely as fuel, and never exported as building wood, for which purposes Ash timber especially has considerable value for use in the interior of buildings. Boxwood, of large size, for the use of the engraver, is always a marketable commodity in Europe, and a new source of supply will be heartily welcomed.

Rhododendron Sunday.—Last Sunday is known as "Rhododendron Sunday," and the public were admitted to view the wonderful collection of these beautiful plants in Earl Darnley's Park at Cobham, near Rochester. Cobham is within an easy walk of Rochester and Gravesend, and both park and village are ideals for the artist, the admirer of the picturesque, and the thousands of lovers of the creations of the late Charles Dickens. The "Old Leather Bottel" has become a veritable Mecca for our cousins from the other side of the Atlantic, and its visitors' book contains a wonderful collection of distinguished names.

Bournemouth Pleasure Grounds.—Mr. Robert B. C. Scarlett, owner of the Shelley estate and the cliff frontage to the east of Boscombe Pier, on Wednesday, presented to the Mayor of Bournemouth for the town in perpetuity new pleasure grounds on the cliff front. The gift was originally made by the late Lady Shelley, but since her death Mr. Scarlett, her successor, has added to it by spending £1600 in laying out the site, and the Bournemouth Corporation spent a similar sum in providing shelters and seats, and other conveniences for the public. The grounds cover nearly 4 acres, and command magnificent views of Bournemouth Bay, the English Channel, the Isle of Wight, and the Purbeck Hills.

Amateur Rose Culture.—In the last issue of the "Rosarian's Year Book," Mr. R. E. West, the well-known and successful Reigate amateur, contributed an admirable article under the above title. This has now been issued in pamphlet form by the Surrey Seed Co., Ltd., Redhill, and having in view the fact that the whole of the information has been previously published, we are forced to the conclusion that the price, 1s., is too high. Had the pamphlet been offered at 6d. there can be no doubt that it would have had a vastly increased sale. Needless to say the information is most reliable, as it is the result of many years' practical experience in the production of the Queen of Flowers, both for exhibition and home adornment.

Gardening Appointments.—Mr. Robert Anderson, for the past fourteen years head gardener and manager on the estate of Capt. the Hon. A. E. Harris-Temple, Waterston, Athlone, and previously foreman in the gardens of his Grace the Duke of Buccleuch at Dalkeith Palace, and the Right Hon. the Earl of Rosebery at Mentmore, has been selected from upwards of 200 candidates to fill the responsible position of bailiff of Phoenix Park, Dublin, in succession to Mr. Wm. Dick, who retires after twenty-three years' service. Mr. James Tivendale, lately head gardener to Colonel Cosby, D.L., Stradbally Hall, Queen's Co., succeeds Mr. Anderson as head gardener to Capt. the Hon. A. E. Harris-Temple, Waterston, Athlone.

The Late Mr. R. D. Blackmore's Pear Garden.—The fame of this fruit garden, near Teddington Station, failed to secure purchasers when offered in moderate sized lots for building purposes last week by those able auctioneers, Messrs. Chancellor & Sons. Only a few low bids were made, but not a single lot changed hands. That may seem remarkable, considering that the ground is so admirably situated, being near the railway, and very close to Bushey and Hampton Court Parks, and the River Thames, and only about twelve miles from London. But the sale seems to have been hedged by conditions of so restrictive a kind that no one would make adequate offers. Most of the land has been planted a few years with Pear trees, and of the very best varieties, the trees being almost, if not wholly, of the pyramidal form. The plots had the advantage also of facing several well-made established roads.

Gifts to Gardening Charities.—We understand that the Welshpool Horticultural Society has been dissolved, and the surplus funds, some £200, divided amongst various charities. Through the kindly exertions of Mr. John Lambert, The Gardens, Powis Castle, the Gardeners' Royal Benevolent Institution has benefited by the distribution to the amount of £20, and the Royal Gardeners' Orphan Fund £10.

Royal Meteorological Society.—At the ordinary meeting, to be held in the rooms of the society, 70, Victoria Street, Westminster, S.W., on Wednesday, the 20th inst., at 4.30 p.m., the following papers will be read:—"Rainfall in the West and East of England in Relation to Altitude above Sea Level," by William Marriott, F.R.Met.Soc.; "Description of Halliwell's Self-Recording Rain Gauge," by Joseph Baxendell, F.R.Met.Soc.

Lectures at Chiswick.—Professor George Henslow, M.A., V.M.H., has kindly consented to deliver a series of four lectures in June and July to the students at Chiswick, and to any of the Fellows who like to be present. The lectures will be given in the Great Vinery at 8 p.m. June 20th, "Protoplasm: What it is, and How it Maintains Plant Life"; June 27th, "Protoplasm, the Instrument of Evolution among Plants"; July 4th, "The Phenomena of Germination"; July 26th, "The Uses of Leaves."

Bradford Horticultural Show.—The sixth annual exhibition of the Bradford Horticultural Society was held in the Drill Hall, Otley Road. The value of the prizes was increased to £56, and the entries have increased to more than 300. The quality of the exhibits, too, has improved, and a prettier scene than that presented in the hall it would be difficult to imagine. The principal exhibitors were:—Mr. John Brooke, Park Nursery, Heaton; Mr. W. Moorby, head gardener to Mrs. Knowles, Moorhead, Shipley; Mr. D. Wilson, Glusburn; Mr. T. Bell, head gardener to J. H. Rand, Esq., Baildon; and Messrs. Henry Clark & Son, Rodley. These divided by far the greater portion of the prizes. The much-coveted silver cup, presented by the Mayor of Bradford (Mr. W. E. Aykroyd), for the best group of plants staged for effect, was won by Mr. J. Brooke with a beautiful collection, in which Coleus, Palms, and Mosses formed prominent features.

Liverpool National Amateur Gardeners' Association.—A highly successful meeting was held on Thursday last in the Common Hall, Hackins Hey, Liverpool, under the presidency of Mr. A. W. Ardran, who expressed a hope that it would be a record year. Mrs. MacGregor took the prize for a lady's spray, and exhibited some fine Pelargoniums. Mr. Hoskyn, besides showing Pelargoniums, gained one of the president's prizes with a well flowered Petunia, and Messrs. Drake and Dodd took the other with some cut Cactus blooms. Mr. Robins won a prize for his Irises, and exhibited some magnificent Pansies, while Miss Francis won with three Viola sprays. The lecturer was Mr. R. Pinnington, of Roby, who gave short seasonable cultural notes on Gloxinias, Hydrangeas, Tea Roses, Oleanders (of which a very pretty spray was shown by Miss Hunter), Azaleas, and Zonal Pelargoniums for winter. A useful discussion ensued, in which Messrs. Muir, Tinsley, and Ardran took part, and a hearty vote of thanks was passed to Mr. Pinnington. It is hoped that the committee will arrange for a day's outing to Shrewsbury.

Bristol Gardeners' Association—The following papers will be read at meetings held at St. John's Parish Room, Redland, on the last Thursday in each month, at 7.30 p.m. June 28th, "The Culture of Strawberries in Pots," Mr. W. Staddon, Westbury-on-Trym. July 26th, "Sweet Peas," Mr. J. C. House, Coombe Nurseries. August 30th, "The Herbaceous Border," Mr. W. Ellis Groves, Redland. September 27th, "The Advantages to be Derived from the Study of Horticulture," Mr. J. H. Vallance, Redland. Prizes will be awarded on June 28th for a dish of Strawberries, not more than twenty-five; July 26th for six bunches of Sweet Peas, distinct varieties, six sprays in a bunch, shown with their foliage, and for six blooms of Carnations, distinct varieties, shown with their own foliage; August 30th for six single and six double blooms of tuberous Begonias, for six Peaches grown in the open air, and for six Nectarines grown in the open air; and on September 27th for two Ferns suitable for table decoration, in pots not more than 6 inches diameter. Certificates of merit will be awarded by the judges to exhibits considered sufficiently meritorious. Certificates of special merit will be awarded on the recommendation of the judges by the committee to exhibits of exceptional quality. The secretary of this flourishing society is Mr. W. Ellis Groves, Redland, Bristol, to whom all communications should be addressed.

Royal Botanic Society.—The first of the weekly promenades and evening fêtes at the Royal Botanic Gardens, Regent's Park, took place on Wednesday. The band of the 2nd Life Guards played in the grounds during the afternoon and evening, and a large number of Fellows and their friends enjoyed the beautiful grounds under most favourable conditions. At dusk the gardens were prettily illuminated. The fêtes will be continued every Wednesday, with the exception of June 20th, the day fixed for the special floral fête, until August 8th.

Heavy Thunderstorm.—A thunderstorm of exceptional severity passed over Northampton on Monday afternoon. Although lasting only twenty minutes it did extensive damage. Streets and houses were flooded, and hailstones as large as Walnuts broke hundreds of panes of glass. Conservatories, fruit trees, and flowers have suffered heavily.

Sussex Weather.—The total rainfall at Abbots Leigh, Hayward's Heath, for May was 0.68 inch, being 1 inch below the average. The heaviest fall was 0.22 inch on the 22nd. Rain fell on six days. The maximum temperature was 71° on the 6th and 28th, the minimum 35° on the 16th. Mean maximum 65°, mean minimum 42.07, mean temperature 53.53°—the average. Cold northerly winds have been much in evidence this month, but owing to the dry state of soil and atmosphere fruit bloom does not seem to have suffered much. If rain comes soon and warmer weather, there will be a good crop of all hardy fruits in this neighbourhood. We are ill-prepared to stand a dry June, the total rainfall for March, April and May being only 2.45 inches.—R. I.

May Weather at Belvoir Castle.—The wind was in a northerly direction sixteen days. The total rainfall was 1.86 inch; this fell on fourteen days, and is 0.50 inch below the average for the month; the greatest daily fall was 0.87 inch on the 8th. Barometer (corrected and reduced): highest reading 30.357 inches on the 29th at 9 p.m.; lowest reading 29.363 inches on the 3rd at 9 a.m. Thermometers: highest in the shade 66° on the 17th and 27th; lowest 27° on the 17th; mean of daily maxima 57.16°, mean of daily minima 40.96°; mean temperature of the month, 49.06°; lowest on the grass, 24° on the 17th; highest in the sun, 127° on the 27th; mean temperature of the earth at 3 feet, 48.83°. Total sunshine 151 hours 55 minutes, which is 35 hours 58 minutes below the average for the month. There were four sunless days.—W. H. DIVERS.

New York Weather and Roses.—We have been experiencing for a few days past the hottest weather on record for the month of May, the mercury having gone as high as 102°. The effect of this sudden jump to summer, on the cut flower product, can be imagined. The Roses, naturally, show the worst effects, and the quantity is such that even the prevailing job lot price of 2 dols. 50 cents a thousand is no temptation to the Grecian speculators. Everybody must make his bow to these indispensable gentlemen under present conditions, and nobody understands it better than the Greek himself. He is particular, says the "American Florist," as to quality at such times, and turns up his nose contemptuously at the lower grades of Roses. A little more of this torrid weather and there will be nothing to select from except lower grades, however.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

The weather has been bright and warm, the wind having changed from the north to a southerly direction during the latter part of the week. Showers fell on three days.

Carnation Mrs. A. Hemsley.

WITH reference to "W. S.'s" note, on page 463, the above Carnation was well known among growers a few years ago. It was raised at Mr. H. B. May's Dyson's Lane Nursery, Edmonton, about ten years back, when it was a great advance on any other crimson variety, and although further improvement has since been made the above is still grown to some extent. On June 21st, 1892, the Royal Horticultural Society's Floral Committee gave it an award of merit. Since the advent of Uriah Pike several other good crimson varieties have been raised from Winter Cheer crossed with the above varieties. Countess of Warwick I consider the best crimson with which I am at present acquainted. The flowers are well formed, with a good calyx, and of a bright claret crimson; it grows rather taller, but otherwise is of similar habit to Winter Cheer.—A. HEMSLEY.

Mr. Pearson's Election of Apples.

IN his remarks on this subject in your last issue Mr. A. H. Pearson mentions his regret that twenty-four out of sixty persons written to did not return him replies. I was one of the guilty parties, and rather glory in my reticence, seeing that Mr. Pearson so far forgot what was courteously due under the conditions of his application, to enclose a stamped envelope for the reply. The italics are mine, please note. Possibly he is a novice in Press matters, or otherwise he would have realised that the surest way to obtain replies is to enclose stamped envelopes with queries, even though he may not be asking questions that are of special interest to himself but are such to all fruit growers.

The Apple election provided by some thirty-one persons is not, I fear, of much value. To have a thoroughly representative election it should cover the whole kingdom, and be taken part in by at least 200 growers, each personally solicited—not by an individual, but by one of our influential gardening papers. My notion of an Apple election would be to first ask for lists of the best dozen of kitchen Apples and of dessert Apples for garden culture in bush or half-standard form. When the returns were in and tabulated, then the twenty of each section having most votes should be re-issued to the whole of the original constituency, and invite them to select from these scores the very best dozens. Then, when the results of this were tabulated, we should arrive at some definite conclusions as to which were the best Apples for the whole of the kingdom.—A. D.

MR. A. H. PEARSON has undoubtedly extracted some very serviceable Apples from his correspondents and published them on page 474 last week. That a condensation of varieties was needed many persons will freely admit, and also be obliged to Mr. Pearson for the start he has made. They will be also amused to find that there is one descendant extant of the old mystery men of the past who sold recipes for Auricula composts, killing lice, and making big Gooseberries. We must now look out for advertisements of his "valuable" selection of fortune-making Apples.

"Lectons is curus things, you never know what they won't do," observed a good and worthy worker in the fruit quarters after looking down Mr. Pearson's list. "What can you make of 'em," he went on to say, "when you find in the six standard Apples for cooking only two for summer sale, the rest late when the Americans are in?" On being told that there were three, he had the boldness to turn up his nose at Ecklinville because "it spotted so." He said, "The salesmen knew about it and put it out of their list, and besides they had four in, all earlies, that the growers left out of their six standards."

The critic was pointed to the list of "twelve bushes for cooking." "Well," he replied, he "didn't know they cooked bushes, but some of the sorts were good enough; it was a muddle all the same, as some grew three times the size of the rest, and a pretty show it would be if all were planted at the same distances; besides, there are too few earlies and too many lates in both cooking lists for money making."

Those are the views of a plain man who has had a good deal to do in his time both with raising and selling Apples. He admitted the late Apples near the top of the lists were as good as any, but was convinced they would not pay so soon or so well as the best of the earlies, as these had the markets to themselves "before the Yanks came in."

He did not think the table Apples far wrong, as all the lists nearly agreed, but would put Quarrenden before Blenheim as a standard for paying the sooner. On asking the man if he would make out better lists, he shook his head with the remark, "It all depends how you would plant, and how far apart for the trees for making the most

money off the land," and he muttered something as he went away about liking to know how Mr. Pearson would plant an acre if he had to buy other folks' trees.—A GLEANER.

Peaches for Market.

AS I have been growing Peaches and Nectarines for market for some time the article by "H. D.," on page 476, was of particular interest to me. That your correspondent is correct in his remarks anent the market I feel sure, as I have found no difficulty in disposing of my produce at remunerative prices. I am, as a matter of fact, so satisfied that the erection of a new range is in contemplation for the cultivation of Peaches and Nectarines, and I should be glad of the advice of "H. D." and other practical contributors on the following point:—I have a low wall about 100 feet long, against which I purpose placing a three-quarters span-roof structure divided into three compartments, or, perhaps, four; I thought of having a wooden front from the ground to the eaves, say 5 feet. Hitherto I have had to deal only with the regulation fan-shaped tree trained beneath the roof, but I am told that I shall find it more advantageous to adopt transverse trellises having the trees back to back. I learn that the system is practised and strongly advocated by Mr. Challis, of Wilton, and Mr. Summers, of Sandbeck. Now "H. D." does not refer to the method, but, perhaps, he will favour with his views on it, especially if he has had personal experience with it. I am much inclined to try the pot trees, and should be glad to know if they require annual repotting, and whether of Nectarines there is a variety superior to Early Rivers. If Messrs. Challis and Summers are readers of the Journal, perhaps they will say how many feet the transverse trellises are apart, and how far they extend into the house from the side?—LEARNER.

Potato Sets.

ON page 487 "Observer" makes an interesting reference to my notes on Potatoes, and the adoption of a course of planting small tubers for seed purposes. Deterioration from such a practice I had never anticipated, nor in the course of five or six years is there any signs of debility; indeed, my early Potatoes are this year as good as anyone could wish, and as vigorous as is desired. There is, too, a surprisingly good haulm growth from the small tubers planted this year, which promises to give as good returns, if not better, than in other seasons. Seeds obtained by this course is often a superior sample than would be had from a selection made from the everyday digging, and they have the advantage of remaining undisturbed until the whole is ripe. I should not have the least doubt about the result of a three or four years' test, suggested by "Observer," and I can unhesitatingly say that my stock of early Potatoes is better now than when they were first purchased, and in some varieties this extends to eight years. I know it is a favourite doctrine to decry small seed for ordinary planting, and for obtaining a normal yield this may be true, but for seed purposes such as I have adopted, I have not observed criticism, and I cannot recall an instance where the small tubers have been set apart specially for seed purposes, year after year. It is a mistake to allow such small tubers to remain unplanted until they are badly shrivelled. The earlier they are put in the better.—W. STRUGNELL.

The Oak and the Ash.

ONE of your correspondents in the *Journal of Horticulture* (page 483) says on the subject of the leafing of the Oak and the Ash, that "old traditions die hard." This is so, and I believe for the very good reason that they mostly contain a considerable amount of truth. Our ancestors were not such foolish persons as many people nowadays would seem to make them out to be. The rush of life being less, they observed Nature far more than their descendants do.

I have myself, in a general way, observed the relative times or dates of leafage of the Oak and the Ash for very many years, and have no hesitation in saying that they differ very considerably in certain seasons, and that, again speaking very broadly, the subsequent character of the weather bears a distinct relation to these differences. I cannot go so far back as C. W. Brown, in the "Daily Mail"—viz., to 1816, neither can I concur in his statement that the seasons after 1869 have been average ones. The year 1879 was probably the most disastrous wet season on record, and the "seventies" generally were wet. The year 1893 was a record dry year, and the last few years have, on the whole, been the same.

Now, in the "seventies," according to my observation, the Ash was regularly ahead of the Oak in leafing, and often by a very long way, but of late years the Oak has been as regularly ahead of the Ash. Of course, what is true of one part of the country need not be true of another, but I am speaking mainly of the southern half of the kingdom. I know that last year in the south the Oak was much before the Ash

in coming into leaf, and I also know that there the drought was abnormal. I also know that, leaving the neighbourhood of London on one day in August, with the grass so burnt up that a north country friend of mine inquired seriously how anything was ever kept alive in the south, I travelled to Northumberland, and there saw all the meadows with great round yellow patches on them where the grass has been temporarily destroyed owing to the hay "pikes" having been standing there so long on account of the wet. Whether there the Ash had preceded the Oak, or *vice versa*, I, unfortunately, did not ascertain.

No one, I suppose, believes that because one species of tree is in leaf earlier than another, therefore the season will be wet or dry, but I think it is not beyond the bound of possibility that the character of, say, a winter may bear some relation to the character of the subsequent summer, and that—especially in view of the fact that the Ash is a water seeking tree—the character of a winter may in some degree influence the time when different species of trees come into leafage.

"There are more things 'twixt heaven and earth
Than are dreamt of in our philosophy."

—A. H.

Bricks and Mortar or Land.

THERE are no doubt many persons who, having a certain amount of money to invest, ask themselves seriously whether speculation in bricks and mortar will be more profitable than land; they wish to do the very best they can for themselves, and generally, it must be added, choose the former. True, they may purchase land immediately contiguous to a fast-growing suburb of an important town, and either commence building themselves, or sell out as soon as possible at a good profit.

The condition of the Royal Horticultural Society is almost precisely that of the investor of capital—its council is between two stools, and it is greatly to be hoped will not bite the dust. If all the Fellows were of the same opinion as "An Old Fellow" (page 484) they would plump for a new Chiswick, and, to a certain extent, the air would be cleared. Such, however, is not the case, for amongst those scientists whom your correspondent goes out of his way to scorn are some men of keen business ability, and they favour bricks and mortar, not because as "An Old Fellow" suggests, they want to bring the society down from its present eminent position, but because they consider the horticultural hall in London would be more generally advantageous to horticulture and horticulturists throughout the kingdom. But as your correspondent has no reverence for the opinions of scientists, at any rate in this matter, I should like to remind him that there are many practical business men who favour the establishment of a hall. Of course it will be said that they do this because it will redound to their own benefit. Exactly, and the greater the number of them who can be induced to see the matter in this light the better, as they will then give more than moral support to the scheme.

In either case—whether we have a new garden or a new hall—I should like to ask where the money is coming from to make the purchase? The society has comparatively little money or assets, so, perhaps, the members of the council will make themselves responsible individually and collectively for any money that has to be raised? Or if, as has been suggested, the Fellows are to be approached with a view to securing their monetary assistance, I think they should have a further opportunity of expressing their opinions on the subject before the council commits the society to any definite scheme. As it is absolutely impossible to bring the whole body of the Fellows together at one vast general meeting, they must perforce be approached in some other way.

I do not know the precise number of Fellows, but I think it would be quite feasible for each one, in the British Isles at least, to be sent a reply postcard containing certain definite questions. For example, there might be the following:—

Are you in favour of new garden?

What will you subscribe towards its establishment?

Are you in favour of a new hall?

What will you subscribe towards its erection?

Each Fellow on receipt of this would draw his pen through the scheme he opposed, and write "yes" to the first question of the other, and the amount he would give to the second. This may be looked upon as proxy voting, but it is not really so; it is simply a whip-up from the council to the Fellows for financial assistance to one of two objects. The cost of the reply cards would not be great, and the labour involved would be more than repaid in the prompt settlement as to which alternative would be most acceptable to the general body of Fellows.

I am not one with "An Old Fellow" when he asserts the hall would only be occupied once a fortnight, and for the remainder of the year be useless. If we have a hall it must be erected with a view to securing the support of other arts and sciences; but these are matters that cannot be discussed at the moment. I am, however, convinced that with due consideration from an architectural aspect a building could be erected that would not cost much more for maintenance than the estimated annual outlay of £3000 on Limpsfield, if that site be chosen for the new Chiswick.—AUDI ALTERAM PARTEM.

Notes on Eremuri.

THE magnificent collection of these stately plants at the Drill Hall on Tuesday, 5th inst., must be my excuse for sending these notes. It is not suggested that they contain any particularly fresh information, but the culture of *Eremurus* may not be familiar to all the readers of the *Journal of Horticulture*, and the suggestions may therefore prove useful. Another reason for their production at this moment of high pressure in the flower garden lies in the hope that from their perusal other growers may be induced to cultivate a few, so that they may not suffer in the future from the unwarrantable neglect that has been their lot in the past. It cannot be claimed for *Eremuri*, as it can for some of our numerous border plants, that they will adapt themselves to every position. Their habit of growth is such that to put them in certain situations would not only mar the beauty of the *Eremuri*, but would also detract from the charm of the surrounding plants. For the back of a wide border, however, the upper terrace of a rockery, or even in the centre of a large bed, they are admirable, and might with general advantage be more largely employed.

I am unfortunately not able to speak authoritatively of the whole of the species, as I have only had practical experience with *E. robustus* and *E. himalaicus* (fig. 137); and superb as is the former, I think, all things considered, the latter is the better of the two. Whether it is the soil or the situation that does not suit the former I am unable to determine, but marked success has not attended my efforts with it so far. *E. himalaicus* has, however, done splendidly with me, and is now flowering magnificently. It produces its stately spikes each year, and with the exception of the very cold winter of 1894-5 it has not suffered materially. From what I saw of *E. Elwesianus* at the Drill Hall, I assume it is a variety of *E. robustus*; in any case it is exceptionally handsome. I have read in the *Journal* of one or two others that are worth growing, but unfortunately I have not a complete set, so that reference is impossible at this moment. It may have been in the same article, too, that, if my memory serves me rightly, there was a reference to the plants dying after having produced a spike, but I have not been troubled in this respect up to the present.

When we first procured a couple of plants, one each of those previously indicated, they were inserted on a warm border in the ordinary soil, which is very shallow. Though the specimens were fine ones they made practically no progress; in fact it may be said that they were unsatisfactory, but the reason was not apparent. Thinking carefully over the habits of the plants, and bearing in mind the thick fleshy roots they produced, the trouble was eventually ascribed to the poverty of the soil. Fortunately this was a condition of affairs that was easily remedied. We took out the mould to a depth of upwards of 2 feet and over a considerable area. In place of the old we put excellent loam, with the lower layer of which was mixed some decayed manure, and with the upper layer a little flaky leaf mould and very coarse sand; of course the passing away of water was insured before the good compost was put in. The result of this simple expedient has been most gratifying, especially, as has been said, with *E. himalaicus*, as the plants have never given us a moment's anxiety since.

At the outset elaborate preparations were made to guard against frost, as it was understood the plants were susceptible of injury at the tips during the late winter and early spring; but it was labour wasted. With the exception of a flower pot we now use no form of covering material, though what would be the result in the event of a severe winter I am not prepared to say. We have found a much more serious enemy than frost, and that is the slug. These pests are always voracious, but they appear particularly so when they reach the young growths of the *Eremuri*, for they will absolutely spoil them unless promptly checked, which my fellow gardeners will agree is by no means an easy matter. However, patient night work with a lantern during the critical period does wonders, and it is rare that any material damage is done. If they are left to their sweet will the plants are quickly ruined, a fact of which a friend has had conclusive proof.

I am looking forward to the time when specimens will be found in many gardens. Generally speaking the plants are comparatively new, and as consequence have been almost prohibitive in price, but now that larger stocks are being worked up it is hoped that the reduced cost will be the signal for very greatly increased cultivation. They are worthy of every care, and in comparison with some plants that could be named they present scarcely any difficulties to the enthusiastic cultivator.—W. R.

Fig. 137.—EREMURUS HIMALAICUS.

The Royal Horticultural Society.

Scientific Committee, June 5th.

Present: Dr. M. T. Masters (in the chair); Mr. Veitch, Rev. W. Wilks, and Rev. G. Henslow, Hon. Sec.

Tulipa Gesneriana diseased.—Some roots received from Mr. Mann, Penhill Close, Cardiff, were forwarded to Dr. Smith for examination and report.

Iris with diseased roots.—Mr. Wilks brought some plants showing premature decay in the foliage. He observed that he had received reports from all parts of England of a similar condition among *Irises* of all sorts. The roots appeared to rot close to the rhizome. They were also sent to Dr. Smith.

Odontoglossum synanthic.—A flower from a spray on a plant of *O. triumphans* (?), sent by Mr. Pitt, illustrated the twin condition of two coherent flowers; the columns, however, were free from each other above the combined ovaries, as well as the two labellums.

Fendlera rupicola.—Mr. Gumbleton exhibited a flowering branch of this unique tree, there being but one species to the genus. It is a native of Texas and New Mexico, and a near ally of *Philadelphus* or *Syringa*, as popularly known; but while the ovary is inferior in the latter genus, it is superior in *Fendlera*.

The Climate of Johannesburg.

THE whole of the Free State, and the southern half of the Transvaal, consist of wide, treeless, rolling grass plains. Across them ox-waggons travel like ships on the open sea; the railway stretches like a brown thread; and even an army in close formation, seen from a kopje at the distance of a few miles, looks little more than a snake winding its way through the veld. Bloemfontein and Kimberley stand at an altitude of about 4000 feet in the midst of the great plateau. North of these towns the country almost imperceptibly rises until the Witwatersrand is reached. To the north of this the Crocodile runs swiftly down through valleys rich with a tropical luxuriance of growth and deadly in the summer months with malarial fever. Through the Witwatersrand from east to west for twenty-five miles the main gold reef lies, and in the centre of the Rand stands Johannesburg, at an altitude of 5600 feet above the sea, and more than 1000 feet above the summit of Table Mountain. The climate which this position gives is ideal. It is the hill climate of the tropics, than which the world contains nothing more delightful. The buoyancy of a mountain atmosphere with but little of its rigour has an exhilarating effect, stimulating alike to health and energy, which no other part of South Africa enjoys to the same extent. The languor of the coast is almost unknown. The atmosphere is as transparent as the ultimate ether, and the brilliant sunlight of the day is only rivalled by the splendour of the night. When the moon is up, says a writer in the "Saturday Review," no other light is required and the Boer with his waggon travels more by night than by day. The starlight serves when the moon fails.

The rainfall is abundant, but comes down for the most part in heavy storms in the summer. It is usual during January and February, two of the hottest summer months, to have one or two series of some three days' heavy and continuous rain. But the rain once down the sun again reigns supreme. Preceding the thunder storms in summer, and sometimes for days together in the winter, dust, the one drawback to perennial magnificence of climate, becomes a trying feature in the health and happiness of life. Johannesburg has not the fog, slushy snows, and eternal rain of other lands. But it has its dust storm. Sometimes for minutes together the opposite side of the street is blotted from sight by a blinding wall of moving red sand. The unfortunate wayfarer with difficulty struggles along—now partially opening one eye, and now the other, he gropes his way; his mouth, eyes, ears, hair, clothes, filled with grinding particles of sand. When he gets home even his house affords but a partial shelter—the finer particles of a South Africa dust storm drift in every room and every cupboard. Dust is swallowed with the soup at dinner; it lies on the pillow at night; in the morning it floats a thin film on the water of the bath. But this is an occasional not a constant nuisance, and it is largely to be controlled by mending the roads. In fact dust is only to a very small extent to be regarded as a climatic defect. The winds, the tormenting half-gales of the High Veld, which are so common through the winter, in whatever other way they may try mankind only produce dust in any great quantity where roads or debris heaps occur. The veld itself, although only loosely knit together by a

tufted vegetation of rank grass is sufficiently compact to resist almost entirely the winds that sweep it. At times it is true even the veld has dust storms—what dry country has not in the presence of a gale?—but they are trifling compared to the dust storm of Johannesburg.

From nature then man has little to complain of. The climate of the high veld in the Transvaal on which Johannesburg is situated is almost perfect. It is man himself that is vile. Mortality in Johannesburg is high for two reasons. The one is abominable sanitation, the other an indifferent water supply. Typhoid is the Nemesis of these defects. Both are capable of remedy. Epidemics of typhoid occur periodically in the summer and autumn in Johannesburg and along the mines. These are preventable, but hitherto the inhabitants of Johannesburg have been denied all control of their own municipal affairs. Rich revenues contributed for municipal purposes by the Uitlanders have been principally used in other directions, and what little has gone to the town has been administered by a board, on which the controlling power was of the ignorant Boer order, assisted by incompetent Boer officials. The result has been a heavy annual death roll from preventable disease, in numbers almost as great as those produced by the war. Of the country around Johannesburg it may fairly be said that it enjoys Johannesburg's advantages of climate without its disadvantages of sanitation. The land is in many places not only capable of cultivation, but fertile and productive. Trees grow readily, and many plantations have sprung up both in the various suburban townships and in the surrounding country. To the north of Johannesburg the land falls away rapidly, but among the slopes and valleys of this district there are many fertile spots which would well repay cultivation.

Pretoria, which is in this more broken country, is 2000 feet lower than Johannesburg, and has a warmer and less bracing climate. North-west of the Rand is the quaint little town of Rustenburg. Here an almost tropical luxuriance of vegetation is found, and Bananas and Orange groves line the streets. The climate is warm and more tropical in character, but is nevertheless healthy. Malaria, which is scarcely known at Johannesburg, begins to be found in the low country north of Rustenburg and Pretoria, and in the valley of the Crocodile occurs at time severely. Yet in the winter this low district, the Bush Veld as the Boers call it, forms a delightful hunting ground. There the Boer with his waggon, his family, and his herds, often sojourns through the winter months, moving from time to time to find fresh pastures for his herds or seek fresh game for his rifle. There is one feature in the climate common both to Low Veld and High Veld which is distinctive and unique, unique alike in its grandeur of effect and in its danger. It is the South African thunderstorm. This is perhaps most terrible when it courses along the summit of a range of hills such as the Witwatersrand. During such a storm there are moments when the air is a blaze of fire. The rain falls in such a deluge that the surface of the ground is like a lake. Between the flash and the report there is scarcely an interval, and the peal of the thunder is almost one incessant roar.

A Text-Book of Botany.*

IN issuing this work, extending to some 600 pages, Messrs. Macmillan have had in view the needs of the advanced student. It cannot in any respect be considered as an elementary treatise, and a man must have made himself a good practical field botanist during the summer months in order to appreciate sitting down with his microscope for the other half of the year to a careful examination of specimens under the guidance of this volume. It deals with questions of structural and physiological botany in the first half, and does this in so thoroughly exhaustive a manner as to lead the casual reader to suspect immediately that so much of solidity can alone proceed from the Teutonic brain. This is correct, since no less than four professors in the University of Bonn have co-operated in its production. The second half of the book deals with the special botany of the Cryptogams and Phanerogams, and here again we find much more concentrated food for reflection admirably illustrated by diagrams. The last quarter consisting of a descriptive classification of the monocotyledonous and dicotyledonous plants is a résumé of the characteristics of all the leading orders as known in the larger works of Hooker and Lindley, also illustrated with beautiful diagrams, many of them in colour. As a handy digest of more comprehensive works it is in every respect to be recommended, and seeing that of its 600 pages only six lack an illustration of some sort, the earnest botanist will in perusing it find many subjects of pleasure as well as instruction.

* A Text-Book of Botany (Strasburger), translated from the German. Macmillan & Co. 18s.

The Pear Maggots.—These are a terrible scourge this season, worse than ever. They are just leaving the Pears now they have done the mischief. Is there any practical means of checking them on grass orchards?—J. HAM.

Soap Trees.—There are several trees and plants in the world whose berries, juice, or bark are as good to wash with as real soap. In the West Indian Islands and in South America, says a contemporary, grows a tree whose fruit makes an excellent lather, and is used for washing clothes. The bark of a tree which grows in Peru, and of another which grows in the Malay Islands, yields a fine soap. The common Soapwort, which is indigenous to England, is so full of saponine, that simply rubbing the leaves together in water produces a soapy lather.

A Pea and Bean Pest.—At the last council meeting of the Royal Agricultural Society of England the consulting entomologist reported that numerous complaints had recently reached him of injuries by the Pea and Bean weevil—an insect which notches the leaves and stems in a curious and characteristic manner. It is rather remarkable that the grub of this insect has only been noticed as the cause of injury to the Pea and Bean roots during the past two or three years, though the weevil itself has been a familiar pest for many years. It is stated that the best method of dealing with the weevil is to give a liberal application of soot when the crop is wet with a heavy dew.

Infection in Fruit.—Tasmania has taken alarm over the dangers of infection that lurk in colonial fruits that have passed through ports where the bubonic plague has made its appearance. Amongst others, the "Hobart Mercury" contends that there is often great carelessness in the way in which this kind of food stuff is stored and matured; and although people have themselves begun to be careful in their consumption of these articles (which is the best kind of caution), they call on the Government to appoint special inspectors. Indeed, all customs' offices at home and abroad ought to use special care in admitting consignments of produce from any infected source, as, after all, ships' rats are the most lively source of plague contagion.

Edible Peas.—How well these look this season! Although in many places they suffered from that too well remembered sharp April frost, which left its mark upon them, they seem to have grown out of it, and I do not think I have ever seen them looking better than now. At Feltham Messrs. Veitch & Sons have 18 acres of Peas, all looking wonderfully well. Great quantities of these, especially the stock trials, are staked, but such a season as is the present can only give a first-rate trial, and a look over these Peas in the open field at Feltham will presently prove to be very interesting. I noted several new ones and in bulk those with which the name of the firm has been thoroughly identified. There will also be a huge trial of Dwarf French Beans amongst many other plants.—WANDERER.

A City Rectory Garden.—It can scarcely be said that gardens are very numerous in the heart of the City of London, or that the conditions are particularly favourable to the production of plants and flowers of the finest quality. Strenuous efforts are, however, made to grow plants by the few, and amongst them must be included the Rev. Clementi Smith, of St. Andrew's-by-the-Wardrobe. Here in the small rectory garden, completely girdled by high buildings, Mr. and Mrs. Smith enter enthusiastically into horticulture. They have a few square yards of garden with a large greenhouse, and it is really a matter for surprise that such a diverse collection of plants can be grown in such a limited space. I had the pleasure of seeing it a few days ago, and am looking forward to a second visit, as it will be more than interesting to know what plants will succeed and what will fail. Of one thing everyone may be convinced, which is, that if personal care and coaxing can persuade a plant to grow it will receive both from Mr. and Mrs. Smith. The former is, as, perhaps, readers of the *Journal of Horticulture* are aware, somewhat of a pomologist, and has Apples in his fruit case that would not shame many a professional gardener with much superior fittings.—F. W. H.

Philadelphus Boule d'Argent.—Now that this most excellent variety is becoming more and more plentiful, I suppose we shall have the old varieties going out of cultivation. There can be no doubt that P. Boule d'Argent is particularly useful at this season of the year for the embellishment of the conservatory, especially when the plants are kept dwarf and are as profusely flowered as a number I saw at the Temple Show. I have only three plants, but I find it so valuable and so much admired that I must take the first seasonable opportunity of considerably increasing my stock. Few plants have been more appreciated by my employers, who, as a rule, are not keen on novelties, but would rather remain loyal to the old favourites that have been grown in their gardens and glass houses for about a quarter of a century.—R. J. P.

Ayrshire Potato Crop.—The protracted cold weather has apparently been responsible for considerable damage to the prospects of the early Potato crops on the Ayrshire seaboard. The sharp frosts about the middle of May nipped the shaws considerably, blight being reported in the Girvan Valley, where the earliest and best crops are usually grown. It is not expected, says a daily paper, that the injury will be permanent in so far as its effects on the yield are concerned, but as the primary object in these early districts is to be on the market before the general supplies arrive, the delay is serious from a financial point of view. Several of the most advanced and healthiest crops have already been sold at what are vaguely declared to be very high prices. Those who are fortunate enough to have good early crops will naturally reap a rich monetary harvest, but for the ordinary grower the season does not promise well.

Hybrid Streptocarpus.—I had the pleasure of seeing the huge collection of these singularly interesting and beautiful greenhouse plants Messrs. Jas. Veitch & Sons have at their new Feltham Nursery, and can well sustain what "F. W. H." has written about them. Remembering what Streptocarpaceae were not very many years ago, it is hardly possible to do other than marvel at the great advance made in them through intercrossing and selection. The colours and markings are becoming more varied each year, and whilst the plants are far more floriferous and robust the flowers also are showing finer form. It is impossible for anyone having florist's ideas in them not to find admiration for all those which not only have clear decisive markings or hues, but also have bold mouths and rounded edges to the lobes. In colouration many are so charming that they bid fair soon to rival the Gloxinia, if not in size at least in beauty.—OBSERVER.

Seedling Verbenas.—Whilst Mr. Gardiner may have good reason to lament the decadence of the Verbena in named form, as bedding or other decorative plants, yet there is much reason to be gratified over the evident resurrection of the flower in bedding arrangements in the seedling condition. So marked has been the advance made in seed stocks, that one often sees in beds of mixed seedlings flowers of such excellence that in the days of the old varieties to which Mr. Gardiner refers, and which I well remember, the best of the seedlings of to-day would have been regarded as grand additions. Seed of Verbena is relatively cheap, and easily raised if sown in shallow pans stood in a little warmth, furnishing strong plants to bed out at the end of May. Later in the summer a good mixed bed becomes a beautiful object. It is also so easy then to propagate by cuttings any that have specially fine qualities. We have in these seedlings a much greater range of colours than the old named varieties gave us.—A. D. K.

Weed Destruction.—An interesting experiment is at present being conducted at the trial grounds of the Royal Agricultural Society of England at Woburn. This experiment has been instituted with the object of testing to what extent the nature of the soil influences the presence of certain kinds of weeds, and also of discovering the most effective as well as the most economical methods of eradicating certain of the most troublesome of our common farm pests. The wild Marigold, wild Onion, wild Oats, and wild Poppy are receiving special attention in this respect, as also are Spurry and Sorrel. The soils in which these weeds naturally grow profusely are being submitted, says the "Farmer's Gazette," to chemical examination in order to ascertain if they contain any constituents likely to determine or influence the presence of these particular weeds. The application of lime is being tried for a destruction of wild Marigold, and an effort is being made to exterminate wild Onions by the use of carbolic acid. The outcome of these experiments will be eagerly looked for by agriculturists in all parts of the kingdom.

Mulching.

THE process of applying various substances as a covering for soil above the roots of trees and plants, to prevent evaporation, and so preserve uniform heat and moisture, is a natural one. In Nature the gradual change that overtakes everything has one primary object—*i.e.*, to make dust of all things. All over the surface of the land evidence exists of a natural mulching process—the ceaseless decay or reduction of parts called “weathering.” The effect of this, combined with the growth and decay of vegetation, is to promote the formation of soil and subsoil. Taking the surface of the earth, there exists a crust of vegetation. First we encounter a dark band of fine particles of earth crowded with rootlets and forming the true soil—the layer of most complete decay. Then on digging further we reach a broken-up layer, through which strong roots of the vegetation descend, and this is termed the subsoil. Excavating still lower rock is reached, which, shattered and torn or worn at the top, shows the earlier stages of disintegration. Worms, insects, and larger animals that die upon the surface add their mouldering remains to the uppermost deposit, and together with the decaying vegetation supply mineral as well as organic matter, on which the fertility of the soil so much depends. These also furnish the organic acids, which, absorbed by percolating rain water, help to decompose rocks.

The carpet of verdure, the fine mould, and the rougher material underneath, called respectively turf, soil, and subsoil, reduce weathering or decay, yet not wholly, for if the process ceased plants growing on the surface would dwindle and die. Impoverishment of the soil undoubtedly takes place by successive generations of the same plant, but the natural vegetation is for the most part mixed, and the process of weathering not entirely arrested, as successive generations of plants are able to draw nutriment from the soil. In Nature forests may decay and be replaced by shrub and grass, while vast tracts are practically barren through accumulations of peat precluding disintegration of the underlying strata. The causes, however, are mechanical, for draining transforms the moor as well as the morass from sterility to fertility. The downs bear their verdure undiminished because the weathering process continues, for though the grassy turf protects the surface, the underlying rock gradually decays supplying new food indefinitely.

Other agents besides quiet atmospheric disintegration and the accumulation of vegetable and animal *débris* mulch the surface of the earth with fine mould. The countless ground insects, and the still finer particles of mould swallowed and conveyed to the surface by the common earthworm, sometimes, according to Darwin, as much as 10 tons per annum over an acre of ground in some places, represent natural mulching, while the holes mean atmospheric air and rain water let into the soil for the oxidising and dissolving the rocks. All forms of mulching are conservative of the soil's moisture and protective of the soil's warmth. Wet land is proverbially cold, whether in a dark coat (peat) or a grey (chalk). Sand possesses a minimum of water-absorbing and retaining power, that of clay being five times, and humus or peat six times greater. It follows that fine sand will hold more water than coarse, and the finer the soil, therefore, the smaller the spaces between the particles the more water will be held, the drainage being efficient. It is also noteworthy, that if gravel allows water to percolate more freely through it than coarse sand, the underground water or soil moisture will rise considerably less in the gravel than in the coarse sand when the surface becomes dry. In passing to finely divided soils clay has the highest suction for soil moisture, but it bakes in droughty weather, cracks, and lets out the soil moisture into the air. Chalky land yields, perhaps, more underground water to the surface soil than any other, but the retention is not so great as that of the finer divided vegetable mould.

Now one of the chief objects of good cultivation is to cut off the supply of underground moisture so as to prevent its evaporation into the atmosphere. Nature assists this by surfacing the earth with fine mould, and by the *débris* of vegetation. The cultivator digs and trenches the ground, well knowing that the finer and deeper the soil the better will be the crops. Further, the surface is kept loose by hoeing, and thus lets in the air and rain, and also conserves the warmth and moisture of the soil, the fine tilth causing the rising moisture to spread through the soil beneath the surface instead of escaping into the air without passing through the plants. Thus the soil moisture and food elements are got into the crops and profit accordingly accrues.

A rough, cracked surface, on the other hand, allows the underground water to escape freely into the open air, and the crops are distressed for lack of moisture. In certain soil it is almost impossible to keep a loose surface, and it is not always feasible to procure material to prevent its running together with rain, and in dry periods being preserved in almost every direction. Still this is the best conservative of the soil moisture, and no pains should be spared on a stiff soil to secure and maintain a fine surface. The fact of the underlying stratum cracking is not then so material, as the surface soil will cut off the underground water, so that it will be at the service of the crop.

We thus arrive at two points in relation to the conservation of soil moisture. One, the fine soil resulting from atmospheric disintegration of rocks, which, as in cultivation, is in the condition best calculated to absorb the sun's heat, and allow the rain and atmospheric air to enter the ground. This corresponds to the good tilth of cultivation. It is, however, the nature of soils to become compact, which favours capillary attraction, so that a distinction must be made between natural and cultivated soils. In the former the surface working is effected by the action of burrowing animals, while in the latter the process of hoeing or other surface cultivation operates towards the same end. The other point is that of the dead natural vegetation acting as a mulch. The parts forming the *débris* are the remains of recent vegetation disposed all ways, but mostly parallel to the earth's surface, and they protect the soil from cold in winter and from heat in summer. Of course the recent vegetation passes by degrees into the state of complete decay, and in its various stages represents the organic matter of the soil called humus. It is known by its dark colour, and this means heat-absorbing power; while in the opposite direction it implies cold, for it absorbs water and keeps the soil damp. Of its other properties nothing need now be said, suffice that the points appertaining to mulching be clearly defined, namely, the use of littery material in winter as a protection against cold, and its employment in summer as a preservative from heat or drought.—G. ABBEY. (To be concluded.)

Carnations in Pots.

THE excellence of Carnations, either when grown as specimens for adorning the greenhouse or conservatory or for the production of blooms for cutting, is beyond question. They are never unsightly except when mismanaged. As cut flowers they are invaluable, and for massiveness of form and grateful perfume are unsurpassed. I have Carnations in flower more or less all the year round with very little trouble, and for the benefit of your readers whom it may interest I give an outline of the system which has been very successfully adopted for many years.

In September the desired number of cuttings are taken, choosing those that are vigorous; then the requisite number of 5-inch pots are prepared to receive them by being well drained. On the potsherds a layer of decomposed manure is placed, and then the pots are filled three parts full with a compost of loam and leaf soil and a dash of sand, the remaining space being filled with pure sand. The cuttings are inserted rather thickly, and having dipped the pots in a pail of water to insure saturation they are placed near the glass in the front of a cold pit, where they remain all the winter, and receive no more attention except a judicious watering occasionally. The following March the cuttings, being well rooted, are potted singly in 3-inch pots, and replaced in their old quarters; here they are kept moderately close for about a week, and receive no water except a sprinkling with the syringe two or three times a day. This renders shading unnecessary, and is, I think, preferable.

When rooting freely in the fresh soil the plants are watered thoroughly as they require it, and the leading shoots are pinched off in order that three or four side growths may start near the base of each of the plants. In about two months' time they will be ready to shift into 6 or 7-inch pots according to their size. At this and all successive pottings it is well to use the soil in a rough lumpy state. The loam we employ is rather light and poor when we get it, but is brought into splendid condition by being stacked one year prior to being used. Layers of turf and stable manure are built in alternately, with a sprinkling of bonemeal, and the whole is thoroughly soaked with liquid manure as the operation proceeds. After the 8-inch shift the plants are grown in a frame, with slates below the pots to prevent the ingress of worms, and watered freely, the growth being equalised by pinching. The sashes are taken off altogether on fine nights, so that the plants may be refreshed with dew.

In September, or as soon as the roots have thorough possession of the soil, the plants are shifted into 10 or 12-inch pots, and in these they commence to flower the following spring. When the plants become rootbound we supply them with weak liquid manure made of sheep droppings, a little guano, and soot. Under this treatment they continue to flower for months, producing that fine dark foliage which is so characteristic of healthful vigour. Those required for later flowering are pinched back, while if very large specimens are wanted they are potted in 18 or 20-inch pots. For large pots mix a quantity of broken crocks with the soil to keep it sweet, for if it becomes sour the plants sicken and die. Before shifting them, too, they are well watered, and do not require any more until they have rooted in the fresh soil; but flagging is prevented by the frequent use of the syringe. That system is, I consider, essential to the successful repotting of large plants. Now that the plants are large enough, it is

an easy matter to have a continuation of bloom. With good management they may be kept alive for many years, and by judicious pinching in spring and keeping a few plants in a growing temperature—45° to 50° all the winter—flowers may be had at any time.—M. C.

Perennial Asters.

To do justice to the perennial Asters and their usefulness as border flowers would require far more space than is available, yet no survey, however condensed, of hardy border flowers could be considered anything like complete which did not, at least, give a résumé of the genus and a

FIG. 138.—ASTER NOVÆ-ANGLIÆ PULCHELLUS.

brief mention of some of the most valuable species and varieties. As a dwarf plant for the front of the border we have the charming *A. alpinus* with its blue flowers, only raised above the soil from 6 to 10 inches. It is surpassed by the varieties *superbus* and *speciosus*, and those who wish a white flower of similar character will find it in the white variety. *A. alpinus* is easily grown, but it has the fault of being a favourite of the slugs, which are very destructive of it in autumn. *A. Amellus* is a fine plant of comparatively dwarf habit and with very large flowers. They are of a fine blue, but they are rather inferior to the varieties *bessarabicus* and *Riverslea*.

Aster cordifolius and its varieties are very pleasing on account of their graceful habit and the multitude of flowers they produce. *Cordifolius elegans*, *major*, and *Photograph* may all be named with confidence. *Acris*, with its variety *dracunculoides*, are of good bushy

habit, and give plenty of lilac-purple flowers. A charming flower is *Coombe Fishacre*, which has fine flesh coloured flowers, and is most pleasing when in full bloom. *Amethystinus* is a rather nice flower, though some of the newer varieties are superior. A favourite of the writer is *diffusus horizontalis*, which is a late bloomer, and gives a profusion of its red and white flowers, which are exceedingly small. The variety *pendulus*, which has white flowers, is also a desirable one. Then *ericoides* is, of course, indispensable with its elegant sprays of white flowers. Its variety *Clio* is lovely also; it has beautiful blush blooms. A neat dwarf plant is *dumosus*, which grows about 18 inches high, and has mauve flowers. *A. lævis* has fine long sprays of deep blue flowers, and its rather numerous varieties are well worthy of attention. *Ariadne* and *Calliope* may be mentioned as good varieties of this species.

A. grandiflorus is unfortunately too late in flowering for most gardens. This is to be regretted, as its flowers are so fine in size and in the violet-blue colour they give. *Lindleyanus* and its variety *nanus* are also good, the latter being a good plant for rock gardens. *A. lino-syris*, the old "Goldilocks," is the only yellow Starwort I know of. In addition to its colour, its Flax-like foliage is an attraction to many. In *Aster novae-angliae* and its varieties we have a most valuable set of plants, giving us not only some shades of purple, but also some of rose and crimson—both of much value in the season at which they bloom. *Roseus*, *ruber*, *Wm. Bowman*, *Woolston*, and *pulchellus* (fig. 138) would make a good selection.

In the varieties of *A. novi-belgii* we are embarrassed by the wealth of numbers. It is by no means easy to select from among them without omitting some of great beauty. They are constantly being added to, and some new varieties appear in trade lists every year. The old *Robert Parker*, about 5½ feet high, has not yet been superseded, although I believe that an improved variety will soon be in commerce. There is more than an ample choice among the remainder, which range in height from 18 inches to nearly 6 feet in ordinary soils. Of whites we have *Madonna*, *John Wood*, *Harpur Crewe* and others. I should take these three in the order named. Of various shades of mauve-pink, lilac, rose, and blue, one may name *Edith*, *Ella*, *F. W. Burbidge*, *Irene*, *Maia*, *E. G. Lowe*, *Margaret*, and *Top Sawyer*, with the earlier *lævigatus* and its variety *Madame Soymier*, the former of these two being a well known favourite for bedding when associated with early *Chrysanthemums*.

The few varieties of *paniculatus* give a boon for cutting in the shape of the fine sprays yielded by *W. J. Grant*, whose blush-white flowers are generally admired. *Puniceus pulcherrimus* is one of my favourites, with its red stems and blush flowers. *Versicolor* gives us blossoms which change from white to rose, the different colours on the plant at the same time attracting the attention of many persons.

Aster vimineus gives us lovely sprays of flowers; the type, *Cassiope* and *nanus* being all good. Their flowers are white. *Tradescanti* is also the delight of those who like elegant sprays of small white flowers and neat foliage. This brief commentary upon the Starworts or Michaelmas Daisies cannot be concluded without a reference to a Himalayan species named *Thomsoni*, which comes early into bloom and is very distinct from others. There are many others, of course, but the number is so great that all cannot be referred to now.

It seems almost needless to say anything about the cultivation of a plant so easily grown and which needs so little care. Yet it has some wants, and attention to these will result in a better display and in greater satisfaction being afforded to the grower. As a general rule the most of them are adapted to border cultivation. Some are, however, of rather aggressive habit, and, if allowed to do so, will soon take possession of the space which should fall to another plant as well as its own. Seedlings, too, ought not to be allowed to grow up along with the old plants, or they will injure the latter. They may be transplanted and put in some spare place, where they may be selected from when in bloom. There is still a vast possibility of improvement in the Starwort, and the seedling raiser will have at least the chance of finding a variety of much excellence. Where time and space can be spared a sowing of seeds from some of the best forms may well be made annually.

Some of the stronger growing Asters are of great worth in the wild garden, and many of the others make capital bedding plants, either alone or in association with other flowers. Generally speaking, all should have the best of soil, though I have seen in some gardens several of the taller Starworts so strongly grown that they were unwieldy and less beautiful than if restricted in their height. It may be mentioned that the taller Asters may be cut down when they have made some growth. This will render them rather dwarfer.

—S. ARNOTT.

Buddleia Colvilei.

WRITING of this plant Sir Joseph Hooker says:—"It is certainly the handsomest of all Himalayan shrubs, and it is impossible to exaggerate its beauty as seen in the borders of a Sikkim forest, covered with pendulous masses of rose-purple or crimson flowers relieved by the dark green leaves." In European gardens there has been little chance to see it at its best, as it proved a shy bloomer, but in the two or three places where it has flowered it has quite upheld its high reputation, for, in addition to being the most beautiful Buddleia in cultivation, its elegance and beauty give it a high place among flowering plants. In 1892 it first flowered in the British Isles in the garden of Mr. Gumbleton, Co. Cork. Several times since it has flowered in the same place, its flowering also being recorded from Shropshire and Southampton in recent years, while at Kew it is now flowering for the first time.

In habit it makes a large bush with long arching branches bearing large quantities of deep green leaves 6 or 8 in. long by 2½ wide. The flowers (fig. 139) are borne in drooping panicles 9 in. or a foot or more long from the extremities of the shoots. Individually they remind one of a small Pentstemon flower about 1 inch across the mouth. They vary greatly in colour on different plants, those of the Kew plant being a very deep red. Except in favoured localities it is not perfectly hardy, and even in those places it is better against a wall. Mr. Gumbleton grows his plant outside, and it is also growing out of doors in Shropshire, but at Kew it is planted in the Himalayan house, where it appears to be quite at home. It grows well in light loam, requires plenty of thinning, and full sun.—W. D.

Notes from Gunnersbury.

A Prolific Nectarine Tree.

FILLING the roof of one moderate sized house at Gunnersbury House gardens is a single tree of Lord Napier Nectarine. It has been planted some twenty-five years, and may be regarded as having carried full crops for at least twenty years. In all cases the fruits being pushed up on to the upper side of the tree, there seems from below to be a poor crop, but looked at from above the crop is seen to be a wonderful one, every fruit being visible. This year the tree carried 500 fruits, certainly a heavy crop, yet very fine and superbly coloured. Last year the crop was lighter, being only 300; still if for twenty years the average crops were 400, the tree would have in that time produced 8000 fruits, and have thus proved to be exceedingly profitable. Taken at the low price of 6d. each, the total value would have been £200, but it would, because the fruits were early and so very fine, have represented a much larger sum. There is no reason why the tree should not under Mr. J. Hudson's skilled attention continue to fruit for many years.

[This splendid tree was illustrated in the *Journal of Horticulture*, July 27th, 1899, page 81.]

Pot Gooseberries.

In a very large span house at Gunnersbury Park Mr. Reynolds has, with many of other fruits and flowers in pots, some fine circular shaped Gooseberry bushes in large pots. These are about 3 feet in height, and each one comprises some half dozen erect stems, forming cordons, kept hard spurred, and are carrying large crops of fruits. The products seem to be quite as satisfactory as is found in any form of fruit culture in pots. One or more of these plants are well worth illustrating. The varieties are of the best dessert, and the fruits produced come not only fine, but are clean and well matured. It is not difficult to keep such bushes clean, and though they need constant attention in the matter of watering, yet it is not greater than other pot trees require. Of course swelling fruits are now assisted with waterings of liquid manure.

A Tree Killed by an Iron Seat.

On the lawn at Gunnersbury House, Mr. Leopold Rothschild's residence, is the stem of an Ash tree now quite dead, but which presents the strange spectacle of having been killed by an iron trellis or rod seat, which many years ago was fixed round the stem at a short distance from the ground. In placing it no allowance seems to have been made for the tree trunk to swell, with the result that in time the bark overgrew and enclosed the inner circle of iron rod. This eventually checked the downward sap flow to such an extent that the alburnum grew over the ironwork of the seat so much that ere killing the tree the bark nearly covered the seat, and in two or three places did so absolutely, even running over and forming points as though molten metal had so far overrun the seat, then been suddenly hardened. It is so far an interesting object as showing how careful those persons should be who fix seats round tree stems.—A. D.

Horticultural Shows.

Tamworth Pansy and Viola Show.

June 4th.

THIS exhibition was held in the grounds of Tamworth's historic Castle, the gate money to be given in aid of the "Castle Purchase Fund." Entering the show tent the visitor's attention was arrested by a brave array of Pansies and Violas. Mr. W. Sydenham and family were responsible for the decorative floral designs, chiefly à la Viola in composition, and some estimate may be formed of the display in question when it is stated that about 100 feet of staging was laid under contribution, and incontestably proved the adaptability of the soft-toned colouration of the Viola and its shape for such decorative effects. In the competitive classes Miss Sydenham and Miss M. Sydenham were respectively awarded the first and second prizes for floral designs in Violas, whilst Miss Stuchfield was also deservedly awarded a first prize for a floral harp of Sweet Peas and W. Allen Richardson Roses.

In the open to all class for forty-eight Fancy Pansies the competition was confined to Mr. John Smellie, Busby, Glasgow, the first prize-winner; and Mr. T. Naden, Derby, the well-known cottage exhibitor, both having fine blooms of the leading varieties. The same exhibitors secured the prizes in the classes for twelve Fancy Pansies and twelve seedling Fancy Pansies, whilst Mr. Naden was accorded the premier award for twenty-four Fancies, dissimilar; and Mr. W. B. Fowler the second prize, both having fine representative collections. The class for twenty-four sprays of Violas was interesting, the first prize being awarded to Mr. John Smellie for a meritorious exhibit. The second prize was given to Mr. Councillor Waters for a good exhibit. For twelve sprays of rayless Violas the order of merit was reversed.

Prizes were offered for amateurs residing south of the Humber. The first prize for twenty-four Fancy Pansies was secured by Mr. T. Naden for very fine blooms of some of the leading varieties; Mr. W. B. Fowler followed. For twelve the same competitors secured the awards. For six Messrs. T. Naden, Paul, and Fowler were the respective winners. For six Fancy Pansies, one variety, Mr. Naden took the first prize with a new seedling named Mrs. T. W. Sanders; and Mr. Baldwin second with David Rennie. For six seedling Pansies, in three or more varieties, Messrs. T. Naden and Fowler occupied the positions as named. For twelve sprays of Violas, distinct, Mr. Councillor Waters was the only exhibitor, and was accorded the first prize. For six the same exhibitor gained the first, and Miss Hanmer the second prizes. Classes open to amateurs residing within twelve miles of Tamworth Town Hall.—For twelve Fancy Pansies, dissimilar, Mr. J. W. Paul and Mr. Fowler were the respective winners. For six the order was repeated; and for three blooms, one variety, Mr. Fowler was the only exhibitor.

In the miscellaneous exhibits Mrs. W. Sydenham was awarded a special prize for a basket of mixed Roses. A gold medal was deservedly awarded to the same exhibitor for the grand display already mentioned, and in which, it should have been remarked, a nice collection of hardy flowers was included. He also exhibited a special board of Violas containing several new varieties, amongst which the best were The Sultan, an extraordinary variety of a shaded dark brown colour, and resembling a butterfly both in shape and colour; Sydenham's Scarlet Viola, apparently a cross between a Fancy Pansy and a Viola, and may prove the forerunner of a new class; and Mrs. W. Sydenham, a rayless rich yellow coloured Viola of first-rate substance and form, also habit and constitution, which is considered by Mr. Sydenham as the best he ever raised.

Royal National Tulip Society.

Northern Exhibition.—June 2nd.

THE annual exhibition was held in the Free Library, Middleton, near Manchester, on Saturday, June 2nd. Considering the miserable nature of the weather experienced during the last month, the quality of the flowers, especially those exhibited by Messrs. Noedham and Bentley, left little to be desired; but from one cause or another few exhibitors put in an appearance, and a sad feeling prevailed as one remembered the great fights for the cup in the days of Dr. Hardy, Dr. Horner, Samuel Barlow, R. Headly, David Barber, Wm. Kitohen, Wm. Whittaker, Daniel Woolley, Wm. Parkinson, John Hepworth Wm. Lea, and others—now gone to their long home. And if exhibitors were few, visitors were scarce also, although crowds of people passed the door on pleasure bent. In these rapid days the quiet beauties and refinements of the Tulip appeal to only a few people in the North of England, and unless a great change occurs the Northern Exhibition will be numbered with the things of the past. The bright spot of the day's proceedings was the visit of the veteran grower and raiser, Mr. James Thurstan, of Cannock, who brought with him a collection of his own seedlings, which were much admired. Some of the bybloemens would undoubtedly displace Talisman and Adonis were they in general

cultivation. Tryphena and Mrs. Thurstan are gems in the rose section, and the bizzarres, which had evidently Paxton and Hardy blood in them, would be of value. Beyond Mr. Thurstan's seedlings novelties were scarce—in fact, the surprises of the show were the feathered Magnum Bonum, Vicar of Radford, and Talisman, exhibited by Mr. Needham, which have not been seen in such good style for thirty years at least. There was an excellent competition between Messrs. Needham and Bentley for the cup, which was this year given by Miss Willmott, of Great Warley; but the super-excellence of the former's feathered flowers decided the matter in his favour. Following is a complete list of the awards made by the judges, Messrs. Simonite, Sheffield; Barratt and Housley, Stockport; and Whittaker, Royton.

Class 1. *Twelve rectified Tulips, two feathered and two flamed in each class.*—First, Mr. O. W. Needham, Hale, Cheshire, with Talisman and Chancellor, flamed; Trip to Stockport and Talisman, feathered

roses. Fifth, Mr. John H. Wood, Middleton, with Duchess of Sutherland and Talisman, flamed; Bessie and Violet Aimable, feathered byblœmens; Sir Joseph Paxton and Sulphur, flamed; Sir Joseph Paxton and William Wilson, feathered bizzarres; Aglaia and Modesty, flamed; Modesty and Annie McGregor, feathered roses.

Class 2. *Six rectified Tulips, one feathered and one flamed in each class.*—First, Mr. Needham with Talisman, feathered and flamed byblœmens; Sir Joseph Paxton, feathered and flamed bizzarres; Mabel, flamed, and Heroine, feathered roses. Second, Mr. Bentley, with Bessie, feathered, and Josephus, flamed byblœmens; Samuel Barlow, feathered and flamed bizzarres; Count de Vergennes, feathered, and Annie McGregor, flamed roses. Third, Mr. Mellor, with Bertha, feathered, and Talisman, flamed byblœmens; Lord Frederick Cavendish and Sir Joseph Paxton, flamed bizzarres; Mrs. Collier, feathered, and Mabel, flamed roses. Fourth, Mr. Moorhouse, with Bertha, feathered and

FIG. 139.—BUDDLEIA COLVILEI.

byblœmens; Sir Joseph Paxton and Dr. Hardy, flamed; Sir Joseph Paxton and Magnum Bonum, feathered bizzarres; Mabel and Annie McGregor, flamed; Mrs. Atkin and Vicar of Radford, feathered roses. Second, Mr. J. W. Bentley, Stakehill, near Manchester, with Thurstan's 213 and Beauty of Litchurch, flamed; Bessie and Queen of the May, feathered byblœmens; Sir Joseph Paxton and Samuel Barlow, flamed; Samuel Barlow and Masterpiece, feathered bizzarres; Aglaia and Mabel, flamed; Modesty and Comte de Vergennes, feathered. Third, Mr. Alfred Moorhouse, Wakefield, with Talisman and Queen of the May, flamed; Trip to Stockport and Bertha, feathered byblœmens; Sir Joseph Paxton and Samuel Barlow, flamed; Masterpiece and Sir Joseph Paxton, feathered bizzarres; Aglaia and Annie McGregor, flamed; Modesty and Mrs. Lea, feathered roses. Fourth, Mr. Wm. Mellor, Wakefield, with Adonis and Bessie, flamed; John Henry and Trip to Stockport, feathered byblœmens; Dr. Hardy and Sir Joseph Paxton, flamed; Sulphur and Lord F. Cavendish, feathered bizzarres; Annie McGregor and Mabel, flamed; Mabel and Sarah Headly, feathered

flamed byblœmens; Masterpiece, feathered, and Sir Joseph Paxton, flamed bizzarres; Modesty, feathered, and Annie McGregor, flamed roses. Fifth, Mr. Wood, with Alice Gray, feathered, and Duchess of Sutherland, flamed byblœmens; William Lea, feathered and flamed bizzarres; Modesty, feathered, and Aglaia, flamed roses.

Class 3. *Six rectified Tulips, one of each class, for small growers only.*—First, Mr. George Eyre, Ripley, Derby, with Adonis, feathered, and Talisman, flamed byblœmens; Albert, feathered, and Masterpiece, flamed bizzarres; Modesty, feathered, and Annie McGregor, flamed roses.

Class 4. *Three feathered Tulips, one in each class.*—First, Mr. Bentley with Adonis, Rifleman, and Mrs. Atkin. Second, Mr. Needham with Talisman, William Annibal, and Sarah Headly. Third, Mr. Moorhouse with Talisman, R. Yates, and Mrs. Lea. Fourth, Mr. Mellor with Violet Aimable, Lord F. Cavendish, and Mrs. Collier. Fifth, Mr. Eyre with Bessie, Masterpiece, and Comte de Vergennes. Sixth, Mr. Wood with Violet Aimable, Sir Joseph Paxton, and Modesty.

Class 5. *Three flamed Tulips, one in each class.*—First, Mr. Needham with Talisman, Sir Joseph Paxton, and Mabel. Second, Mr. Bentley with Talisman, Samuel Barlow, and Tryphena. Third, Mr. Moorhouse with Queen of the May, Sir Joseph Paxton, and Annie McGregor. Fourth, Mr. Eyre with King of the Universe, San José, and Aglaia. Fifth, Mr. Mellor with Mrs. Jackson, Sir Joseph Paxton, and Mrs. Collier. Sixth, Mr. Wood with Alice Grey, Masterpiece, and Aglaia.

Class 6. *Two Tulips, one feathered and one flamed, maiden growers only.*—No exhibit.

Class 7. *Two Tulips, one feathered and one flamed.*—First (Samuel Barlow Memorial prize), Mr. Bentley with Cyril, flamed, and Elizabeth Pegg, feathered. Second, Mr. Needham with Sir Joseph Paxton, flamed, and Trip to Stockport, feathered. Third, Mr. Moorhouse with Aglaia, flamed, and William Annibal, feathered. Fourth, Mr. Eyre with Mabel, flamed, and Trip to Stockport, feathered. Fifth, Mr. Mellor with Lord Denman, flamed, and Lord F. Cavendish, feathered. Sixth, Mr. Wood with Sir Joseph Paxton, flamed, and Modesty, feathered.

Class 8. *Single Blooms.*—

Feathered Bizarres.

- 1 Mr. Needham with Masterpiece
- 2 Mr. Needham with Attraction
- 3 Mr. Bentley with Sulphur
- 4 Mr. Moorhouse with Masterpiece
- 5 Mr. Needham with R. Yates
- 6 Mr. Needham with Lord F. Cavendish
- 7 Mr. Needham with Samuel Barlow
- 8 Mr. Needham with Sir Joseph Paxton
- 9 Mr. Bentley with Albert
- 10 Mr. Bentley with Duke of Devonshire

Feathered Roses.

- 1 Mr. Needham with Modesty
- 2 Mr. Needham with Modesty
- 3 Mr. Needham with Jane
- 4 Mr. Bentley with Mrs. Atkin
- 5 Mr. Bentley with Annie McGregor
- 6 Mr. Needham with Sarah Headly
- 7 Mr. Bentley with Mrs. Collier
- 8 Mr. Bentley with Heroine
- 9 Mr. Moorhouse with Rose Hill
- 10 Mr. Eyre with Miss Nightingale

Feathered Byblæmens.

- 1 Mr. Bentley with Elizabeth Pegg
- 2 Mr. Bentley with Talisman
- 3 Mr. Bentley with Adonis
- 4 Mr. Needham with Elizabeth Pegg
- 5 Mr. Bentley with Mrs. Jackson
- 6 Mr. Bentley with Fanny
- 7 Mr. Bentley with Beauty of Litchurch
- 8 Mr. Bentley with Nellie Hughes
- 9 Mr. Moorhouse with Violet Aimable
- 10 Mr. Moorhouse with Bessie

Class 9. *The best feathered Tulip.*—Mr. Needham with Magnum Bonum. *The best flamed Tulip.*—Mr. Needham with Mabel.

Class 10. *Six dissimilar breeder Tulips, two in each class.*—First, Mr. Bentley with Elizabeth Pegg and Beauty of Litchurch, byblæmens; Rose Hill and Annie McGregor, roses; Sir Joseph Paxton and Lloyd's 47, bizarres. Second, Mr. Needham with Rose Hill and Annie McGregor, roses; Bridemaid and Elizabeth Pegg, byblæmens; Goldfinder and Sir Joseph Paxton, bizarres. Third, Mr. Mellor with Adonis and Hepworth's Seedling, byblæmens; Annie McGregor and Mrs. Barlow, roses; Sir Joseph Paxton and William Wilson, bizarres. Fourth, Mr. Moorhouse with Bertha and Hardwick's Seedling, byblæmens; Rose Hill and Annie McGregor, roses; Sir Joseph Paxton and Excelsior, bizarres. Fifth, Mr. Wood with Elizabeth Pegg and Boardman's 1, byblæmens; Mabel and Rose Hill, roses; Sulphur and Sir Joseph Paxton, bizarres.

Class 11. *Three breeders, one of each class.*—First, Mr. Needham with Bridesmaid, Mabel, and Sir Joseph Paxton. Second, Mr. Bentley with Elizabeth Pegg, Hepworth's 9/64, and Lloyd's 47. Third, Mrs. Eyre with Bridesmaid, Mrs. Barlow, and Sulphur. Fourth, Mr. Moorhouse with Adonis, Mrs. Barlow, and William Wilson. Fifth, Mr. Mellor with Bridesmaid, Mabel, and William Wilson. Sixth, Mr. Wood with Ashmole's 126, Mabel, and Sulphur.

Class 10. *Single blooms.*

Bizarre Breeders.

- 1 Mr. Bentley with Goldfinder
- 2 Mr. Bentley with Lloyd's 47
- 3 Mr. Bentley with Dr. Hardy
- 4 Mr. Needham with Wm. Lea
- 5 Mr. Bentley with Sir Jos. Paxton
- 6 Mr. Bentley with Goldfinder
- 7 Mr. Needham with Lloyd's Seedling
- 8 Mr. Needham with R. Yates

Flamed Bizarres.

- 1 Mr. Needham with Samuel Barlow
- 2 Mr. Needham with Sir Joseph Paxton
- 3 Mr. Bentley with Masterpiece
- 4 Mr. Needham with Orion
- 5 Mr. Needham with Samuel Barlow
- 6 Mr. Bentley with Cyril
- 7 Mr. Eyre with San José
- 8 Mr. Bentley with Paul Pry
- 9 Mr. Needham with Joseph Lakin
- 10 Mr. Needham with Lord Stanley

Flamed Roses.

- 1 Mr. Needham with Aglaia
- 2 Mr. Needham with Mabel
- 3 Mr. Eyre with Annie McGregor
- 4 Mr. Needham with Aglaia
- 5 Mr. Bentley with Olivia
- 6 Mr. Eyre with Clio
- 7 Mr. Bentley with Collier's Seedling
- 8 Mr. Mellor with Mrs. Barlow
- 9 Mr. Wood with Triomphe Royale
- 10 Mr. Wood with Lady C. Gordon

Flamed Byblæmens.

- 1 Mr. Bentley with Talisman
- 2 Mr. Bentley with Talisman
- 3 Mr. Bentley with Trip to Stockport
- 4 Mr. Needham with George Edward
- 5 Mr. Bentley with Josephus
- 6 Mr. Bentley with Mrs. Ramsbottom
- 7 Mr. Bentley with Chancellor
- 8 Mr. Bentley with Hannah
- 9 Mr. Bentley with Queen of the May
- 10 Mr. Bentley with Adonis

Rose Breeders.

- 1 Mr. Bentley with Mrs. Barlow
- 2 Mr. Needham with Mabel
- 3 Mr. Needham with Mary Jackson
- 4 Mr. Bentley with Lady Grosvenor
- 5 Mr. Needham with Lloyd's 208
- 6 Mr. Needham with A. McGregor
- 7 Mr. Eyre with Industry
- 8 Mr. Mellor with Queen of England

Byblæmen Breeders.

- 1 Mr. Bentley with Elizabeth Pegg
- 2 Mr. Bentley with Thurstan's 212
- 3 Mr. Bentley with Talisman
- 4 Mr. Needham with Lloyd's Seedling
- 5 Mr. Needham with Elizabeth Pegg
- 6 Mr. Bentley with Ashmole's 126
- 7 Mr. Bentley with Wm. Parkinson
- 8 Mr. Bentley with Thurstan's 248

Class 13. *The Best Breeder Tulip.*—Mr. Needham with Rose Hill.

Butley Tulip Society.

June 8th.

THIS old established society held its seventy-fifth annual show at the Orange Tree Inn, Butley, near Macclesfield, on Friday, June 8th. The flowers were good in quality, and what was better still there were more exhibitors than usual. The date chosen for the show was rather too late for several of the growers, but it just suited Mr. Bentley, who took most of the prizes. As it is without doubt discouraging to smaller growers when one or two big men come and take all the prizes, it was unanimously decided that next year no exhibitor shall be allowed to take more than two prizes in each class. We hope that this new rule will have the effect of bringing more exhibitors, as there will be more chances of success for everybody. The judges, Messrs. Housley (Stockport), Whittaker (Royton), and Chadwick (Butley), made the following awards:—

Silver cup for the best stand of six rectified Tulips, one in each class.—Mr. J. W. Bentley, Stakehill, Manchester, with Sir Joseph Paxton, flamed, and William Annibal, feathered bizarres; Prince of Morocco, flamed, and Foster's Seedling, feathered byblæmens; Mabel, flamed, and Mrs. Atkin, feathered roses.

Three breeders, one in each class.—First, Mr. Bentley with Lloyd's 47, Alice Grey, and Rose Hill. Second, Mr. J. Hague, Stockport, with William Wilson, Janette, and Mabel. Third, Mr. A. Moorhouse, Wakefield, with Sir Joseph Paxton, Janette, and Mrs. Barlow.

Single blooms. Feathered bizarres.—First, Mr. C. W. Needham, Hale, Cheshire, with Magnum Bonum. Second, Mr. Bentley with William Annibal; third, with Samuel Barlow. Fourth, Mr. Needham with Sir Joseph Paxton. Fifth, Mr. Bentley with Jas. M'Intosh. Sixth, Mr. Needham with Typo. Seventh, Mr. Bentley with Lord F. Cavendish. Eighth, Mr. T. Buckley, Staleybridge, with William Wilson. Ninth, Mr. Bentley with Attraction.

Feathered byblæmens.—First, Mr. W. Dymock with John Hart. Second, Mr. Buckley with Couingsby. Third, Mr. Needham with Talisman. Fourth, Mr. Bentley with Mrs. Jackson. Fifth, Mr. Needham with Elizabeth Pegg. Sixth, Mr. Bentley with Bessie; seventh, with Martin's 117; eighth, with Bertha; ninth, with William Bentley.

Feathered Roses.—First, Mr. Bentley with Heroine; second, with Mrs. Atkin; third, with Miss Edwards; fourth, with Alice; fifth, with Sybil; sixth, with Mrs. Collier; seventh, with Julia Farnese; eighth, with Modesty. Ninth, Mr. Needham with Annie McGregor.

Flamed Bizarres.—First, Mr. Needham with Sir Joseph Paxton. Second, Mr. Bentley with Samuel Barlow. Third, Mr. Needham with Dr. Hardy. Fourth, Mr. Bentley with Merit. Fifth, Mr. Needham with Sir Joseph Paxton. Sixth, Mr. Bentley with San José; seventh, with Lea's Seedling; eighth, with Sulphur; ninth, with Lord Stanley.

Flamed Byblæmens.—First, Mr. Bentley with Adonis; second, with King of the Universe; third, with Talisman; fourth, with Adonis. Fifth, Mr. Dymock with Lord Denman. Sixth, Mr. Bentley with Malakoff; seventh, with Salvator Rosa; eighth, with Lady Franklin. Ninth, Mr. Buckley with Trip to Stockport.

Flamed Roses.—First, Mr. Bentley with Mabel; second, with Madame St. Arnaud; third, with Annie McGregor; fourth, with Mabel; fifth, with Hepworth's 25/62; sixth, with Tryphena; seventh, with Minerva. Eighth, Mr. Moorhouse with Aglaia; ninth with Rose Hill.

Bizarre Breeders.—First, Mr. Bentley with Lloyd's 47; second, with Goldfinder. Third, Mr. Needham with Dr. Hardy. Fourth, Mr. Moorhouse with Sir Joseph Paxton. Fifth, Mr. Hague with Lloyd's 216.

Rose Breeders.—First, Mr. Bentley with Rose Hill; second, with Mrs. Barlow; third with Mabel; fourth, with Annie McGregor; fifth, with Madame St. Arnaud.

Byblæmen Breeders.—First, Mr. Bentley with Surpass le Grand; second, with Martin's 117; third, with seedling 1/00; fourth, with seedling 2/00; fifth, Mr. Hague with Alice Grey.

Selfs.—First, Mr. Bentley with White Model; second, with Buttercup.

Premier Feathered Flower.—Mr. Bentley with William Annibal.

Premier Flamed Flower.—Mr. Needham with Sir Joseph Paxton.

Premier Breeder.—Mr. Bentley with Rose Hill.—J. W. BENTLEY.

Fruit Forcing.

Cucumbers.—Any pits or low houses that have been used for forcing Strawberries, Vines in pots, or wintering bedding plants may be utilised for growing a late supply of Cucumbers. The plants may be grown in pots 12 inches in diameter, or larger, draining them well, and only partly filling them with compost, so as to leave space for fresh additions, or they may be grown in shallow boxes or troughs about 18 inches wide, and 7 inches deep, they being easily improvised on the staging. A wood or other trellis may be provided with little trouble at about 15 inches from the glass. No fire heat will be necessary, the house being closed between 3 and 4 P.M., syringing then, and damping the floors and other surfaces in the evening, also in the morning, but not then syringing the plants, it often being the cause of great injury to the foliage. Admit a little air at 75°, and allow the temperature to rise to 85° or 90° with sun, and close early, never later than between 80° and 85°; if the temperature rise afterwards to 90° or 95°, or even 100° all the better. Train with a single stem to the trellis, rubbing off all laterals to that height, then allow them to grow, pinching the leader after it has advanced about two-thirds across the trellis. The laterals may be stopped one or two joints beyond the show for fruit, covering the trellis evenly without overcrowding.

In the Cucumber house fire heat will only be necessary to prevent the temperature falling below 65° at night and to insure 70° to 75° by day. Attend well to stopping the shoots, removing bad leaves, thinning the old growths, and watering with liquid manure about twice a week. Sprinkle some sweetened horse droppings on the bed once or twice a week to encourage surface roots, and occasionally a little soot may be used, both of which give a deep green colour to the foliage and fruit.

Pit and frame Cucumbers may be watered about 4 P.M., closing then, or earlier, according to the weather, but it is not advisable to close so early as to raise the temperature above 90° or 95°. Liquid manure may be given occasionally, but it is not desirable to apply it over the foliage, or too frequently. Keep the growths fairly thin, thinning out old shoots and encouraging others in their place so as to keep up a succession of bearing wood. Stop one or two joints beyond the fruit. Avoid overcropping and allowing the fruit to remain on the plants a day longer than can be helped. Shade only to prevent flagging, and admit a little air early as a safeguard against scorching.

Vines.—*In Pots.*—Stop those for fruiting next season when from 6 to 8 feet in length, and pinch the laterals and sub-laterals to one joint as produced. Obtain as much stored up matter in the Vines as possible by judicious feeding and cleanly foliage fully exposed to light and air. Vines intended for planting should be kept in comparatively small pots, and in that case they will not make a large amount of lateral growth which need not be closely pinched, but it is better to stop at the first joint, and afterwards not allow the sub-laterals to interfere with the principal foliage.

Late Grapes.—These must be thinned immediately they are large enough, the berries swelling so rapidly at this season that they soon become too large to be thinned properly and expeditiously—besides, when the work is deferred too long the size of the fruit is impaired. The laterals must not be allowed to extend so as to interfere with the principal foliage. The growth may be permitted to extend where there is space for its full exposure to light, but not otherwise, as overcrowding and overcropping are often the causes of indifferent results, and more frequently so than any other error of culture. Remove all superfluous, badly placed, deformed, or small bunches. Crop lightly, which means size, quality, and high finish; bulk signifies small fruit, bad colour, poor quality, often shanking, and always non-keeping. Water thoroughly when necessary; one good watering is worth many dribbets. Afford top-dressings of chemical manures occasionally, and a light mulch of sweet lumpy manure will prove beneficial in most cases by encouraging surface roots and maintaining uniform moisture.

Grapes Scalding.—Muscat of Alexandria and Lady Downe's are more liable to "scald" than most other varieties, but Hamburgs, Gros Maroc, and even Alicante sometimes suffer severely when completing the stoning process, and in some seasons at a much earlier stage, this year being one of them, we having received examples at thinning size and also when swelling fast after thinning. The only preventive is early ventilation, as it is keeping close, moist, and cold that renders Grapes liable to scald if the weather prove bright. In the early stages a temperature of 60° to 65° at night, 70° to 75° in the daytime, leaving a "crack" of air at the top of the house at night, and increasing the ventilation by or before the sun acts powerfully upon the house, is a certain means of avoiding scorching and scalding. When the Grapes are about completing the stoning process, and from then until they are advanced in colouring, air should be given abundantly, sufficient warmth being kept in the hot-water pipes to maintain a night temperature of 65° to 70°, and 5° to 10° more by day, leaving venti-

lation on at night, and increasing it before the sun acts powerfully upon the house in the morning.

Grapes Ripening.—Afford these a free circulation of air on all favourable occasions, with enough constantly to insure a change of air, as it is a confined atmosphere that does the mischief in Grapes "spotting" and "cracking." Keep sufficient heat in the pipes to maintain a night temperature of 65°, and 70° to 75° by day, with 80° to 90° through the day from sun heat. Avoid a very dry atmosphere, damping occasionally, and do not allow the border to become dry. Moderate lateral growth will favour Hamburgs and Madresfield Court, but Muscat of Alexandria colours best when exposed to the light, yet a little lateral growth is desirable as a safeguard against shanking and for the maintenance of healthy root action.

THE BEE-KEEPER.

Work in the Apiary.

ALL is now activity in the apiary, the majority of colonies are in good condition, and if we are favoured with fine weather for a month or six weeks, bee-keepers will have no reason to complain of the result of the honey harvest. Stocks are not as forward as usual, as dull weather and cold winds were experienced throughout the month of May, and it was only those colonies which received careful attention during that time that are now storing a surplus. It is many years since there was such a wealth of blossom as during the past few weeks. The different fruit trees have all flowered well, and only a few of the late flowering Apples remain. Many of our forest trees have bloomed much more freely than is usual. The Thorns are now a sheet of bloom, and the bees will derive a much greater benefit from the May than if they had flowered earlier.

Field Beans are now in bloom, and should they be within two miles of the apiary the bees will work much more freely on them than on any other flowers open at the present time. The honey obtained from the above sources when mixed is brown in colour, somewhat coarse in the grain, but of good flavour. Attention should be given to all stocks on the lines mentioned in previous notes. Colonies that were too weak a fortnight ago for supering ought now to be strong enough. Honey is coming in freely, and if this operation is delayed much longer less honey will be stored than if they had received attention at the right time.

Bees Swarming.

Although the modern bar frame hives have to a certain extent done away with the system of increasing the number of stocks by allowing the bees to swarm, we cannot hide the fact that there are numerous stocks in straw skeps in various parts of the country. With these swarming is a necessity, and the earlier the swarms are obtained the greater the chance of obtaining a surplus. In our own apiary we practise both systems. As bees invariably winter well in straw skeps it is often an advantage to have some early swarms. Swarms work well, and if obtained early a surplus may be procured from them.

The earliest swarm in this district (South Yorkshire) came off on the 27th of May. The warm weather experienced on the 3rd and 4th inst. caused many bees to swarm. These, if well managed, will give a good account of themselves. Should the weather become dull and cold such swarms must be fed with thin syrup.

Where frame hives are at hand it is advisable to place the swarms in them. It will be an advantage to give them full sheets of foundation, and not more frames than they can cover well; six frames will be ample for an ordinary swarm weighing about 4 lbs. The division board should be placed close up, and as soon as the cells are all drawn out another comb may be inserted in the middle of the brood nest. This can be repeated as often as may be considered necessary. If the honey season is likely to be a short one it will be an advantage to keep the brood nest reduced, and place a crate of sections on the top of the frames. If honey is coming in freely the bees will commence to store a surplus at once.—AN ENGLISH BEE-KEEPER.

Leaving Sections on in Winter.

WHILE agreeing with "An English Bee-keeper" on general topics, as to the desirability of putting sections on when "honey is coming on freely," I may say that in several cases which have come into my hands to manage I have found crates of sections filled and ready to take off (before the bulk for the season had been put on) from leaving on through the winter, and with very little covering. I have already taken off some beautifully filled sections from a crate left on all the winter, which, if I remember rightly, the bees did not enter last summer, although "honey was coming in freely" at the time I put them on just in the Clover harvest. So we have to "live and learn" from experience.—J. HAM.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Thinning Grapes (I. F.).—An article on this subject will appear in an early issue, probably next week.

Peaches Mildewed (A. A. T.).—The spots on the Peaches should be rubbed with flowers of sulphur, and the trees afterwards dusted in every part, preferably by means of a bellows apparatus. This must be done without delay, as the skin once injured by the parasite seldom heals over, or a dark patch is formed and the fruit swells irregularly. It is desirable to allow the sulphur to remain on for a few days before again having recourse to syringing. The mildew is induced by a cold and dry condition of the atmosphere, especially cold draughts, the conditions prevailing this spring being favourable to the fungus.

Tomato Leaves Diseased (*Idem*).—The leaves are infested by the spot fungus, *Cladosporium fulvum* or *lycopersici*, which is usually due to a close and somewhat moist atmosphere. There is no trace of the Potato disease fungus, *Phytophthora infestans*. The remedy is to, in the early part of the afternoon of a fine day, allow the temperature to rise to 100°, or even 110°, the latter being fatal to the parasites, and the Tomato plants are not materially prejudiced. The house should be kept close for a couple or three hours, and then air admitted, so as to allow the heat and moisture to escape. It is necessary to maintain a buoyant atmosphere, ventilating early in the day, or rather increasing it, for a little should be left on constantly at the top of the house, and this with a gentle warmth in the hot-water pipes in dull periods will prevent a stagnant atmosphere. The worst infested leaves should be removed and burnt.

Vines Cleared of their Crops (*Young Gardener*).—Syringe the Vines occasionally to keep the foliage clean, afford water to render the soil moist, and supply an occasional top-dressing of fertiliser. A light mulching will keep the soil from cracking, as well as prevent the roots going down in quest of moisture. Allow a moderate extension of the laterals, but do not permit them to interfere with the principal leaves. Some lateral extension is absolutely necessary to prevent the starting of the main buds and the premature ripening of the foliage. There is no fear of the wood not ripening, the difficulty is in the opposite direction—loss of foliage and starting into growth instead of going to rest in late summer. Ventilate freely when the temperature rises above 60°.

Carnation "Grass" Diseased (J. J.).—The "grass" is affected by the complaint known as "withering," the leaves dying back from the points or edges, or even from the base. In some cases there is present the spot fungus, *Septoria dianthi*, but in many the microscope does not reveal even so much as a trace of this or another harmful agent. For this reason the disease has been held to be constitutional. The best, and, indeed, only remedy and preventive is the prompt removal of affected plants and burning them. Spraying with diluted Bordeaux mixture has been advised, but the application spoils the appearance of the leaves. The better way is to accord such treatment as conduces to a sturdy habit. In the case of plants liable to have weak "grass" a pinch of common salt applied occasionally to each 6-inch pot, sprinkling on the surface and washed in as in the ordinary course of watering, tends to solidify the growth and render it more disease resistant, not applying more frequently than every six weeks.

Spots on Vine Leaves (S. S. H. Wight).—The spots are occasioned by a very mild form of the Grape anthracnose fungus, *Sphaceloma ampelinum*. As the fungus progresses the growth of the leaf is checked, the parts withering or sometimes falling out, leaving the leaf in holes, or in bad cases the leaves wholly wither. The fungus attacks all the green parts of the Vines, and the light-coloured and white Grapes are the ones most affected, but it seldom infests the berries in this country. The fungus has been successfully prevented on the continent by dressing the Vines early in spring, before the buds start, with a solution of copperas (iron sulphate), 1 lb. to a gallon of water, applying with a brush to the rods, canes, and spurs. In case the disease appears a powder composed of equal parts of sulphur and lime may be dusted on, and this we advise at present, applying with a bellows apparatus such as the Malbec. The advertised fungicides in powder are also good for the purpose. A free admission of air, especially in the early part of the day without causing draughts, with gentle warmth in the hot-water pipes, so as to maintain a circulation of air, and prevent the deposition of moisture on the green parts of the Vines, is useful in preventing the development of the spores of the fungus, as well as fortifying the epidermal tissues against the inroads of the parasite. As the foliage is thin and light coloured we should use a little fertiliser, selecting from the advertised preparations and applying according to the instructions.

Acacia grandis (H. Browne).—This is a very dwarf West Australian species, and flowers freely when small. It is a most charming window plant for spring flowering, being at that season loaded with its golden yellow balls, and at all periods of the year its elegant foliage gives it an ornamental character. Its propagation is effected either by seeds or

FIG. 140.—ACACIA GRANDIS.

cuttings, usually by the latter method; they should be inserted in white sand or very sandy soil, and covered with a bell-glass or tumbler. As they are impatient of damp they require a little more care during the rooting process than those of the leafless species; the inside of the glass should be wiped daily, and as soon as the cuttings are rooted they must be potted in sandy peat, and eventually in good fibrous peat, containing less sand.

Stephanotis floribunda (*Amateur*).—Although this plant does not need shade, a slight covering is beneficial during the hottest part of the day through the flowering season. It prevents the flowers opening too rapidly, and they also last in good condition for a longer period. Plants that are trained under the roof and are growing rapidly should have the young shoots drawn out and allowed to hang down. Some attention is needed two or three times a week, or the shoots soon become twisted together. This method allows of the main shoots being trained more closely under the roof. The shoots that hang from the roof flower profusely, and the plant can be kept much cleaner by a free use of the syringe than when the whole of the growths are closely trained together under the roof. From the present time plants that are in full activity should not be kept too warm, close, or moist. A temperature of 60° at night will be ample with a liberal application of air during the day, this will insure firm growth that will flower well. If the plants are grown in pots and crowded with roots a surface dressing of decayed manure will prove beneficial.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (A. W.).—1, *Spiraea confusa*; 2, Send when in flower; 3, *Thunopsis Standishi*; 4, *Cedrus atlantica glauca*; 5, *Cedrus atlantica*. (C. P.).—The Rose is the Austrian Copper Brier; the blue flower is *Scilla peruviana*. (J. L. S.).—1, *Limnanthes Douglasi*; 2, *Phlox amena*; 3, *Saxifraga ceratifolia*; 4, *Lonicera sempervirens*. (J. E.).—1, *Saxifraga muscosa*; 2, *Spiraea arguta*; 3, *S. hypericifolia*; 4, *S. confusa*; 5, *Ercilla spicata*. (B. C.).—1, *Ginkgo biloba*, the Maidenhair Tree; 2, *Taxodium sempervirens*; 3, *Cupressus Lawsoniana erecta viridis*.

Too Tasty.

A FLAVOURLESS article of food is poor, insipid eating. There are far too many cooks who fail in the art of seasoning. They will make hashes and stews and meat pies that appear to be absolutely guiltless of salt or pepper, and then at the same time they will sadly overdo the spice pot in the matter of delicate dishes that take flavouring all too easily. What they lack is judgment; they have not well balanced minds or the gift of proportion. There are likes and dislikes in the matter of seasonings and flavour, but we fancy most of us are at one on the subject of our milk and butter—possibly it is that because to have butter and milk with any flavour except the pure milky taste is an offence against the canons of good taste!

We are writing on the evening of June 1st. Business led us to the butter market of a great city. Butter was raling from 7d. to 9d. per lb. of 16 ozs., and late in the day much was still on sale. Some was certainly oily looking and messy, other lots looked as fresh as though just out of the dairy. One young man was standing penknife in hand, offering tastes of his wares to passers by; we were invited, but the penknife was not tempting, and we thought the young man affirmed too much. Many of the market women bring with them huge bunches of "Laylock" and other strong smelling flowers—Lilies to wit—also herbs of all sorts, particularly the flavouring varieties, and these travel in close proximity to the butter. By afternoon the atmosphere of the butter market is—ahem! The women need refreshment, and in the centre is a stall, plenty of hot tea and cakes of all descriptions. Add to this a packed crowd, baskets of poultry, the flowers and the herbs, and you get as grand a mixture as you can wish for. Did not Douglas Jerrold say there were seventy-nine distinct smells in Cologne besides the celebrated water? We wonder how many he could have counted to-day, and the cold N.E. wind was blowing strongly. Fancy how it would be with a high temperature and soft genial breezes. We went from the butter market into the Free Library, where an elderly market woman was devouring "Truth" (Labby's, we mean), and close under our nose was her packet of provisions. We sniffed once—that was enough—we detected not the bread but its accompaniment, and we did *not* want to go home with her to tea.

There is blame somewhere—there is cause or causes for this condition of things. Some of the causes are preventible, others are not so. As milk is the foundation of all butter, we will go to the fountain head—the cow. Is she in good health? Is there any germ of disease about her? At what stage of milking has she arrived? The first few days after calving her milk partakes of a medicinal character, Nature's own provision for the good of the calf; such milk should not be set for cream. Then again, when she is getting stale the milk loses some of its good properties, and will not make the best of butter. What about the housing, the feeding, and the general surroundings? There are many cow houses no inspector ever sees, and it might be awkward for the owners if he did. The old idea of closeness and warmth is not exploded yet. Have warmth by all means, but let there be fresh air with it. The New Zealand plan of rugs for cows is not at all a bad one; it might make the cow-keeper less fearful of a pleasant breeze.

The water supply should be purity itself. Is this always so? The food varied—wholesome and not too strong flavoured Turnip tops; outside leaves of Cabbage and the like are not desirable. A Garlic or Onion eater is not good company at close quarters as we all know. At this time of the year we are or ought to be free from

any anxiety respecting the cow's diet. She is turned out on to the fresh young grass, which the genial sun has caused to spring up on all sides. The day of hand food is over. She selects her own salad. Well, poor thing, the outlook to-day is not very grand. A prolonged spring, not a poet's spring, but like one described by Dickens, is still with us, not a feature of summer, unless we except the drought, herbage scanty, and bitter nights—not at all ideal weather for the secretion of milk. The cow must eat; she has a big frame to support, and therefore she picks about here and there, and like the locusts devours every green thing that comes in her way. At night she vainly tries to seek shelter under hedgerows or trees, the very worst places to find sweet and wholesome food. She will be very lucky if she does not get hold of some strong flavoured morsels. She will lose condition herself, and the milk suffers at once. If pastures will not grow weeds will. Not only weeds will attract, but sundry and divers buds and shoots on hedges and trees—some may be wholesome, others very undesirable. Some of our readers will recall a passage in a novel of modern days by a well-known writer, wherein is described the consternation of a dairyman who finds his milk Garlic-tasted; how all the men and maids (and an angel) were sent out with spuds or knives and took every inch of pasture ground. It was a slow and expensive process, but it was that or loss of milk customers. We have never had Garlic in our own pastures, but found a patch once hard by the gate of one of the home fields, where cows passed daily. There is practically no means of removing the taint from the milk when once there. The only way is by efficient refrigeration to prevent it getting worse. Passing the milk twice over the refrigerator will also aerate or oxygenate it.

But there are many ways by which milk becomes tainted that are quite preventible. It is the old story of cleanliness; we are always preaching it till our readers will tire, but until our noses give us direct evidence to the contrary we must stick to our old text. It is no use to assert butter and milk are sweet and good if the evidence of the nose is against it. Boiling water, not hot, scalded utensils well purified by the breath of Heaven, are the main factors. Listen to a few directions respecting the pails. First rinse in warm water, then clean inside and out with a brush and hot water, using some soda if necessary, and afterwards scald with boiling water, and leave exposed to the air in a clean place. No use to put clean vessels where there are foul odours. Strainers, defective pails—i.e., badly made, with rough joints, or even little holes—are all sources of danger. The scrubbing brush and washing cloths are often themselves in need of cleansing, and are frequently, alas! neglected. It goes without saying that the water must itself be pure and fresh.

To enter upon the question of the actual manufacture of the butter would require too much space. To minimise labour cream is often kept far too long. Overripe cream can never produce first class butter. Supposing the butter churned in a perfectly clean wholesome churn, then comes the task of freeing from buttermilk and working, not too long. It is quite a usual fault with amateurs to be too anxious. They work their butter so long and so zealously that it becomes "oily" and "salvy." Others again are not careful to get rid of first the butter milk, secondly the water that has been used to wash. That is all very well if customers can be persuaded to buy butter, milk, and water at so much per ounce; but the butter will not be good, and therefore will not command a first-rate price.

It is no use to make good butter and then spoil it by contact with strong smelling articles, or by keeping it in an unwholesome place. It is want of care in small details that does so much to spoil our butter as a whole. It is the old story of "for want of a nail," and we cannot wonder that the English farmer loses his butter customers when we find how often the article is "too tasty."

Work on the Home Farm.

The wind still keeps in the north-east, and we have very little sunshine. Crops are not suffering exactly, except from the fact that they are losing time, and harvest is being put further back day by day. Many farmers are crying out for rain, but all long for more sunshine

and warmth—some of last season's heat. Can the heavy expenditure of powder in South Africa have affected our weather? We have heard it suggested.

More local examples of Charlock spraying keep coming under notice. Sulphate of iron is used in some cases in place of sulphate of copper. It is cheaper, but requires a much stronger solution to be effectual. It is said to do less injury to the young corn shoots, whilst being quite as effectual on the Charlock.

There has been rather a serious loss amongst young calves lately. Some farmers invariably lose calves in the spring, and seem to expect it, but this time the loss has been more general, one old neighbour, usually lucky, having lost a dozen. We fancy the flush of grass has much to do with the scour which causes the mortality, the active reason for the scour being overfeeding. More calves are killed by having too much milk than by having too little. Alternate doses of cholera mixture and castor oil are the only medicines worth using.

The scarcity of labour will no doubt have a tendency to induce farmers to sow Turnips on the flat where ridging has been usually practised. On some soils flat drilling is desirable on account of the greater certainty of getting a plant in dry weather, but we do not like putting large quantities of artificial manure in, with or immediately underneath the seed. For one thing, the residuary influence of this manure is apt to show itself too much in a sort of ridge and furrow appearance in the next crop, and we do not think the young Turnips are benefited by the near presence of a highly concentrated manure, especially a nitrogenous one. We should prefer broadcasting the manure either by hand or drilling.

Potatoes must be earthed up as they become ready. Very large growers use a light one-horse plough, and go over the ground twice, a horse hoe set very narrow being run between the ridges before the second earthing. Old ewes will now pay for a bit of cotton cake; what is not repaid in milk for the lambs will give a return in mutton, which is not likely to be cheap this season. A pen should be arranged with hurdles, to which the lambs only have access, and they can be treated and educated to a little choice mixture of lamb food whilst their dams are discussing the coarser material.

Prices of Sheep.—In the prices of fat sheep in London, the record of the year and several recent years was broken recently, when wethers sold up to 9½d. per lb., carcase weight, sinking the offal. But for some weeks the top price has been higher at Liverpool than in London, 10½d. per lb. having been the top price all through May in the latter market.

Winter Feeding of Cows.—A discovery which caused some surprise to the Newtonrigg officials was made in connection with some experiments on the winter feeding of cows. The rule at the Cumberland Farm School is to discontinue cake when a cow's yield of milk sinks to a gallon a day. During the very severe weather of December it happened that the housed Swedes were used up, and the snow prevented the bringing of others from the field. As a temporary expedient Mangolds were given to the cows for a week, but only to half the extent that Swedes had previously been supplied. The resultant manure was very much softer, as was anticipated, but quite unexpectedly the milk yield of the whole herd rose, although the weather was very cold and wet; moreover, the supply has continued higher than would have been looked for from cows on the natural decline in milk yield. Mr. Lawrence therefore concludes that the medicinal effect of the Mangolds on the cows which had been under liberal treatment for winter dairying was to put the system of the animals into better working order, and thus improve milk secretion.

Manuring Hops.—The results of Dr. Bernard Dyer's elaborate experiments in the manuring of Hops have demonstrated the fact that nitrate of soda is a particularly effective manure, and large quantities of it have been employed with profitable results and without apparent evil effects. As much as 10 cwt. of this foreign manure has been used on 1 acre with beneficial consequences, the profits from this heavy allowance exceeding those obtained from the light dressings from 2 cwt. upwards. Dr. Dyer does not advise the continuance of nitrate of soda on this lavish scale, however, but considers 4 cwt. per acre a safe and serviceable dressing for general use. He is emphatic in urging the early application of manures of this class. Contrary to the theory advanced in some quarters he holds, and has confirmed his contention by practical demonstration, that the crop utilises and appreciates the manure best in its earlier stages of growth. The manuring process should begin as soon as vegetation starts in spring, and be completed by the end of May at the latest. Another point strongly enforced by Dr. Dyer is the necessity of applying a liberal dressing of a phosphatic manure in any circumstances, with or without farmyard manure, and independently of the form of nitrogenous manure employed. For calcareous soils he recommends 8 cwt. per acre of superphosphate, but for soil lacking in lime basic slag, bone dust, or guano would probably be better. For medium land superphosphate and one or other of the other substances named should be used in alternate years. Potash salts are not requisite when farmyard manure is used, but should be included when artificials only are available.—("Morning Post.")

A Triumph in Hybridisation. Unique Offer.

3 NEW PASSION FLOWERS ALL DISTINCT.

Exceeding in beauty all others. Delicately Perfumed. Free Blooming.

Raised at Oldfield Nurseries, Altrincham.

PASSIFLORA CLIBRANI.

This beautiful distinguished hybrid cannot be too highly commended. We claim it to be the ideal of all the Passion Flowers, it being a most distinct and handsome variety after the style of Princeps, but far excelling this variety. The petals are of a rich red wine colour, always so attractive, rays of corona chocolate tipped with white. A charming flower in every respect. Perfectly free and vigorous.

PASSIFLORA FRAGRANT BEAUTY

As the name truly implies, this variety possesses a fragrance perhaps exceeding that of any other variety. A plant now in bloom at our Oldfield Nurseries commands the admiration of all visitors on account of the delicious perfume. The petals are pure white, rays of corona in two circles, centre chocolate brown, zoned white in the middle, upper portion bluish purple shades. Charming contrasts. Profuse bloomer.

PASSIFLORA OLDFIELD GEM.

This excellent hybrid possesses very considerable merit. It is a distinct handsome and free variety. The flowers are very large, and what has been said of the perfume of *Fragrant Beauty* we reiterate respecting this magnificent gem. The petals are pure white, delicately netted rose. The rays of the corona are in two circles, and being of a wavy outline they greatly enhance the appearance of the flowers. Centre rich velvety maroon, clear white zone, upper portion purplish violet.

Price 2/6, 3/6 & 5/- each; the set of three, 6/6, 9/- & 13/-

CLIBRANS', ALTRINCHAM.

BEGONIAS FOR BEDDING.

H. J. JONES' unrivalled strain in great varieties of colour, erect, vigorous, and free flowering; good stuff, ready for planting. Singles, 4/6 dozen; 50 for 16/-; 100 for 28/-. Doubles, 6/- per dozen.

FOR CASH ONLY.

The Season of Flowering Trees.

THE extensive planting of flowering trees and shrubs in pleasure grounds is practically a modern custom. If you wander through an old time garden that has never been renovated or added to, the chances are that you will find a wealth of green, fine ornamental trees of the Conifer class, with perhaps some variegation in foliage, but little bloom beyond that provided by the Chestnuts, Limes, and trees of similar character. The old landscape gardener had a tendency to cover the walls with Wistarias, Magnolias, climbing Roses, and the rest, but with him the shrubbery garden was the place for foliage alone, and few flowering trees had a place there.

Possibly there are several reasons for this, but one is that he had not the material at his command. The flowering trees and shrubs which we now possess are mostly modern creations which have been introduced during recent years, and by their advent they have brought about material changes in the formation and appearance of pleasure grounds. Nor have they taken the place of older ornamental trees, for the green adornments of the garden are as popular as ever they were, but the flowering trees break down the monotony of the everlasting green, brighten the sombreness of it all, and add a ray of showy colour which is rendered more delightful by the presence of the verdure. If evidence is wanted of this, go anywhere you like where a new garden is being made, or an old one renovated, and I venture to assert that flowering trees and shrubs will be well represented. They are prime favourites, these trees that bloom, and have worked their way into gardens fashioned centuries ago, where they are as much appreciated as in the small enclosure which surrounds the modern villa.

Evidence is not wanting to show that if the landscapist of a past decade had been furnished with this material, he would have used it with advantage, and it was more from necessity than choice that his shrubberies were evergreen. The

CLEAN HEALTHY PLANTS AT LOW PRICES

Always worth a visit of inspection. Kindly send for Catalogue

NEW LIST NOW READY.

JAMES CYPHER,

Exotic Nurseries, CHELTENHAM.

EPPE'S SELECTED PEAT

For Choice and Hardwood Plants, Ferns, &c.

Also for Rhododendrons. Specially selected for Orchids. Superior Leaf Mould, Y.F. Loam, Cocoa Fibre, Coarse and Fine Sand, Charcoal, Sphagnum, and General Garden Sundries. Prices and railway rates on application.

EPPE & CO., F.R.H.S., RINGWOOD, HANTS.

other day, when walking through a nobleman's garden, I observed some gnarled old relics of the common white Hawthorn, resplendent with pearly "May" blossoms. I learned that many years ago, when the hedges in the fields were broken up to form the garden, Thorns here and there were left standing for the sake of their flowers, and to-day they remain worthy ornaments of the garden, though only trees of the hedgerow; and I venture to assert that if the scarlet and crimson Thorn had then been obtainable, they would have been represented as well.

Just now, the first week of June, the garden is more beautiful than it can ever be again this year, for the simple reason that the trees and shrubs are blooming. Our bedding plants have yet to come on. Roses are only in bud, and there is a succession of herbaceous flowers to carry us through the season; but just now the trees and shrubs provide the show, on a scale gigantic and gorgeous. I will not attempt to particularise the many trees and shrubs which help to make the garden so beautiful at this season of the year. They are common most of them, and well known, though one is at a loss to understand why they are not more widely planted.

Take the Lilacs for instance, purple and white. They have long been popular, and no flowering plants are more worthy of a place in the shrubbery garden than these. Charming to look at, sweet to smell, they are amongst the floral gems of closing May and early June. They are seldom out of place, and are admirably suited for planting as a background for borders of herbaceous plants and low ornamental shrubs. They are common it is true, and so is many another flower that is altogether indispensable.

Then there is the yellow Laburnum, now so gay with flower. Could any pleasure ground be considered complete where it is not represented? I doubt if there is any other tree so effective as this when clustered with its bunches of golden yellow blossoms. Look at it in the distance when the evening sunlight plays on the blossoms. Let a bank of green form the background, with a sombre Conifer on this side and that—the golden Laburnum shines out from its canopy of verdure with a show of grace and splendour, and you realise at once the effectiveness of a combination of flowering and evergreen trees.

I have already spoken of the white Hawthorn which is allowed a place in some gardens, and is now beautifying miles of hedgerows in every county. Looked at from any point of view I doubt if we shall find any tree more beautiful when in full bloom than the wild Hawthorn of copse and woodland. It is perhaps because it belongs to the woodland that it is debarred from many gardens, but we have the double crimson and pink forms now full of blossom, rather more aristocratic, and well suited for garden adornment. Perhaps no one forms a shrubbery border nowadays without including a few of these double Hawthorns, and I should like to see more of them. The bright crimson is a colour quite unique, but when planting these trees there should be no crowding up in corners and places where there is no room for expansion. The crimson Thorn makes a fine specimen, and when standing cut alone on a lawn or elsewhere.

Another flowering tree, none too often seen in shrubbery borders, is *Pyrus malus floribundus*. Its full beauty is seen just before the flowers are quite expanded, and the crimson of the petal tips are then seen to perfection. The blooming capacities of this tree are remarkable, and this possibly keeps it from developing quickly into a large specimen.

I would say a word, too, in favour of coloured foliage trees, which, year by year, become more popular. There is still too much sameness in our shrubberies, and we want more colour in the shape of Copper Beeches and Hazels, Golden Elders, *Acer negundo variegata*, and the richly tinted Japanese Maples. These and other coloured foliage trees are now bright and beautiful in their summer garb; the flowering trees, of which I have only mentioned a few, as well as the large family of shrubs, including the Rhododendrons, Azaleas, Berberises, are all now playing a part in making June time the brightest month in the garden year.—G. H. H.

Rock Gardening.

MANY of the lesser but most beautiful of our alpine and herbaceous plants, whilst growing, perhaps, fairly well in the ordinary borders, never appear to advantage in that position, and without constant curtailment of their more aggressive neighbours are often doomed to disappear in the struggle for existence. Some of these are essentially rock plants whose habitat is the clefts and crannies of the natural rock; others are so eminently adapted to the same associations that their claims to a similar position may well receive the consideration they deserve; and the whole comprises such variety, interest, and beauty that a rock garden, even of the simplest kind, forms a particularly pleasing feature in any garden.

To many the making of rockeries is contemplated as a somewhat serious matter, one not to be lightly undertaken, hence it is often not undertaken at all. Especially is this the case with those whose artistic taste and cultured eye beget an abhorrence of anything pertaining to a sham resemblance of Nature. That it is so is not a matter for surprise when evidence exists of ambitious attempts resulting only in glaring absurdities, as ill adapted to the lowly life of an alpine as they are to adorn a garden, and the initial expense incurred must, too, be included.

In rock gardening the welfare of the plants with a more natural disposition of them than usually obtains should be the first consideration, and the simplest arrangement of any stones peculiar to the locality is the safest and most satisfactory means to the end in view. No happier example of its kind could be seen than the rock garden at Mrs. Gibson Black's pretty residence, Clontarf, co. Dublin. It must, indeed, prove a revelation to many whose acquaintance with the subject is practically limited to the orthodox planting in bed or border. Some considerable portion of an old-fashioned garden has here been devoted to the subject; and though the whole may be seen at a glance on entering the enclosure formed by a thick hedge on one side, and a wall on the other, hours may be spent in wandering through the informal walks which intersect the spacious area forming such a brilliant *coup d'œil* at the time of our visit.

It was the time of Tulips, Gesneriana, and macrospela in glowing masses of colour being conspicuous in the background of the rock-bound beds, whilst ever and anon clumps of the pure self-coloured Darwinia enlivened the scene. The exact width of these informal beds cannot be given, but they appeared to be of such dimensions as facilitated the operation of weeding from either side without treading upon them. Beyond an occasional weeding a rock garden of this description when once formed and planted appears to involve no further labour save such labours of love as are entailed by the introduction of newcomers to the happy family, or some little attention to particular favourites. The edgings to the beds are formed by stones keeping within bounds the soil raised above the level from 1 to 2 feet, through which other stones are irregularly distributed.

At the time of our visit the prostrate growing Phloxes, represented by *P. Nelsoni*, *P. frondosa*, and others, were sheets of bloom, whilst similar habited plants comprising Saxifragas, *Tymuses*, the lesser Campanulas, with many choice alpine, often appearing to exist only on sufferance elsewhere, formed undulating cushions of luxuriant health and surpassing beauty, to those at least who love these floral gems. Though irrelevant to our subject, mention must be made of a large specimen of the Magnolia-leaved Laurel seen in the pleasure grounds, but other objects of interest apart from it are reserved for future notice. In a momentary return to the text, some choice bits of alpine must be noticed which have been comfortably accommodated with pockets on the cool side of an old wall. The pleasure of our visit was much enhanced by the intimate knowledge of the subject displayed by Mr. Humphreys, Mrs. Black's able gardener, and further still by the company of a friend who dearly loves an argument over such matters in which he is keenly interested, but who had, fortunately, left his shillelagh at home.—K., Dublin.

**Dendrobium Dalhousianum.**

At the meeting of the committees of the Royal Horticultural Society, held in the Drill Hall on the 5th inst., Orchids were not very numerous; indeed, they were not expected to be, following so closely upon the Temple Show. There were, however, several plants of exceptional interest, and amongst these must be included the hybrid *Dendrobium Dalhousianum*, of which a flower is represented in the illustration (fig. 141). It will be seen that in the new corner, whose parentage is made quite clear in the specific name, we have the colour and size of a good variety of *D. nobile*, while the presence of *D. Dalhousianum* is shown in the flattened lip and the strength of the plants. *D. Dalhousianum* was exhibited by Mr. W. H. White, gardener to Sir Trevor Lawrence, Bart, Burford Lodge, Dorking, and was recommended for an award of merit by the Orchid Committee.

Cattleya citrina.

We have few *Cattleyas* that vary so little in colour as this fragrant species. The only variations I have seen are a whitish margin to the lip in some flowers, and a dull brown tinge to the petals in others. This may be owing to the absence of bright colours on the labellum, as when growing wild bees and other insects are attracted by these colours on many varieties and cross fertilisation thereby effected.

Some persons have expressed a doubt as to whether this *Cattleya* can be successfully grown in an upright position. There can be no reason why it should be so grown. To keep *C. citrina* in health frequent spraying is very helpful, and Nature has provided a means whereby the superfluous water is carried off. The flowers, too, are shown to greater advantage when growing naturally. After flowering this species should, if possible, be induced to rest awhile by keeping cool and rather dry at the roots in the *Odontoglossum* house. When it is seen to be starting into growth the cool end of the *Cattleya* house is the best position for the plants. Here they may remain until the flower sheaths appear, usually early in the new year, when cooler quarters will again be advisable.

C. citrina will grow well on bare charred blocks or on blocks lightly dressed with sphagnum. They must be wired on firmly, and look best if suspended at an angle corresponding with the roof of the house in which they are growing.—H.

The Phalaenopsis at Home.

It may be of interest to growers to know under what conditions the *Phalaenopsis* grow best in their native land, so that a method of cultivation which will suit them best may be afforded. Newly imported plants are the best for cultivation. It is often the case that plants, which succeed well with one grower, will give an entirely different result if transferred to another place, and from this standpoint fresh imported stock is to be preferred.

In order to give the grower a proper idea of the climatic conditions of the Philippine Islands, I think it best to describe their situation. These islands extend from the 5th to the 18th degree northern latitude; they are bordered on the east by the Northern Pacific and on the west by the China Sea, being visited by north-east winds from October till May, and from south-west winds from May till October. Both winds carry rain with them, which reaches the parts of the islands nearest to them. While one side has rain, the other is absolutely dry. The limit of these rains is the mountains which traverse the islands from south to north; but it would not be right to think that the rains do not pass this limit, all depending on the force of the wind. Through these circumstances the mountains have a continuous moisture, more or less, according to the winds; and in the valleys of this region grow the *Phalaenopsis*. I do not want to say that it pours continuously in these valleys, although it happens that during a typhoon the rain will last for fourteen days. Otherwise rain is about the same as in Europe, only that the rainy period is steady for a few months. There are also very hot days, oftentimes weeks, without any rain whatever.

To speak again of *Phalaenopsis*, I will say that these plants are found especially on the driest places, and only grow on the highest branches, where the winds and the sun rays can strike them best; on low branches and on the lower stems of the trees *Phalaenopsis* are rarely found. The want of air and light and too much moisture soon kill the plants in such places, and on this account few large plants are to be found. Plants which are too low, or in places overgrown with creepers, soon die. Air and light are the principal conditions for

the welfare of the *Phalaenopsis*. Bees and other insects carry the seeds from tree to tree, and there is a constant vegetation. The period of rest seems to be only a short time after blooming. All plants are strong, the weaker plants seeming to be overgrown by stronger ones.

We will consider now the transferring of the plants from the woods to the greenhouse, the collecting and establishing before the plants come into the hands of the grower. During this period plants suffer greatly. *Phalaenopsis* rarely, or rather never, are troubled by insects or scales in their native habitat, but if a collector does not look after the plants while they are in the hands of the natives the buyer will not get any healthy ones and experience more trouble than the whole business is worth. There are especially two insects from which *Phalaenopsis* suffer terribly; one is a red fly that deposits her eggs in the leaves or the heart, and the other is a scale, which is on the wood to which the *Phalaenopsis* are tied. The presence of the red fly is easily discovered. The leaves look as if punched with fine needles; they get pale, and the whole plant becomes poorer and poorer. Plants infested with these flies should be brought to the light and dipped into hot water every day till all the flies are dead. Scales must be carefully washed off.

Phalaenopsis Sanderiana is often attacked with a trouble when it comes from the woods. The leaves show small holes. It seems as if a butterfly deposits its eggs into the leaves, and after a time a worm comes out. It is the best to cut off all such leaves. The plant does

FIG. 141.—DENDROBIUM DALHOUSIANUM.

not suffer at all as long as there are healthy roots on it. A grower cannot be careful enough in inspecting newly imported plants before they are potted, as it is absolutely necessary to have clean stock, if good results are expected.—(Translated for the "Florists' Exchange" from "Möllers' Deutsche Gärtner-Zeitung.")

Orchids for Beginners.

BEGINNERS in Orchid culture are often at a loss to know what kinds are most suitable to commence with. A succession of bloom throughout the year, as far as practicable, is usually desired, price has also to be considered, and those plants chosen that are easiest to grow. The species and varieties named below will make a very interesting collection.

Oncidium are essentially Orchids for beginners, their only drawback being a somewhat limited range of colour, most of them containing a good deal of yellow. Their long-lasting qualities, however, combined with freedom of flowering, will always secure them a prominent place in collections. *Oncidium crispum*, *flexuosum*, *sphacelatum*, *incurvum*, and *varicosum* of the warm house section, and *O. cucullatum*, *O. concolor*, *O. macranthum*, *O. Marshallianum*, *O. ornithorhynchum*, and *O. tigrinum* of the cooler species will be found a good selection.

Among the *Odontoglossums* it is difficult to know where to stop, as there is hardly a species that may be called difficult to cultivate, and all are beautiful. *O. crispum*, *O. cirrhosum*, *O. luteo-purpureum*, *O. maculatum*, *O. odoratum*, *O. Pescatorei*, *O. Rossi*, and *O. triumphans* are all sterling cool house varieties, and where a slightly higher temperature is maintained *O. citrosum*, *O. grande*, and *O. vexillarium* may be added. *Cattleyas* *Trianae*, *Percivaliana*, *intermedia*, *Mendeli*, *Mossiae*, *Gaskelliana*, *labata autumnalis*, and *Bowringiana* will provide a succession of flowers nearly the whole year through. Among the *Laelias* *anceps*, *purpurata*, *harpophylla*, *Perrini*, and *autumnalis* are all worthy of a place.

When judiciously managed *Dendrobiums* add greatly to the

attractions of the Orchid house in the spring, and *D. aureum*, *D. nobile*, *D. Pierardi*, *D. densiflorum*, *D. thyrsoflorum*, *D. chrysanthum*, *D. Farmeri*, and *D. Wardianum* are only a few of the many good kinds this genus affords. *Cypripediums barbatum*, *insigne*, *venustum*, *superbiens* (fig. 142), and *Sedeni* are easy Orchids to grow, and keep in flower for a long period, the last named species being seldom out of bloom. *Masdevallias Harryana*, *igneae*, *Lindeni*, and *Veitchi* are very bright and effective when in flower. *M. towarensis* is the only white *Masdevallia*, and it may be mentioned here that the bloom spikes of this species ought not to be removed, as they produce flowers several years in succession. *Cymbidium Lowianum*, *Epidendrum vitellinum*, *Lycaste Skinneri*, *Coelogyne cristata*, *Phaius grandifolius*, and *Pleioncs lagenaria* and *maculata* are all useful and popular. *Calanthes Veitchi* and *vestita*, and *Zygopetalum Mackayi* are three good winter-blooming Orchids.

All the species named can be easily wintered in the same house. Sufficient piping should be provided to maintain a minimum of from 45° to 50°. The *Cattleyas* and *Calanthes* ought to have the warmest place, while the *Odontoglossums*, cool *Oncidium*s, and *Masdevallias* may occupy the coolest position. During the summer these latter will, of course, need less heat than the other occupants.—R.

A Disused Quarry in the Engadine.

It was a favourite playground of mine this disused quarry, unattractive enough to mere passers-by, but we wondered what treasures it might hold, and a bush of *Rosa alpina*, gay with such fairy loveliness of palest pink and tender green, tempts us one day to clamber up the stony slope. Above this we see that long grass has grown over the stones, and here we find a plant of *Gentiana lutea* not yet out, also *Epilobium* in great quantities. About 30 feet higher we discover a very fine plant of *Rhaponticum scariosum*, the flower standing 4 feet from the ground, and some of the leaves at the base are 12 inches long and 3 or 4 wide; they are of a dull green colour, and have a silvery lining.

For a closer inspection we scramble over rough stones deceitfully covered with grass, and only just escape trampling upon a beautiful plant of *Thalictrum aquilegifolium*, with its red and golden tassels shimmering in the sunlight. The *Aconitum napellus* is also here, and round the old stump of a tree we find the *Campanula barbata* and a *Centaurea* rich with blue and violet. Scrambling on a little higher the delicious scent of *Daphne striata* meets us; this lovely pink flower is creeping through the grass, its tough little branches adhering firmly to the rough ground.

And now we feast our eyes upon a vision of loveliness. The white *Ranunculus platanifolius*, first attracts us, spreading its slender branches in all directions, giving itself quite an air of importance. Another favourite, the *Arnica montana*, casting a golden glow around it, while the pale yellow *Anemone alpina* is standing sturdily between the stones. Further on, to the south side, we see white Lilies, *Anthericum liliago*, bending their graceful heads, and the *Lilium martagon* in great numbers and of all shades from darkest red to palest pink, even to white, looking as strong as though they were guarding their delicate companions. These nestle more closely round the shelter of a huge boulder, the slabs of which are covered with fine short grass, and contain treasures of most varied colouring. Large tufts of *Dianthus alpinus* adorn each corner of the rock, and *Phyteuma Scheuchzeri* stands out of every available crack, so perfect in beauty with its one pointed leaf close to the flower; while its little grey companion, *Globularia nudicaulis*, softens the surrounding ledges.

When specimens of these are safely in our tins we clamber up, breaking our nails with holding on, and after two or three backward slips we pull ourselves on to a shelf of rock and find we are side by side with the Orange Lily, *Lilium bulbiferum*. This queen of wild flowers must have our attention for a few moments. The quality of its petals, the brilliant colouring and graceful foliage are a study of perfection, and we are filled with intense admiration and wonder as we realise that no human hand has helped it to attain this beauty, but it has grown in God's own garden, and has been nourished and reared by His Almighty care.

Behind us we see *Dracocephalum Ruyschiana*, a very rare plant, and of a dark metallic blue. We also find a specimen of white, and here to our left stands the little mauve Aster, *Erigeron alpinus*, behind which is a plant of *Bupleurum stellatum*. Right before us now we see a carpet of dark blue *Gentiana verna*, and standing out like silver stars on the extreme edge of the rock is *Edelweiss*. This much-coveted flower would satisfy some, and bring their little research to an end; but behind this we alight on to a piece of ground covered with short grass, and here we hope to find some earlier little friends, the snow only having just melted.

The first to appear is the fascinating *Anemone pulsatilla*, looking as though it had not yet left off its little overcoat of feathers. *Gagea lutea* is also here, although nearly over; and large patches of bright

pink *Silene acaulis*; and again of richest blue from *Gentiana acaulis*; then the delicate turquoise of the dwarf *Myosotis*. One more little treasure comes in our path with its softly blended pink and brown, *Geum rivale*. No doubt many other favourites are here, but we are quite content and satisfied with our forty minutes' scramble in a disused quarry.—E. N.

Reminiscences of An Old Florist—No. 8.

I HAVE already described my reminiscences of one of the great events of the sixties, as far as horticulture is concerned, in the opening of the Royal Horticultural Society's gardens in South Kensington, and how it raised expectations which were doomed to bitter disappointment. There was, however, another event, unique in its character and far-reaching in its influence on horticulture, which took place during the same period—I mean the holding of the great International Horticultural Exhibition of 1866. I have attended many horticultural exhibitions, both at home and abroad; but I do not hesitate to say that I have never seen one comparable to this. It was held at South Kensington, and the ground occupied nearly 4 acres, which was covered by a magnificent tent, so as to afford a view unobstructed by any unsightly erection. The laying out of this space had been entrusted to the late Mr. Gibson, the accomplished gardener, who had done so much to raise Battersea Park to the high position that it occupied under his superintendence. Those who frequented the Royal Botanic Society's exhibitions of those days at Regent's Park used always to say that the undulating character of the ground and the terraces of green turf on which the plants were exhibited combined to make a scene of most exquisite beauty. Well! this exhibition was that of Regent's Park multiplied twentyfold.

It was called International, but there were few foreign firms which competed, and nearly the whole weight of the exhibition fell upon the shoulders of our home growers, and well did they sustain it. Of course in my reminiscences I do not expect to enter much into detail, or to draw any contrast between it and the exhibitions of the present. Those were the days when large plants covered with a profusion of flowers were in vogue, and never shall I forget the astonishment of some of our foreign friends when they stood before the magnificent pot Roses of Mr. Charles Turner, or the Pelargoniums of Mr. Charles Turner, or of Mr. Bailey of Shardeloes, and the Azaleas of Mr. Fraser or Mr. Kinghorne. They were undoubtedly marvels of cultural skill, although their artistic excellence might be well questioned. Then, too, was witnessed the dawning of the taste for alpine and herbaceous plants, which has so developed of late years, and of which Messrs. Backhouse & Sons of York were the pioneers.

In looking back upon that exhibition one cannot fail to be struck with the fact that so many who were then foremost on the scene have passed away, and in like manner that many of the flowers are no longer of interest to those who once cultivated them, owing either to the change of fashions or to the improvement in the flowers themselves, the older varieties being superseded by newer ones of better character. Thus, for instance, I remember well a grand specimen in a pot of the Rose Comtesse Cecile de Chabrillant, which was then a great favourite, but which an exhibitor would now be almost afraid to put into a box, even in a front row, on account of its size. The arrangements were all admirable, but there was one thing over which the committee had no power, and which in this variable climate of ours goes a long way, I mean the weather.

Day after day the rain descended, and the guarantors, on whom all the re-responsibilities for the expenses rested, began to feel that their money was likely to be wanted. If, indeed, the exhibition had closed on Saturday night, as was originally intended, there would have been a large deficit; but the late Sir Wentworth Dilke, who was the chairman of the society, invited the exhibitors to meet him, and they agreed to let their exhibits remain until the Thursday following. Owing to this, that which would have been a severe defeat resulted in a complete victory. The weather improved, the price of admission was lowered to one shilling, visitors thronged the grounds, and when the accounts were made up they showed, when all the expenses were paid, a substantial balance in hand: £1000 were given to the Gardeners' Royal Benevolent Institution, and with the balance the Lindley Library was purchased. The only other exhibition holding its place in my memory which was at all comparable to this was one which was held at the opening of the ill-fated Alexandra Park, but it had not the grand features of this unique exhibition.

During the same period I had the opportunity of visiting many of the leading private and professional establishments which had gained for themselves a name by the excellence of their gardens, as well as the more humble establishments where some favourite florist

flower was cultivated. I thus became well known to many in the horticultural world whose acquaintance stood me in good stead when I had more important matters to attend to, and from one and all I received, with rare exceptions, the utmost kindness and consideration. I went down, for instance, to Stapleford to see that ardent and successful florist Richard Headley, who had made his name famous among all Auricula growers by his well known Geo. Lightbody. He was also a very successful Tulip grower, but I remember he had one

many who were associated with me in those days there are few whose memory is more often with me than that of that genial and warm-hearted florist. I went with him as judge to Spalding and other places, and the times we passed together were very pleasant.

I also remember paying a visit to an amateur near Sevenoaks, but whose name I now forget, and saw a beautiful collection of rectified Tulips. I fear that it would be very difficult now in the neighbourhood of London to find such a collection; indeed, the

FIG. 142.—CYPRIPEDIUM SUPERBIENS.

curious notion, which I believe no one accepted but himself, that a portion of his Tulip beds were every year destroyed by some former servant whom he had dismissed.

At this time, too, I ventured to try and revive the taste for florist flowers by establishing the Metropolitan Floral Society; but after one or two attempts I found there was no response at that time sufficient to meet the requirements of such a society. My friend the late Mr. James Cutbush was of valuable assistance to me, especially at one exhibition we held at the Alexandra Palace. Amongst the

collapse of Tulip growing in the South is one of the remarkable things connected with floriculture which has taken place in the last half century. Of course they are very troublesome and expensive; nor do they present a very striking appearance when placed on the exhibition table. The blooms, when fully expanded, look as if they were past their best, and all the paraphernalia connected with them do not contribute much to the appearance of the garden. I was never myself particularly enamoured of the Tulip, though I could appreciate their brilliant and stately beauty when successfully grown.—D., Deal.

Indoor Roses.

PLUNGE Hybrid Perpetuals in pots in a sunny position if they have been thoroughly hardened for turning outside; if not carefully prepare them before placing them out, so that the whole of their foliage can be preserved in good condition. The soil about the roots should be in a thoroughly moist condition when they are plunged, and very little labour will be occasioned in watering afterwards, provided the plunging material is kept moist, and the plants liberally syringed twice a day. Under these conditions they will soon commence in earnest the formation of fresh roots, and a good top growth will result. If this be encouraged it will add strength and vigour to the plants, whereby they thoroughly recruit themselves for the following season. Those potted in autumn in 6 and 7-inch pots, and brought forward in cold frames, may if they have flowered and grown well, be transferred into pots 2 inches larger. These may then be plunged outside. By potting these plants now they will become thoroughly established, and be in the best possible condition for flowering early under glass another season. Those that have not yet bloomed should be kept as cool as possible so that the supply will be continued until blooms are plentiful outside.

No artificial heat will now be needed for the Roses under glass. Abundance of air must be given during the day or the temperature of the house will rise too high and the plants become infested with red spider. A free sturdy growth must be encouraged by syringing the plants liberally and keeping them supplied with water at their roots. Weak stimulants may be given with advantage every alternate time water is needed. With care and good treatment the plants will continue growing and yield for some time a bountiful supply of flowers. Tea Roses in pots that have done duty since last November may be thoroughly hardened and stood outside or plunged; the latter is decidedly the better. Young stock potted in autumn from the open ground, or small plants on their own roots that have been in cold frames up to the present time and are just coming into flower, may occupy the side stages of the greenhouse. As soon as the first blooms are removed from these plants they may be repotted if they are healthy and have done well. Under these conditions they will grow rapidly and make splendid plants by autumn, and can then be allowed to come into bloom to maintain the supply when those outside fail. Not only will they yield useful material for cutting at that dull period of the year, but if pruned moderately hard back will flower profusely again during the months of March and April.

Young plants of Tea Roses rooted this spring may be placed into 6-inch pots and grown from this date under glass. The flower buds

as they appear should be removed, so that the young plants have an opportunity of gaining strength and vigour. These will be also found most useful in autumn, and will continue to flower until Christmas. When ventilation is abundant aphides are perhaps more troublesome than at any other period of the year. The plants must not become infested, or their growth will soon be brought to a standstill. The quickest method of eradicating these pests is to fumigate the house with tobacco smoke directly they make their appearance.—PRACTICE.

Tea Roses in Summer.

HAVING been very successful with Tea Roses last season, a few notes may be acceptable, as my collection comprises many of the best varieties in cultivation. The system carried out was the means of allowing me to cut on an average six dozen good blooms every morning from early in July until about the second week in October. We often hear the remark passed when Tea Roses are not looking or thriving very well that they will not succeed in the soil, or the position is not quite right, when it is only rational attention which is required.

The ground the Tea Roses were planted on was well drained, and the soil worked into good condition by bastard trenching, with the addition of some well-decayed manure. The Roses were planted when the soil was in good order, and a shovelful of turfy loam was placed about the roots of each. The pruning was performed about the middle of April, and the beds were then mulched with some partially decayed manure. When the plants had started into growth, and the shoots had grown about 2 inches, I made it a practice to go over every plant twice a week to disbud the shoots where growing too thickly and destroy aphides. If the least trace of aphides was seen the shoot was dusted with tobacco powder, and once a week until the first blooms appeared they were syringed with soapsuds.

The weather having become dry every plant received 3 gallons of water a fortnight, and the latter part of the season liquid manure. When the first bloom buds appeared, and all through the season, I took off every one which would not be required, as it is very unwise to leave buds that would not be open when the blooms were ready for cutting; and by picking off these useless buds, as it were, extra vigour is thrown into those which are left, and every Rose can be cut with one or two healthy green leaves and a length of stem suitable for any purpose. If any of the flowers were fully open in the morning I cut them rather than let them remain to exhaust the plants and blooms which were to come. By following the above practice the plants grew to a large size, and were continually blooming until stopped by cold nights.—H. A.

Some Good Roses.

AMONG all the classes of Roses there are some which are considered more than usually good, the flowers being models of shape, colour and form. For rich velvety colours, including crimson, red, pink, blush rose, and white, the Hybrid Perpetuals are perhaps the best. That beautiful old Rose Abel Grand produces blooms which are remarkably clean in colour, which is a beautiful, silvery, and glossy rose tint. Alfred Colomb, of a bright, almost fiery red, is one of the best dark Roses. Baroness Rothschild is a delicate pink variety. The flowers are finely formed, and among Roses of the same colour it takes a leading place. Duchess of Edinburgh is another fine light variety similar in colour and build to the variety La France. The latter is now classed as a Hybrid Tea. Camille Bernardin, in addition to its beautiful bright red colour, bordered white, has the quality of sweetness. Dr. Andry and Duke of Edinburgh are exceptionally good dark Roses. The first named is a brilliant red, and very constant, while the latter is usually, when at its best, of a brilliant vermillion. The blooms are of good shape, large, and full.

Etienne Levet is a variety which can present us with fine carmine red blooms of good form and large size. Général Jacqueminot, though an old Rose, is unsurpassed. Large and magnificent blooms of a brilliant scarlet crimson colour are produced. It is useful for all purposes. Horace Vernet is a good reddish purple. Louis Van Houtte is a grand variety of velvety crimson colour. Pierre Notting takes rank as one of the best dark reds, and Prince Camille de Rohan is an intensely dark velvety crimson. In contrast to the last four Madame Clemence Joigneaux, a rosy lilac variety, is excellent, and possesses all the qualities of a good Rose. Marie Baumann is one of the best and most perfectly formed Roses in cultivation; its colour is bright crimson.

Of white Hybrid Perpetual Roses Madame Lacharme, Merveille de Lyon, and Coquette des Branches are the best. The best Noisette-Roses are undoubtedly Maréchal Niel, which is the grandest yellow Rose known; and W. A. Richardson, a beautiful orange yellow colour, almost perfect in beauty and form before opening, but not much good when fully expanded.—E.

The Flower of St. Helena.

Maligned St. Helena.

LOCALITIES, like persons, may suffer defamation for very insufficient reasons, and the island of St. Helena, owing to the fact of its having been selected as a safe place for the deportation of Napoleon Bonaparte, has gained notoriety at the cost of its good name. The posthumously sainted Corsican was in 1815 an object of hatred not only to every nation in Europe, but to all those French people uncorrupted by the gold and pinchbeck glory of his short-lived Empire. When the powers hesitated to shoot him, everyone was interested in getting him safely locked up at such a distance from his partisans, that his diabolical genius for intrigue (which more than equalled his military ability) might operate ineffectively. Here the obese, undersized, and quite undignified "plunger" of monarchs fretted away the remaining six years of his life, bullying his suite, quarrelling with Sir Hudson Lowe, posing as a martyr to the European peoples, and misrepresenting the beautiful island of his residence as a veritable Black Hole of Calcutta.

Hysterical Bonapartist litterateurs have since woven an absurdly heart-rending legend of the Imperial Eagle chained to what they call the pestilential rock of St. Helena. Not to mince phrases, this is all the veriest "buncombe," a foretaste of the methods of our Americanised cheap press of to-day, which strains itself to the bursting point in creating a wave of mendacious sentimentalism. Having thus rehabilitated Bonaparte's memory and blackened the character of St. Helena, the French Chauvinists of sixty years ago succeeded in recovering the ashes of their little Moloch, and ostentatiously deposited them in the Invalides at Paris among the people whom, as Bonaparte sardonically observed in his will, "he loved so well"—i.e., as the epicure loves the oyster.

Its Appearance and Climate.

Had it not been for his policy Bonaparte would, perhaps, have done justice to St. Helena, as he was fond of gardening (*sic*), and might frequently be seen working outside his bungalow in the hills first at The Briars and then at Longwood. St. Helena, like Hong Kong and some West Indian Islands, rises precipitously from the sea much in the same way as some of the western isles of Scotland, and while these fragments of our Empire present none of the aspect of placid tropical luxuriance peculiar to Polynesia, they are far from resembling such cinder-holes as Ascension and Aden. They are, indeed, more like Madeira and the Canaries.

The appearance presented by St. Helena on nearing it is not prepossessing. The fore cliffs tower up from 1000 to 2000 feet barren and sombre in a sort of rampart, except where intersected by savage gorges or glens running down to the sea. Of these the gorge at the mouth of which Jamestown, the capital, lies is the chief, and through it access is obtained to the highlands. There are, roughly speaking, two zones of climate, the one tropic summer (from 68° to 86°), and the other temperate summer (from 56° to 76°). The former prevails at Jamestown, which is "stuffy," but a few minutes serves to transport the visitor to an altitude where flourishes a vegetation not unlike that extending from the Pyrenees to Piedmont. This has nearly all been

introduced during the last 250 years, and from having a rather jejune native flora the island has now come to possess a sort of microcosm of botanical variety.

Bonaparte's Prison.

It is in this upper region surrounded by a moist but temperate summer air, nestling in bold declivities, and approached by roads penetrating some fifty square miles of rocky and romantic scenery that the bungalows stand where the sainted Corsican moped and died of an hereditary disease. For one who had several times rained upon his species the beneficent majesty of a huge prairie fire kind, confinement in such Arcadian surroundings must have proved very tedious, and though horticulture might serve to kill time, it must have seemed tame sport in comparison with Russian retreats and killing men on the scale of Borodino, when at the end of the day 80,000 lay dead or writhing "in one red burial blent." Poor, bored Bonaparte!

In refutation of the Bonapartist slander regarding "the pestilential rock of St. Helena," let us hear what some less prejudiced narrators have to say about it. "When you travel three miles inland you see undulating pastures of the richest green and orange tints, interspersed with woods and Fir plantations, and here and there beautifully wooded glens leading to the sea. The climate is almost perpetual summer. Snug looking country houses lie embosomed in leafy valleys, and trees and flowering shrubs from almost every country grow luxuriantly." And again, "If you stroll out early in the morning you see the path bordered with Roses glistening with dew. Fragrance, light, colour, are everywhere. There are banks of wild Fuchsia in ruddy bloom, great bunches of Heliotrope, with Sweet Briar and Myrtle; vigorous trees of red and white Camellia, in which children are swinging, or overlaiden Peach trees in which they sit eating to their heart's content."

Native Flora.

The native flora of St. Helena when occupied by the Portuguese in 1501 is said to have consisted of some fifty species, twenty-three of which were Ferns, and not a single Grass. There was a belt of some two miles extending round the

island, on which grew only the *Salsola salsa* (Camphire), *Commidendron glutinosum*, and the Prickly Pear (*Opuntia*), but great forests consisting of two species of *Dombeya* extended from this belt to the interior. These, however, have now receded far inland, owing to the action of goats and insects which have been introduced, and can still be noted in course of decay. Among other native plants may be mentioned a *Frankenia*, a *Melissa*, *Erodium sempervivum*, *Commidendron rotundifolium*, *Acalypha rubra*, a *Petrobium*, a *Hedyotis*, two *Nesiotas*, three *Wahlenbergias* and some composite plants called locally "Gum-Wood" and "Cabbage Trees." *Dicksonia arborescens* grows near Diana Peak, and in places the rare *Dombeya erythroxylon*, with its red and white pendent flowers, while in rocky spots the *Phyllica rosmarinifolia* casts a shadow in which no other plant is found to flourish.

Imported Flora.

As regards the imported flora, the list is an astonishing one. It includes all ordinary English vegetables and garden fruits, Peaches

FIG. 143.—ARUM LILIES IN ST. HELENA.

Grapes, Figs, Filberts, Cocoanuts, Dates, Mangoes, Loquats, Custard Apples, and many of the trees, shrubs, and flowers peculiar to Southern France and Piedmont. Conspicuous among the last is the splendid Sage, scarlet Geraniums, and *Richardia æthiopica*. This latter has been taken as the emblematical flower of St. Helena, where, as shown in our illustration (p. 527), it grows in the greatest profusion. The following remarks, kindly sent by Mr. Luckhurst, together with the photograph, will shed further light upon the foregoing description.

"At the Cape, Madeira, and St. Helena the *Calla æthiopica* grows wild literally by the acre, and I well remember when my daughter went to St. Helena, some six years ago, an expression of delight in one of her letters at being able to gather the flowers of this old favourite by the handful. She has also made frequent mention of the marvellous variety of scenery and vegetation in the forty-seven square miles which comprise the area of this small island. Palms, Bananas, and other tropical fruits and flowers flourish in the lowlands, and on the hills there grow Fir trees and Gorse, while wild Strawberries are to be found in their spring, which corresponds to our autumn."

After perusing the evidence, one may safely say that by tamely surrendering to the English people, whom he most hated, Bonaparte escaped his deserts; and that the so-called "prison," to which our so-called "brutal" Government relegated him, was no pestilential rock, and afforded him a more peaceful ending than that to which he condemned at least two million of his fellow men.

Thinning Grapes.

It is difficult to give plain directions about thinning Grapes, for first there is that of the bunches, it being practically impossible to estimate how many bunches individual Vines should carry, as this is determined by their health and constitution. As a rule 1 lb. of Grapes to every foot run of rod, the Vine being on the spur system, is a good crop, and if on the extension mode that weight of crop per half a square yard of trellis occupied by the Vine. In thinning the bunches of free-setting varieties, such as Black Hamburgh, every second bunch on each spur should be removed before the flowers open, and all others which it is desirable to remove as soon as the flowers are set. Those retained will always be the most compact, promising, or well set, and they have the advantage of the entire energies of the Vines. If in addition the berries also are thinned early, there is every prospect, other conditions being favourable, of their attaining full size and finishing well.

The thinning of the berries requires a keen eye to discern what and where to cut, and a quick and steady hand so as not to injure the berries retained. To thin properly the operator should be provided with a small forked stick, about 6 inches long, with which to hold the bunch firmly, and also a pair of Grape scissors. The bunch must be trimmed into proper shape, and then first remove the inside berries, next all the small ones, and then the side berries. The expert will do the preliminary work very expeditiously, cutting off two or more useless berries at a time, and then regulate the remainder to the required distance apart. This will take a practical hand about five minutes per pound of Grapes, calculating the ultimate ripe crop.

A bunch of that weight, or even a 2 lb. one, may not require to have the shoulders tied up, but with larger it is frequently desirable, and so spread out the bunch. Some loop the shoulders up to the trellis with S-shaped pieces of thin wire of the requisite length, while others prop the shoulders from underneath with little pieces of wood. Ordinary cultivators rely on the thinning, the berries being so left that as they swell they lift each other up, and thus compact clusters are secured. The point to be attended to is, to so thin the berries that the bunches when ripe and cut will remain firm and compact, whilst every berry has been allowed room to develop freely to its full size. Thus a well finished bunch of Grapes has the berries compact, yet not so much so as to be wedged out of natural shape.

As regards distance of leaving the berries apart to secure the foregoing result, we have found that the Muscadine and Frontignan varieties should have the berries about three-quarters of an inch apart. Sweetwater Grapes, such as Black Hamburgh, require free thinning at the point of the bunch, and little beyond small berries removed from the shoulders. Indifferent setting varieties, such as Buckland Sweetwater, sometimes only require the small berries taken out; while Foster's Seedling needs free but not overthinning, the berries being oval. Muscats should have the small stoneless berries removed, in the first instance commencing when the properly fertilised are the size of peas, and the ultimate thinning should leave the berries about an inch asunder, as the berries are long and tapering, and do not therefore require such severe thinning as the large round-berried varieties. The vinous Grapes are generally large. Gros Colman ought to have the berries thinned to about 1½ inch apart; Gros Maroc to about an inch at the point of the bunch, but more sparingly at the top. Alicante and Lady Downe's ought to be left about an inch, as they have short footstalks, and do not lengthen out. West's St. Peter's should be left a little closer. Gros Guillaume having large bunches requires to have the berries about an inch asunder, but in compact bunches they must be more severely thinned. Finally, bunches

intended for late keeping should be more freely thinned (leaving few berries in the centre) than those for early use.—G. A.

BEFORE commencing to thin the berries each Vine should have the superfluous branches cut off, so that those retained may be distributed as evenly as possible over the whole surface. This not only adds to the appearance of the house when the fruit approaches maturity, but also enables the Vines to perfect a greater weight of fruit than they are able to do when cropped heavily in some parts and lightly in others. In selecting the bunches it should be borne in mind that it is not always the largest that are the best. Those of good shape, short in the shoulder, with even berries, are preferable to larger examples which have only mere size to recommend them; but if they have the good qualities already defined, the larger they are the better. It is always a difficult matter to determine exactly the weight of crop each Vine will perfect. The health and vigour of Vines must be taken into consideration. Generally 1 lb. of fruit to every foot run of rod is a safe crop to leave on Vines in good condition, but many cultivators leave considerably more, and with the aid of high feeding finish the fruit perfectly.

Medium-sized compact bunches seldom require the shoulders to be tied up, but others of larger proportions are much improved by the practice. Long shoulders will require two or three ties each to keep them in position and prevent the stems from being cut by the weight of the berries as they increase in size. This part of the work being done, thinning the berries should commence. While doing this the bunches may be steadied with a smooth thin stick held in one hand, while the other deftly guides the scissors in cutting out the berries. Commence by thinning those at the base of the bunch freely; two-thirds generally require cutting out; those retained should be as even in size as possible. It will generally be found that the central berry of each small cluster is best, and the only one necessary to leave in the lower part of the bunch. As the operator approaches the top they should be left closer together, as the berries of those varieties with long footstalks force each other upward and outward as they increase in size, and thus fill up the shoulders.

A very frequent mistake made in thinning bunches with long footstalks is to cut out too many berries near the top. When this is done the bunches often look very well while hanging on the Vines, but when cut and placed on the exhibition board or the dessert dish, instead of retaining their form the shoulders spread out in consequence of their want of solidity. The aim of the thinner should be to allow every berry just room to fully develop, and yet form a solid mass when cut. To be able to accomplish this a knowledge of each variety is necessary, as not only do they vary to a great extent in size of berry, but the footstalks also differ in length and stiffness, and they must, therefore, be dealt with accordingly.

Muscat Hamburgh, Muscat of Alexandria, and Mrs. Pince frequently produce many stoneless berries. These should not be thinned quite so early as most other varieties; if left till the berries are about the size of Marrow Peas it is not difficult to see which are likely to swell freely. The small berries should be first cut out, and the others thinned to form compact bunches. If gaps occur in any part the berries around should be left a little closer, and the chances are they will quite fill up the blanks by the time the Grapes are ripe. Black Hamburghs invariably set well, and ought to be thinned freely at the base of the bunch, but scarcely any require removal from the shoulders, except in the case of very compact bunches.

Gros Colman and Gros Maroc both produce very large berries, yet they require different treatment when thinning. The first named has short sturdy footstalks, and the berries are produced freely on the shoulders. Bunches growing on strong Vines not heavily cropped ought to have the berries thinned to 1½ inch apart, in fact this grand Grape requires thinning more freely than any other variety. Gros Maroc requires thinning nearly as much at the point of the bunches, but the top should be sparingly thinned, as it is a frequent occurrence to see this variety with loose shoulders, as the footstalks are long at that part. Foster's Seedling, though not usually producing very large berries, still requires thinning freely, the footstalks being short, and the berries generally very plentiful. Buckland Sweetwater, as a rule, should have less thinning than any Grape I am acquainted with, and rarely requires any but the stoneless berries to be taken out. Large bunches of Gros Guillaume also need little thinning, but much attention ought to be given to tying up all the shoulders, and every cluster containing four or five berries. If treated in this way bunches which appear loose and ungainly develop into grand solid specimens.

Madresfield Court should have nearly all the berries removed from the centre of the bunch, as they rarely have room to develop, and are dangerous if cracking should take place, because they cannot easily be noticed till decay begins. Although the berries of this fine Grape swell to a very large size, those forming the outline of the bunch do not require such severe thinning as many might think, because they are long and tapering rather than great in diameter. Trebbiano often produces very large bunches with loose shoulders. These may be much improved in shape by crossing them at the top, and in some cases coiling them round the footstalk of the bunch. Golden Queen is a good setter, produces very fine berries, and should be thinned freely. Alicante and Lady Downe's ought to be thinned to about an inch apart, as the stems are short and sturdy and do not lengthen out.—D.

NOTES & NOTICES

Recent Weather in London.—The weather has been particularly fine during the past few days, though there has been no return of the intense heat. Monday afternoon was very warm, but each evening was pleasantly cool. On Tuesday the conditions continued unchanged, and Wednesday was showery.

Royal Horticultural Society's Richmond Meeting.—We are requested to state that the committees of the Royal Horticultural Society will meet at 11.30 at Richmond on Wednesday, 27th inst., and members will have to sign their names in the attendance books at the entrance.

Gift of a Park to Blyth.—We are informed that the Home Secretary, Sir Matthew White Ridley, has given a large piece of land to the Blyth District Council to be utilised as a park by the residents of that seaport. The Home Secretary is the lord of the manor, and his generosity is greatly appreciated.

Ousting Foreign Fruit.—The crop of English fruit and vegetables coming to Covent Garden promises to be unusually abundant this year. The quantity of Gooseberries already in the market is so great that the sale prices are lower than they have been for many years. Kent Strawberries have begun to arrive, and on Thursday so many came up from Southampton that prices dropped one-half. The supply will be regular and daily expanding for the next few weeks. The price already reached is so low as to render further importation of the French fruit unprofitable. When the height of the harvest arrives it is anticipated that Strawberries will be obtainable at an unusually low figure.

The Resistance of Seeds to Heat.—Mons. E. Schribaux records in a continental contemporary some surprising results obtained in experiments in killing insects among seeds by the application of heat. Weevils were dead after two minutes' exposure at a temperature of 122° and many other insects at 140°. The indications are that this treatment will also destroy the eggs of insects and the spores of fungi, experiments being now in progress to determine these points. The surprising thing about the experiments is the great resistance to dry heat shown by most seeds. It was found that the cereals, excepting corn, withstood a temperature equal to the boiling point of water, for an hour, without their germinating power being in the least affected. The conclusions drawn are that by short exposures to these high temperatures all animal and vegetable parasites may be destroyed without injury to the seeds. In the treatment of grain for the destruction of smuts, alone, this method would be of exceedingly great benefit to the farmer.

America to the Fore.—The famous Hall of the Massachusetts Horticultural Society, on Tremont Street, Boston, has at last been sold and will be torn down to make room for a modern office building. The Horticultural Society some time ago secured possession of a site on the corner of Huntington and Massachusetts Avenues, opposite the new Music Hall. Its area is 22,500 square feet, and the project to build has only awaited the disposal of the old property. Horticultural Hall was built in 1865. The cornerstone was laid on May 18th of that year. The mayor of the city, members of the city government, members of the Massachusetts Charitable Mechanics' Association, the Society of Natural History, the Massachusetts Historical Society, the Institute of Technology, the Massachusetts Society for the Promotion of Agriculture, and the trustees of Mount Auburn Cemetery were in the distinguished company present. The building was dedicated on September 16th of that year. It is of white granite, and the front contains three statues by Martin Milmore, representing Ceres, Flora, and Pomona. In former days the hall was in great demand for fairs, conventions, and various other kinds of meetings. The site of the hall has long been considered one of the most valuable in the city of Boston, as it has the advantage of fronting on three streets. The last assessment of the property was placed at 565,000 dols. of which the building was 71,500 dols. The society was asking 700,000 dols., but it is understood that a less sum was accepted. The present hall has been a very valuable investment for the society.

Lectures at Chiswick.—In order not to clash with the Richmond Show, Professor Henslow's lecture, announced for Wednesday, June 27th, will be given on Tuesday, June 26th, instead.—W. WILKS, Sec.

Rhododendrons in London.—The annual exhibition of Rhododendrons arranged by Messrs. J. Waterer & Son, Ltd., in the gardens of the Royal Botanic Society, has again been a great success. Visitors to see the gorgeous flowers have been numerous, and a greater amount of interest will doubtless be engendered by those shows. The certificated "Pink Pearl" seemed to attract more attention than any other individual variety.

Gardening Appointments.—Mr. Charles Abbott, late general foreman at Londesborough Park, Market Weighton, Yorkshire, has been appointed head gardener to the Right. Hon. the Earl of Carysfort, Elton Hall, near Peterborough; he entered on his duties on the 7th inst. Mr. Alfred Dryden, formerly head gardener to Mrs. Blacker, of Castle Martin, Newbridge, county Kildare, has been appointed to chief command in the gardens of Sir Gilbert King, Bart., Charlestown, Drumsna, county Leitrim. Mr. W. J. Empson, for the past thirteen years head gardener and steward to the late Mrs. Wingfield, as agent and farm steward to Frank Hargreaves, Esq., Halford Manor, Shipston-on-Stour, Warwickshire. All communications after June 23rd should be addressed to Merton Grange, Gamlingay, Cambs.

Where Our Oranges Come From.—Few people are aware that we import many millions of Oranges from foreign centres each year. The largest quantities reach our markets from Spain. The imports from this country, according to the latest Government returns, exceed 6,216,000 bushels. Spain is the greatest Orange-exporting country in the world. Italy stands second, Turkey comes next, then Portugal, and then the Azores. Egypt sends us more Oranges than France, and the United States has 22,313 bushels to her account, these fruits coming from California, and consisting of the famous seedless variety. A few Oranges come from Brazil and Germany. We get few Oranges from our colonies at present, though in future years the imports will increase considerably.

A Note on Perfumes.—The South of France and Italy supply the majority of flowers from which perfumes are extracted. English flowers, for the most part, lack the intensity of odour necessary for this purpose. Our little island is, however, unsurpassed in its production of Lavender, the moist soil being admirably adapted to its growth. The perfume of Lavender is old-fashioned, but sweet and wholesome, indeed the Queen prefers it to all others. A flower's perfume is not as a rule stored up in a gland that can be easily removed. It is, says a contemporary, a breath or exhalation that is given off while the flower lives, and ceases at its death. Perfume may be stolen from flowers in the following way:—Take two plates exactly alike in shape and size; cover the inside of them with fresh unsalted butter; strew one plate with fresh, sweet-smelling flowers, and cover it tightly with the other. At the end of twenty-four hours the butter will be fragrant with the perfume given off by the flowers.

Phylloxera in Spanish Vineyards.—The spread of the phylloxera in the sherry district of Spain appears to be a serious matter. In most of the Jerez vineyards its ravages have been of quite recent date, but they have been extraordinarily severe. For example, while in 1898 in ten different areas only forty Vines were recorded as attacked, the return of the same areas for last season stated 4000 to have been destroyed. In a well-known Jerez vineyard carrying 48,000 Vines the phylloxera made its first appearance in 1897. Until then the yield of the estate had been from 100 to 140 butts per annum; but in 1898 only fifty-six butts were made, and last season the yield sank to six butts, or one-twentieth of the normal. The only remedy found to be of the slightest avail is entire replanting with the American Vine, and grafting on to it the Sherry Grape. The process is a very expensive one, but many proprietors, seeing the excellent results obtained, have lately been induced to adopt it. In order to assist them as much as possible the Government have taken off the heavy duty on vineyards in the case of all those attacked by phylloxera, and have furthermore, says a weekly contemporary, granted ten years' freedom from taxation for all those which have been replanted with the American stocks. This wise action should enable sherry growers to tide over their difficulties. Meanwhile, it is satisfactory to learn that, though the vintage of 1899 is much reduced in quantity, it is said to be, on the whole, of fair quality.

A Novel Exhibition.—A three days' exhibition of artificial flowers is to be held at Kingston in July, under the patronage of the Mayor (Alderman Moatt). The flowers will be made and sold during the exhibition by cripple girls and members of the Watercress and Flower Girls' Mission.

New Bye-Laws of the Royal Horticultural Society.—These, amounting to ninety-six in number, have already been distributed to the members in pamphlet form. The Rev. W. Wilks, the secretary, now desires us to intimate that a special meeting will be held on Tuesday, July 3rd at 4 o'clock in the afternoon at the Drill Hall, Westminster, for the purpose of considering them.

Bradford Horticultural Society.—The schedule of the Bradford Horticultural Society, which has recently come to hand from the honorary secretary, Mr. W. D. B. Pearson, Peel Park Hotel, Bradford, embodies about nine dozen classes. Amongst these prizes are offered for all sections of the gardening community, and a really excellent exhibition should reward the committee's efforts. The show will be held in the Drill Hall, Otley Road, Bradford, on Friday and Saturday, August 24th and 25th, and full particulars may be had from Mr. Pearson, at the address given above.

The Royal Horticultural Society.—What may well be described as practical evidence of the great popularity of the Royal Horticultural Society was evidenced at the Drill Hall on Tuesday, 5th inst., by the fact that the record number of 116 new Fellows were elected. It does not look as if these were frightened because of the council's proposals with respect to the new and the old Chiswick. Last year the total number of new Fellows was 653. I should think that a considerable approximation to that number has already been made this season. This fact serves to show that the society is a strong constituency, and is far from being a close preserve.—A. D.

Royal Agricultural Benevolent Institution.—At the annual meeting of this society, which was held on Wednesday, 12th inst., Mr. W. B. Parsons presided over a good attendance. In its report the council pointed out that they had 1180 persons on the books of the society, which, with the sixty-five elected on the occasion under notice, involved the expenditure of upwards of £26,000. The income for the year ended December 31st, 1899, amounted to £21,746 3s. 8d. During the past forty years the institution has benefited 3153 persons at a cost of £415,413. The council makes a strong appeal for further support. The secretary is Mr. C. B. Shaw, 26, Charles Street, St. James'.

The Gardeners' Company.—Mr. Philip Crowley, F.L.S., Master of the Worshipful Company of Gardeners, entertained the Lord Mayor and Sheriff's and other guests at dinner on Thursday night at the Prince's Restaurant, Piccadilly. After the loyal toasts had been honoured, "The Worshipful Company of Gardeners, Root and Branch," was proposed by the Lord Mayor, and responded to by the Master, who stated that though the company had existed as a guild or mystery from very early times, and used to hold a market near St. Paul's, it was not incorporated until the reign of James I. For some time it had fallen into low estate, but had recently revived, and was now, in conjunction with the Royal Horticultural Society, doing its best to promote the art and science of the gardeners' craft. The company then adjourned to the galleries of the Royal Institute of Painters in Water Colours, where the master held a reception, which was attended by a large number of representatives of the City companies and friends of horticulture. The floral adornments were a noteworthy feature of the occasion.

Fulham's Riverside Park.—On Saturday a charming extension to the pretty Bishop's Park at Fulham was thrown open by the local vestry. Mr. Oscar Drew performed the ceremony. Upon this spot originally stood a residence known as Pryor's Bank, at one time occupied by Walsh Porter, who, it is said, on several occasions there entertained George IV. whilst Prince of Wales. On the site of the house now stands an imposing pavilion, the interior of which contains well furnished reading and refreshment rooms and offices. The grounds are artistically laid out with shrubs and flowers. Mr. Drew, in his address on Saturday, said that in a large measure the beauty and completeness of the space were due to the London County Council, who had rendered valuable assistance, financial and otherwise. He regarded the spot as a delightful one, situated as it was between the Bishop's palace and Father Thames, and considered that the commanding promenade which had been built on the river wall completed an ideal riverside park.

Protection of Wild Birds.—At the recent meeting of the British Ornithologists' Union it was unanimously agreed "that any member of the British Ornithologists' Union, directly or indirectly responsible for the destruction of nests, eggs, young or parent birds of any of the species mentioned in a schedule, should be visited with the severest censure of the Union." This is the first authoritative expression of opinion on the subject from the most eminent body of experts in Great Britain, and will be most welcome to all who have unceasingly laboured to protect our birds from extermination.

The Weather.—"A. D." describes the weather of the 1st of June as "cold, wild, wet, and wretched," how does he describe the 12th? There is between the two dates a difference in temperature of 24°, the 1st being 62°, the 12th 86° in the open. Such a range of temperature in so short an interval of time is phenomenal, especially before midsummer. While, too, in some parts reports come of flooded streets and roads on the 12th, our rainfall for the same day stands at the lowest fraction—namely, 0.01. There is reason for much thankfulness for this extreme even when one reads of such deluges, and lightning and hail damages wrought in other places. Such high day temperatures without rain have been most trying to the progress of summer bedding and other planting.—S., Wilts.

Devastation by a Hailstorm.—Birmingham and some of its suburbs were visited on the afternoon of the 12th inst. by very heavy thunderstorms, and more particularly at Knowle, a village about ten miles south of the Great Western Railway. The storm of hail was there of unprecedented volume and destructiveness, and some idea of its effect may be formed when it is stated that the roofs of several greenhouses were completely demolished, and the Potato plants and tubers in two market gardens were in some instances completely uprooted by the force of the wind, rain, and hail. Cabbages, Lettuces, Strawberries, Gooseberries, and flowers were shattered, also the Apple and other fruit trees more or less decimated of foliage and fruit, whilst in places, it will hardly be believed, that the pieces of hail lay from 12 inches to 18 inches deep.—W. G.

Daily Forecasts of Weather During Harvest.—During the harvest season the Meteorological Council will supply by telegraph daily forecasts of weather to all persons desirous of receiving them upon payment of the cost of the telegrams, 6d. daily, for the period during which the forecasts are supplied. When it is so requested the charge for portage (if any) will be arranged for by the Meteorological Office, an equivalent amount being added to the charge for the telegrams. The special harvest forecast is prepared at 3.30 P.M. each day, and is applicable to the twenty-four hours from midnight following the time of issue. Applications for these forecasts, stating the period for which they should be supplied and particulars as to the shortest telegraph address and portage, should be sent to the Secretary, Meteorological Office, 63, Victoria Street, London, S.W., from whom all particulars respecting the supply of weather information may be obtained.

The first part of the week was remarkable for very high temperature, the highest being on Monday, the 11th inst., when the shade temperature outside the screen read 90.50°. There was a slight thunderstorm on the 12th inst., since which time the weather has been more or less dull.

The Royal Horticultural Society.

THE census of opinion proposed to be obtained from the Fellows of the society by your correspondent, "Hear Both Sides," may be useful in enabling every Fellow in the society to express his or her opinion, but 70 per cent. of them at least know absolutely nothing or care nothing about the matter under discussion. Certainly the council can furnish to every Fellow such information in print before inviting a census, as shall fully detail all the pros and cons of the subject, and especially in relation, first to the horticultural uses or value of a show or meeting hall on the one hand, and of a larger and better placed garden on the other, with full information as to site and cost.

To invite any opinion on the matter referred to would now be useless, simply from lack of information. I have great confidence in the intentions, business capacities, and horticultural earnestness of each of the members of the council. But all the same they seem now in danger of allowing a policy of drift to prevail, which may in the end result less in wrecking any one proposal than in wrecking the society. What everyone so much wishes is that the council should take the Fellows entirely and absolutely into its confidence, and that speedily.

The important matter under consideration should be settled before the holiday season commences. At present nearly all discussion is taking place in the dark. How much that fact is evidenced is shown in your last week's correspondent's reference to the annual cost of a garden at Limsfield as £3000. When he says "estimated cost," I must ask, Whose estimate? Is it that of some one who knows, or of someone who does not know? Will not the council take a very early opportunity to enlighten the Fellows as to all the facts, then some practical decision may be arrived at that should settle the matter finally?—A FELLOW.

The Small Apple Election.

I MUST say I am deeply grieved to find that the interests of science should have suffered for the sake of a penny stamp. Alas! it is worse than the old story of spoiling the ship for a halfpenny worth of tar; but I am even sorrier to learn that "A. D." should think me discourteous. I can now only apologise for my neglect, and promise that if ever in the future I do venture to ask his valued opinion upon any subject I will not omit the postage stamp. May I ask that you will kindly allow me to make an apology to the rest of my correspondents before dismissing this weighty matter?

In reply to the remainder of "A. D.'s" remarks, I must say that I rather fail to catch the point. I think that the opinion of, say, fifty selected men, who live all over the country, and who most of them get their living by selling either fruit or trees (some both), is as valuable, and possibly more valuable than the opinion of 200. Again, although I admit the power of the Press, I am not sure that a larger proportion of the persons whose opinion I invited would have given themselves the trouble to make copy for a gardening paper, than those thirty-two who kindly replied to my inquiries. I can at any rate assure your readers that the signatures appended to the answers sent in are such as would carry weight with them were they published. I may add that several of the twenty-four referred to have since written, saying that they were prevented from one cause or another from writing.

Now, Mr. "A. D.," I have at any rate set the ball rolling, and the field is open for you to enter and show how the work can be done better. I am only a beginner, and mistakes are excusable with tyros, but I hope to see you do something far superior. If you return the compliment of asking my opinion I can assure you that you shall have it if I am in the land of the living; it is not contained in the last election.

If this little election has done no other good, it may help to show that there are two sides to the question of planting all early Apples to clear off "before the Americans come in;" I know the salesmen advocate this course because they like to be "off with the old love before they are on with the new," and I also know that many growers in the south share in the opinion that to plant all early Apples pays best; but do not run away with the idea that everyone thinks so, Mr. "Gleaner," the answers of my correspondents clearly show this, and my own experience would endorse their opinion. May I say that for twenty years I managed, and sold the produce from, 100 acres of Apple orchards, so I have been through the mill, and my experience was that, taking an average of seasons, the very early and very late Apples paid best. I fear I have only replied very briefly to "Gleaner's" kindly criticisms, but I am just off for my holidays, and when I return, reinvigorated as I hope, I trust I may find that abler pens have taken this subject in hand.—A. H. PEARSON, *Lowham, Notts.*

Tropæolum speciosum.

I NOTICE on page 500 of the Journal that "Ret Rail" mentions *Tropæolum speciosum* as a South American plant. Now South America has three *Tropæolums* of its own—the tricolor, commonly called the soldier; the pale blue, the shade of a wild Violet; and a yellow something, the same, but not exactly, as *canariensis*. This "speciosum" came—I was told years ago—from the Himalayas, brought thence by a member of the Hamilton family to the Isle of Arran, where it flourished so wonderfully, receiving the moisture to which it was accustomed in its mountain home. Then it was introduced to the mainland of Scotland, and was gradually brought south. Mrs. Earle writes of it also as from South America, which I am convinced it never saw. I grow mine on a south wall, also in other aspects in Cheshire, and cannot eradicate it. I also know of gardens near where it is a weed rising in most unexpected places, but then it gets moisture at the roots. It must be shaded by "Geraniums" or anything else being planted over it, so as to keep the roots cool and moist. This is the one thing necessary, as in watering the "Geraniums" the *Tropæolums* also get watered.—MRS. H. F. F.

Are Young Potatoes Dangerous Food?

My attention was drawn to this matter recently by hearing of a gardener's family suffering serious stomacheal derangements and poisoning symptoms, with considerable irritation, that could not be attributed to any cause except from using prematurely young or "new" Potatoes. It would be of the greatest interest if you, or some of your correspondents who have fully considered the matter, would say at what stage are new Potatoes safe dinner food. I am aware the seasons affect the result. Probably all outdoor crops, including fruit, are at least a fortnight late this year. There will possibly be a 20 per cent. absence of sunshine at the end of June for that month alone, and this materially affects the ripening and maturity of early Potatoes, and hence their quality as food products. Do Potatoes and all solanaceous plants contain poisonous ingredients, and is this greater or less in their earlier stages? Do they become eliminated with age, or ripening, or in boiling or steaming? I need hardly point out of what world-wide interest this subject is, and how very deserving of serious study, more especially in a season like the present, when the Potato crop is likely to be used before being fully ripened or matured—not merely as a farm crop, but in the garden as well. In the south of Ireland this is an unusually moist and humid month of June so far.—W. J. MURPHY, *Clonmel.*

A Dearth of Peaches.

To many readers of the *Journal of Horticulture*, no doubt, such a title as that chosen by "H. D." (page 476) would scarcely be understood, at any rate among private gardeners. There are those whose business it is to dispose of surplus Peaches in the season of plenty to whom the notes in question might appear strange reading. "H. D.," however, mentions that more particularly is this dearth felt in the North and Midlands. I do not think the West of England knows of such straits in the Peach season, and prices such as are noted would be gladly welcomed. Covent Garden salesmen monopolise a considerable quantity of English-grown Peaches, and those who produce fine fruit in sufficient quantities to make a connection with a good house obtain satisfactory prices. It is the small growers who dispose of their produce locally who suffer in the prices obtained, while the market growers, from the fact of their supply being greater and longer lasting, obtain better value.

At least one, if not more, of the leading London salesmen adopt a course which is commendable, and that is to send orders to the producer for fruit to be transmitted direct to the consumer. This, when the packing can be depended on, is much more satisfactory for both, because the fruit in its direct despatch can be saved miles of railway journeying. There must, of course, be confidence assured between salesman and grower to allow of this course working satisfactorily. From outdoors in the south there will be quantities of Peaches from open walls, the prospects generally being very promising. Salesmen in the North having a difficulty in securing satisfactory supplies ought to communicate early in the season with growers in the South and West, when their troubles would probably cease.

With suitable houses and careful cultivation pot trees are no doubt, as "H. D." says, the most economical, and it is really marvellous the crop that can be obtained from them. For this phase of Peach culture there must be an adequate supply of water and labour, for they need frequent attention in bright weather. Under such conditions the earlier, as well as a portion of the main crop, can be grown in pots, but without doubt the grower whose aim is to secure fancy prices for his fruit must resort to permanently planted trees, as from these only can extra sized Peaches be gathered.

It is surprising to see how Peach crops vary in different gardens even when all receive the best attention. There is no denying that outdoor-grown Peaches possess very high quality, and in soil suited to them they are not of much trouble as regards their roots. There are

of course, obstacles that the outdoor crop meet that are practically unknown under glass. Wasps, hornets, and flies in some seasons destroy a great proportion of the crop, and they are so persistent that it is with difficulty their raids can be suppressed. Woodlice give trouble where nailing of the branches is resorted to, and the walls are perforated with holes. Then there is the danger of spring frost, which sometimes does irreparable damage. It was proved last year that the Peach flower can endure much cold, as when it appeared that flowers were ruined by sharp frosts, really good crops were produced. Fortunately the flowering season passed without any damage being inflicted this year, and no blister appeared despite the cold and trying spring.—W. S.

Notes on Melons.

IN most establishments there will be Melons in various stages, and a few remarks on them will probably be useful. Plants with the fruit ripening must have a plentiful supply of air, and water should be withheld from the fruit. If the plants are strong and there is a disposition to crack, cut the growths carrying them half through a few inches below the fruit. A dry atmosphere is essential, and a temperature of 70° to 75° artificially, falling about 5° at night. If the sun be powerful place a slight shade of some kind directly over the fruit. Water need only be given to prevent flagging, and a light protection from bright sun after a dull period is a much better way of preventing flagging than heavy waterings and a close vitiated atmosphere.

In the case of plants swelling their fruit, those recently set should have more soil added to the ridges or hillocks. Let it be warm, moderately heavy, rather moist, and press it firmly. Give a thorough watering when the fruit is the size of an egg, and follow in the course of a day or two with liquid manure, then mulch with sweetened horse droppings. Water will be required about twice a week, or only once in dull weather, but this is governed by the borders to a great extent. Remove all fruit but three or four on a plant, also blossoms, and afford the needful support. Stop or remove laterals, not allowing secondary growths to interfere with the principal leaves. Syringe twice daily—in the afternoon not later than four o'clock, having the foliage fairly dry before night, and sprinkle the floor about five or six o'clock with weak liquid manure, and give a little ventilation at the top of the house the last thing at night. This will save trouble if air is not given early in the morning. On bright mornings commence ventilating about seven o'clock, or at 75°, and increase it with the advancing sun. Close at 80° to 85°, increasing to 90°, 95°, or more. Fire heat will only be necessary on cold nights and in dull weather.

Plants setting their fruit should have the foliage disposed thinly, so that air and light may have free access. The growths will then be stout and short jointed, the foliage thick in texture, and the blossom will be proportionately strong. Ventilate constantly, and, if dull, have a little warmth in the pipes to insure a circulation of air, and when the heat falls below 65° at night or 70° to 75° in the daytime. The soil must be sufficiently moist to prevent the leaves flagging, and only moderate moisture will be required in the atmosphere. To prevent the deposition of moisture on the flowers, maintain a warm buoyant atmosphere. Fertilise the blossoms about noon on fine days, and when several are expanded on a plant, stop at one joint beyond the fruit, to ensure uniformity of swelling.

Young plants for trellises should be trained with one shoot, and laterals rubbed off up to the first wire, and then every alternate lateral on opposite sides, stopping the leading shoots when about two-thirds up the trellis. Flowers ought to show on the laterals; if they do not do so at the second joint stop at that. Plants for training over the bed should be stopped at the second leaf. Select four of the resultant shoots, training two to the back and two to the front of the frame or pit; remove all others carefully. If only two shoots result stop them at the second or third leaf, and make a selection of the best resulting growths for training. Keep the stem clear of laterals and leaves for a space of about 6 inches from the collar. Remove every alternate lateral on the shoots, stopping the leaders when from 12 to 15 inches from the sides of the frame. Let there be no deficiency of moisture at the roots, and add fresh soil to the ridges or hillocks as the roots protrude. Syringe at closing time, but avoid wetting the collar, as it may lead to canker. Provide the necessary ventilation for insuring sturdy short-jointed growth. Put out plants as pits and frames become vacant, and if a gentle warmth at the roots be afforded it will give the plants a start and be all that is necessary. Close early and keep the growth well regulated not less frequently than once a week. Shade only to prevent flagging.

A last sowing of seeds for late fruit should be made at once for planting in manure-heated pits and frames. Plants from this sowing will afford fruit at the latter part of September, and be useful if properly attended to. Growers with command of light well heated structures may continue making sowings as required until the end of July. The plants from the last-named sowing will continue the supply up to the beginning of November, after which the fruit is generally of moderate quality.—GROWER.

Wistow Hall.

SCATTERED throughout the Midlands are many ancient castles, abbeys, and mansions, around which cluster historical memories of those turbulent times when continuous internecine strife sapped the vigour of the nation, and delayed commercial expansion till juster laws and a better form of government prevailed. In Wistow Hall there is still a famous relic of those far-off days, and the mansion has the distinction of having twice sheltered a king. Charles I. slept there on the night preceding the battle of Naseby, and on resting there after the battle was compelled to beat a hasty retreat. The king's attendants in their hurry placed the wrong saddle on his charger, with the result that the saddle and trappings used by his Majesty at the famous battle are still preserved in a glass case at Wistow Hall. This relic was greatly prized by the Halford family, whose ancestors held the estate before King Charles' period, the first baronet being created by Charles I. The estate is now in the hands of Mark Firth, Esq., who, together with Mrs. Firth, take great interest in gardening, and are continually making improvements in the fine, old—but previously neglected gardens—which surround their pleasant home.

Two Horticultural Cyclists.

On a fickle April day two Leicester horticulturists resolved to leave for a time the bustle of that thriving Midland town, whence boots and hosiery find their way to every quarter of the globe. Astride those wonderful inventions of modern times the two pressed through the busy haunts of toilers into the sweet fresh country air, where verdant fields, and hedges in their pristine beauty, formed a gladsome picture of England's charms in the days of spring. "No need to hurry on such a day as this," remarked No. 2—who, to tell the truth, was not in "training"—and was therefore sometimes content to let the "leader" go, and quietly follow at a pace more suitable for thoroughly enjoying the pleasant scenes. Thus eight miles were in due time traversed, when a sharp turn in the road and a steep descent brought us to the entrance of the park. A glimpse of the white walls of the Hall are quickly seen in the distance, the tower of a pretty church appears on the opposite side, and then the gardens are reached, where we received a hearty welcome from Mr. F. J. Clark, the head gardener, whose acquaintance was previously made at one of those institutions where so many gardeners meet—viz., a Chrysanthemum show.

An Odd Corner.

On our way to the kitchen garden we passed through an enclosure of a type so often met with in old gardens, a kind of odd corner, apparently designed to show an outline as irregular as possible, neither circular, square, nor oblong, but a curious combination of arcs and angles. New walks have recently been made here, worthless plants uprooted, and good borders formed for herbaceous plants, one of them, having a west aspect, being entirely devoted to the choicer kinds of hardy Liliums. I venture to predict that this border will in its season prove a very great attraction, as Liliums certainly rank among the most beautiful and showy flowers we have. When the borders are well made, and sound bulbs obtained, they will go on for years increasing in strength, and forming fine large clumps. All gardens should have a large bed or border of Liliums.

The Vegetable Garden.

The kitchen garden is a fine one, being bounded on three sides by high walls, and on the south side by a low fence, which arrangement renders the whole space open and sunny. In this department, renovation, improvements, and thorough culture are evidently being carried out just as opportunities allow. Many old fruit trees with gnarled and cankered branches, which were only cumberers of the ground, have been uprooted, to be replaced by young ones, arranged in a regular fruit quarter, instead of on the ancient plan of dotting them like sentinels in various parts of the garden. The fame of the Wistow vegetables had already reached my ears, the Lettuces, Cauliflowers, Onions, Leeks, and Celery, each in their season having been described to me as giants among the pigmies with which they came in competition. I, therefore, naturally was on the look out for the cause of such success. It is the old story of laying a good foundation by means of that deep and thorough culture which the British gardener can never afford to neglect. By degrees, the whole of the garden is being trenched three spits deep, and manure is used with no unsparing hand. The gardener who does this fears not the drought of summer. Mr. Clark has learned gardening

in a good school, for he is an old pupil of Mr. E. Beckett of Aldenham House, and has carried into the heart of the Midlands those splendid cultural practices which have made Lord Aldenham's gardens famous in the horticultural world. In a season like the present there is not much in the way of vegetables to be seen at so early a date, but the young crops were advancing as fast as the cutting winds and frosty nights would allow them to do. New beds of Asparagus had, however, been formed, and these promised to give good results in due time.

The Vineries.

In the adjoining vineries I noticed an admirable illustration of the "old" and the "new" methods of culture at Wistow. The old Vines were struggling for existence, the wood being weak, the bunches few and puny. The next compartment, however, revealed an achievement highly satisfactory. Young Vines (principally Muscats) were planted last year, when they almost reached the top of the very long rafters,

and tender looking. Great use has to be made of pits, frames, and hotbeds for raising plants and early vegetables, and another good range of houses would be a great boon and largely increase the capacity of the gardens for fruit and vegetable production. A word must be said about the Chrysanthemums, of which Mr. Clark is a successful exhibitor. They are strong, sturdy, and in every way promising in appearance.

The Conservatory.

From the plant stove we crossed the green sward, noting by the way a walk bordered on either side by splendid Rose bushes, with rustic poles fixed at intervals for climbers; onward we passed by newly made Rhododendron beds to the large oblong shaped conservatory adjoining the mansion. This was indeed a picture of brilliant beauty, the front stage being occupied by Azaleas, Deutzias, Spiræas, double Wallflowers, Genistas, Cinerarias, and Liliums. Fine Palms formed the background, among which were interspersed grand plants of Lilium

FIG. 144.—WISTOW HALL.

the canes being exceptionally strong and short-jointed. They were shortened to almost half their length, had broken regularly, and were each carrying several fine bunches. In due time they will, I am sure, produce Grapes of the highest quality, as the rods are fully 5 feet apart, and to grow Muscats to perfection they must have plenty of space. On the back wall grand blooms of Maréchal Niel Roses were hanging on strong trees in pots, and a good crop of that fine Tomato Eclipse was advancing, on plants grown in pots under the Vines.

The Plant Houses.

I noticed examples of that attractive yellow flowered plant *Celsia cretica*; when grown under glass Mr. Clark finds it of great service for decorative purposes, though in the South of England it is quite hardy. A fine stock of bedding plants, of which large numbers are required, was coming on rapidly. In the plant stove, Palms, well coloured Crotons, and Dracænas of a useful size were evidence of cultural skill. For lack of other suitable space a few Cucumbers were also grown in this structure, and grown well, too, for the fruits were long, straight,

Harrisi, some stems carrying eight or nine flowers, the whole of the plants looking pictures of health. It seemed to me that No. 1 looked on them with envious eyes.

The Flower Garden.

The pen has run on, and there remains little space to treat of one of the great features of the place, the fine compact geometrical flower garden, situated immediately in front of the conservatory and mansion. There indeed was a blaze of colour of which we caught glimpses when on the higher ground previously traversed. Tulips, Hyacinths, Pansies, Alyssum saxatile, Wallflowers, and Daisies were the principal plants employed to create so grand a display. Yellow Tulips with a groundwork of purple Pansies, scarlet and white Tulips intermixed, red Tulips, with a groundwork of white Pansies near masses of purple Hyacinths, were some striking combinations noticed, and Wallflowers played no small share in contributing brightness to the scene as well perfuming the air. These flower beds are situated in a slight hollow, and their full beauty is best seen from some of the higher windows of

the mansion, where the eye looks down upon them, and can take in the whole at a glance. From the bright flower beds the rising ground of verdant grass leads to an irregular belt of trees in the woodland beyond, and the whole thus forms a lovely picture which lingers in the memory.

The Ancient Yews.

Still one other feature had to be noted before Wistow was left behind. We traversed a woodland walk bordered with gay Daffodils, and the sky blue *Scilla sibirica*, and pressed onward in a quiet retreat till we reached some ancient Yews, famous by reason of their gnarled and twisted trunks, which must have withstood the storms of many centuries, and, like the England in which they stand, still show no signs of senile decay. It is always a pleasure to visit an establishment when the relationship between employer and employed are of that happy description which enables the one to carry out with pleasure the wishes of the other, as at Wistow.

To Mr. and Mrs. Clark for their kind hospitality the thanks of Nos. 1 and 2 are due. We were glad to get out of Leicester during the freshness of morning, but welcomed its lights at night as wayworn travellers in a driving rain.—H. D.

The Charm of England.

LONDON at last! We get our luggage together. It is nine o'clock on Saturday night, and we wonder what we are to do with our things and where we are to go. A Queensland squatter who has been used to the back blocks, and has about 100 square miles of country on which he lives, wears an expression of hopeless perplexity, and exclaims almost tearfully, "I've been about five minutes in London, and I'm satisfied it's too big a place for me. I'm off. I'll take a cab and drive into the country." He darts toward a hackney coach, but suddenly stops, as if turned to stone, and stares intently at the cab. Then he exclaims, "Look at it! No. 17,240. Fancy, seventeen thousand cabs. Oh, why did I leave my little —" But here, says the writer in the "Daily Express," his friends arrived and took charge of him.

With Monday morning came our first good look at the city of the world. Companions for seven weeks journeying across the world, our patriotic little party had to break up. Each had to go his own way, and I was left in the town alone. Lonely. I had heard people say how lonely one could be in London. But now I know. The countless throngs of people, the endless streets, the network of traffic, the rush of business, bewilders all the faculties and makes one stand dismayed. "What am I among all these millions? Why, if I dropped dead no one would ever know anything about me." That was the feeling—a feeling that grew hour after hour as I continued to discover myself in new districts, utterly unable to realise how I got there, and only getting out of one puzzle to get into a worse one. I spent all the morning trying to find the Strand. I spent all the afternoon trying to lose it. I had made up my mind that I would find my way back without taking a cab—but I made a shameful surrender, drove home and forfeited my self-respect. Through the night the spectre of the City was upon me. Bewildering crowds passed before my heated brain, and I tried to solve impossible problems. If there are six million people in this City, and they take on the average twenty steps a minute, how many footsteps have fallen in London to-day? How many pulse-beats have there been in London to-day? Alternately I tried to realise the greatness of London and to forget it. I could do neither. A fear—an unreasoning fear, but a great fear—fell upon me.

With the first streak of dawn I arose, gathered up my belongings, and fled. I told the cabman to drive to the railway station. "What railway station?" he asked. "Any one," said I. He drove me to some station. A train was going somewhere. I think it was in the direction of the Isle of Wight. I bought a ticket and got in. Presently we sped away, past the Thames Embankment, past Westminster, away from the nightmare of streets, and shops, and houses, and 'buses, and endless throngs in which was not one face I knew. At the village of H—I left the train. There are green fields here, and running streams, and flowers, and singing birds, and giant trees, and gentle breezes whispering through their branches. It is springtime, and the merry month of May, and the blossom is on the tree, and the glory of God is upon the land. I wander down leafy laues and lie by the babbling brook, and the air is sweet to breathe, and the peace of the great All-Father is in my heart.

Ah! this is England; this is the Motherland which, enshrined in song and story, has struck her roots deep in the hearts of millions in distant lands who, though of English blood, have never seen England. Not London, whose greatness drives away the novice in an unknown terror, but countryside and river, and lake and village, and wood that take the wanderer to their hearts, and seem to whisper, "Rest; here is peace." This is the England I came to see; the England that has

made the breed of men who overrun the world. Twenty miles away is London—vast, inconceivable. They say that there men win world-wide fame, imperial power, fabulous wealth. It may be so. Here peace comes to us, and—hear that blackbird singing.

Hardy Azaleas.

THE value of *Rhododendrons* is familiar to all, but it seems that the merits of hardy Azaleas are not fully recognised by those engaged in the formation or planting of new gardens. They yield their flowers in the greatest profusion, the colours are most varied and rich, and a large proportion of the varieties possess a peculiarly powerful yet agreeable fragrance. Many of those that flower before the leaves are fully out become masses of the richest yellow, orange, red, and rose-shaded flowers, the brilliant effect of which can scarcely be realised by those who have not seen a number of plants together.

Somewhat sheltered positions suit these Azaleas best, chiefly because their flowers are soon damaged by wind in exposed places. Similarly they do not thrive in very dry soil, for most of them are derived from the swamp-frequenting North American species, and even those that are not found in such wet localities are chiefly confined to woods where they enjoy considerable moisture and protection. The soil must be well drained, and though a compost of peat and loam is generally employed the former is not essential, as tufty loam not too heavy with a good proportion of leaf soil will make excellent beds for them. The hardy Azaleas cultivated in English gardens have originated from the Mediterranean *A. pontica*, the North American *Azaleas calendulacea*, *nudiflora*, *viscosa*, *occidentalis* and *speciosa*, and the Chinese or Japanese *Azaleas sinensis* or *mollis*. These have been much intercrossed, and the respective types are now connected by so many intermediate forms that it is not easy to classify them under their respective species. In the older forms the parentage can be more readily detected.

All these species are extremely variable, frequently sporting, and by natural cross-fertilisation they had yielded a number of varieties before they were taken in hand by hybridisers here. They were first popularly known as American Azaleas, and subsequently, after they had received much attention in Belgium, and the number of forms had been artificially increased very largely, they became known as Ghent Azaleas, while now the progeny of *A. mollis* are commonly termed Japanese Azaleas, and a collective term for them is hardy hybrid Azaleas. The European *A. pontica*, which is found in Turkey and the Levant, is a deciduous shrub with ovate ciliate leaves and yellow open shallow corollas, not unlike *Rhododendron ponticum*, but readily distinguished by the characters named. It does not appear to have been introduced to England as early as some of the American species, but it has produced a number of varieties ranging in colour from pure white to dark coppery orange, and it has been useful in crossing with the other species.

Of the American Azaleas, one of the first brought to this country was *A. nudiflora*, which, according to the elder Aiton, was introduced by Mr. Peter Collinson in 1734, and before the close of the century several varieties of it had been added to collections. The flowers vary in tint from white to blush, pink, rose, red, and scarlet; they are tubular in shape, and suggestive both in form and fragrance of the Honeysuckle, under which name, with the prefix Wild or Upright, it is known in the United States. It is frequent in swampy districts in several States, and Gray remarks that the varieties are numberless. This is a charming type, owing to the rich colours prevailing in the flowers, their powerful fragrance, and the freedom with which they are produced before the leaves are fully expanded. It is also known as the May-flower in America, in allusion to the time at which it blooms. Several scores of varieties have received botanical names and been admitted into authoritative works, and the characters of the respective species are well preserved throughout. As the White Honeysuckle, another American species, *Azalea viscosa*, is familiarly known in its native home, where it is chiefly found in swamps near the coast in the northern and eastern States. This materially differs from the preceding (introduced at the same time) in producing its flowers when the leaves are fully expanded; and though the plant is beautiful, it does not present such a mass of colouring as *A. nudiflora*. The shades, too, have not so wide a range, being confined to white or yellow with rosy tinge, but the flowers are borne in large trusses, and are very fragrant.

The flame-coloured Azalea, *A. calendulacea*, is of a similar habit to *A. nudiflora*, but has larger, more open flowers, and of yellow, orange, or reddish hues. It is a native of woods and mountains in Pennsylvania, and from it has been obtained a large number of handsome varieties. *A. speciosa* and *A. occidentalis*, allied species, have also been concerned in the production of hardy varieties, but the foregoing are the principal types. With regard to *Azalea mollis*, many very handsome forms have been raised from it during the past twenty years, surpassing all the others in the size of the flowers and trusses, but wanting fragrance, and the colours only consist of shades of yellow, orange, or reddish orange. They are, however, extremely handsome, very early, and especially useful on this account for forcing, as though hardy they are sometimes damaged by our late spring frosts.—C.

Tomato Culture.—Frequently Tomato plants are severely thinned of leaves and branches, in order, it is said, to let in the sun to ripen the fruit. But ripening, says Mr. Meehan, is an important process. Good healthy leaves and foliage are essential to this, and the fruit will ripen better under the shade of such foliage than when exposed to the sun without the leaves. Where the branches are so numerous it is of advantage to thin out weaker ones to give more strength to the rest.

Varying Colours on Laburnums.—I was asked recently to account for the different coloured bunches of "Golden Chain" blooms on the trees varying, as they do, from a beautiful bright yellow through shades to a lilac colour, even on the same boughs. On examination with my magnifying glass I proved to my own satisfaction that it is caused by insects or mites, which restrict the sap and growth. It, however, seems very singular that they should change the colours to such an extent.—J. HAM.

Pæonia lutea.—To the many gorgeous flowered plants included in the "tree section" of the genus *Pæonia* has now to be added a plant having beautiful golden yellow flowers, which is now flowering at Kew for the first time, from a small piece received two years ago from the Paris Botanic Garden. In habit it closely resembles *P. Moutan*, but appears more slender in growth. What the size of the flowers will be as the plant gets larger and stronger is doubtful. At present the only flower open is 3 inches across, with ten petals of good substance. The petals and stamens are of the same golden colour, but at the base of the stamens a reddish brown mark is to be seen. This species resembling *P. Moutan* so closely ought to be valuable to the hybridist; if the colour of this could be got into the larger flowers of the other a very handsome plant would be the result. Like many other novelties of recent years it is a native of Yunnan.—W. D.

Preventing the Onion Maggot.—Professor J. B. Smith, of New Jersey, U.S.A., gives two methods of treating Onion beds to keep away or kill the Onion maggot. For small patches in the garden he would take fine sand and moisten it with kerosene, and sow it along both sides of the row, near but not touching the plants. This not only drives away the fly which lays the egg, but kills many of the maggots, as they leave one plant to go to another, as they will when the first is dead. The fly looks like a small house fly. A cupful of kerosene to a pailful of sand is enough. For larger fields, says the "American Cultivator," he would make a furrow alongside of the rows, turning the soil away from the plants, using a hoe or hand plough for that purpose, then sow broadcast about 600 lbs. of kainit and 200 lbs. of nitrate of soda to the acre, after which level the ground again. The first rain will carry the fertiliser to the plants, killing many of the maggots, and increasing the crop.

'Midst Fields and Hedges.—It is to be hoped that every one of my readers will be able to gratify the roaming instinct which makes most of us pine for "fresh fields and pastures new" in leafy June. Lovely Sussex should not be overlooked during the wanderings to all lovers of soft, undulating, downs, sleepy, unheard of villages, winding streams, and meadows richly jewelled with sweet Flora's choicest gifts. Every hedge is crowned with fragrant Hawthorn, beneath which nestles the creamy "Milkmaid's" starry blooms, pink "Ragged Robin," nodding Bluebells, wild Hyacinth, and azure-eyed "Speedwell." Fern, Milkwort, and waving Grasses are in profusion. Along the banks of the winding Ouse, the Arun, and the Adur are meadows deep and sweet-smelling, while small boats and punts float sleepily along the swift streams. Here and there the square wooden tower of an old-world Sussex church rises picturesquely against the velvety softness of a green-clad hill. To all this may be added, says a writer in "Reynolds," the pure wholesome air, the blue smoke of wood fires rising from the thatched roof of an oak and plaster built cottage, the hum of bees, the song of the lark and wildly whistling thrush, swallows, white breasted and blue winged, dart over the water from overhanging trees. Everywhere is peace and health, and the joy of life, which comes at times to even the saddest, weariest, loneliest among us. Do not forget that "God made the country and man made the town." Seek in Nature's own heart your pleasures, your rest, and recreation.

Pine Apples from Jamaica.—Highly satisfactory prices were obtained at the sale in Covent Garden Market on Friday of the first direct shipment of Pine Apples from Jamaica. The fruits sold for from 1s. 6d. to 2s. 6d. each. Some of the St. Michael Pines were larger, and consequently made more money. As the latter often makes from 3s. to 8s. each, the new industry is likely to prove of great benefit to the colony.

Practical Forestry.—One of the arguments against forest planting is, that one has to wait so long for returns. "Meehan's Monthly" has, however, always contended that companies could be formed and land planted, the stock of which company would be of increased market value from year to year as the trees reached a commercial age. The value of a plantation of this kind has been well shown by the sale of a ranch in California. Part of the property was unplanted; this brought 50 dols. an acre. Sixteen acres were in Alfalfa, the Lucerne of other regions; this brought 200 dols. an acre. A plot of 110 acres in hardshell Walnuts sold for 350 dols. an acre, and 80½ acres of softshell Walnuts for 400 dols. an acre. There is little doubt that forest planting, intelligently pursued, could be made profitable, forest fires being the only uncertain element in the operation.

Injury from Red Spider.—The red spider flourishes nearly as well in the open air in many parts of America as it does in greenhouses. It is an especial lover of the Spruce family. The past season they were so abundant in many parts, that when noticed the trees had the appearance of having been scorched by fire. This insect can, says a transatlantic journal, be very easily kept in check by spraying with kerosene emulsion, and if they can be kept clear from young trees, they are seldom troublesome to larger ones. When suffered to remain undisturbed from year to year they increase rapidly, and this seems to be the trouble now. The fact is, that spraying with kerosene emulsion has got to be a part of garden work, to be as regularly attended to as hoeing or pruning. Every garden should have its emulsion sprayer, and the trees should be carefully watched for the appearance of insects just as the regular garden crop is watched for the appearance of weeds. It is very little trouble to spray hundreds of trees in a short time with a good sprayer; and, generally speaking, when the insect is kept down in the younger trees it is not troublesome afterwards.

Hidalgoa Wercklei.—Under the name of *Childsia Wercklei*, this new species of *Hidalgoa* was distributed by an American firm in 1899. A popular description, and one that will convey the best idea of the plant, is to say that it is a climbing Dahlia. It is a native of Costa Rica, and makes a mass of long, slender, succulent branches, which are aided in attaining a height of at least 15 feet by means of the twisted leafstalks. The leaves are numerous, 2 to 3 inches long, and finely divided. The heads of flowers are similar to those of a single Dahlia, 2½ inches across. The ray florets are scarlet on the inside, orange scarlet on the reverse, the centre being composed of a tuft of bright yellow florets. It succeeds well in a cool airy greenhouse, grown on a pillar, rafter, or balloon, and is at home in a compost consisting of two parts loam, one part leaf mould, and one part decayed manure, with a little sand. Cuttings root readily if placed in a little bottom heat, and large plants can be had in a few months. As it is easily propagated and easily managed, being at the same time a brilliant coloured and free flowering plant, it ought to become popular as it gets better known.—R. G. K.

Hawthorn Enemies.—There are some curious facts to be noted with respect to the insect devastators of the Hawthorn, of whom there are at least two dozen species belonging to the lepidoptera alone. The caterpillars of the black veined white butterfly and of the little ermine moth do great havoc on the foliage, but, perhaps, the most remarkable of the larvæ which feed upon the leaves of the Hawthorn is that of the brimstone moth, which is often present, though seldom seen. Nothing more perfect than its knack of concealment is to be found among the many devices of the insect world. This cunning caterpillar simulates a twig of Hawthorn, bent into a curve like that of a twig, wearing a humpy excrescence resembling the projection of a twig, assimilating itself in colour, greenish or brownish, as may happen to be the hue of the twigs among which it places itself, erecting itself like a twig with the help of a cord so fine as to be almost undiscernible. Sometimes a shock is given to sensitive nerves by the discovery that a seeming twig feels soft to the touch and begins to wriggle. It is worth notice that the cocoon of this insect is similar in colour to its surroundings, dark or light, as they may happen to be.—("Globe.")

Fremontia californica.

Two of the most conspicuous of the flowering shrubs flowering in the Himalayan house at Kew at the present time both hail from California. One is the attractive *Carpenteria californica* with large pure white flowers, and the other is *Fremontia californica*, the flowers and leaves of which are represented in the illustration (fig. 145). This *Fremontia* came to us with the reputation of being quite hardy, but such has not proved to be the case, though we believe it will thrive fairly well on a wall in a favourable climate. This is the more regrettable, as the splendid pure yellow flowers are different from those of any other shrub that is grown in our gardens.

Writing of the *Carpenteria* and the *Fremontia* in the *Journal of Horticulture* a year or two back, "W. D." says, "Although not cultivated to any great extent, the two plants, *Fremontia californica* and *Carpenteria californica*, are known by repute to most horticulturists as showy flowering shrubs. Like many other good things from the same country, they are not sufficiently hardy to withstand without injury, in the open, any but the very mildest of winters as far north as London, and even with the protection of a wall they are generally killed by a spell of severe frost. In the S.W. counties, however, and in some parts of Ireland they do well, especially if a snug corner can be given them. At Kew a good sized plant of each has been included among the occupants of the new Himalayan house, and in that place both are now in flower. *Fremontia californica* is represented by a specimen 6 feet high. It is of pyramidal habit, the branches being thrown out at right angles with the stem. The flowers are borne singly from last year's wood; they are deep, rich yellow, and $3\frac{1}{2}$ inches across. The leaves are more or less cordate, rather deeply lobed, and very hairy on the under surface. The example of *Carpenteria* is about $4\frac{1}{2}$ feet high by $3\frac{1}{2}$ feet through, and is thickly covered with upright racemes of pure white flowers. Of the two plants this is certainly the more useful, and is worth growing either as a pot or border plant for a cold greenhouse. If grown in a pot, it will be greatly benefited by being plunged outside for the summer."

The Vine as an Ornamental Plant.

MR. A. F. BARRON'S excellent work, "Vines and Vine Culture,"* has reached its fourth edition. It remains substantially the same as before, but with certain additions. The most noteworthy is a short illustrated chapter on the "Vine as an Ornamental Plant." This it undoubtedly is as represented by certain species and varieties. We are reminded of the fact that "years ago in the Royal Horticultural Society's Gardens at Chiswick, and also at South Kensington, Vines were trained to tall columns and festooned from pillar to pillar, presenting a very handsome appearance;" and the author of the book goes on to say he "has often wondered when looking at these noble plants why the Vine was not more generally grown in this way, and that its beauty should be so little known."

Mr. Barron also reminds us of another fact, for fact it is, that the Vine is an excellent town plant, "growing luxuriantly in some of the foulest parts of London." Now that pergolas appear to be coming into fashion it is almost a wonder they are not to be seen in appropriate positions in the London parks and gardens. Arcades of Vines over sections of some of the walks would not only form a distinct and attractive feature, but afford grateful shade for visitors during those burning hot days in summer, when it is the greatest relief that can be found. Both in many public and private gardens trees appear to have been planted as far from the main paths as possible. Arcades of Vines here and there over such paths would be entirely inviting, whereas at present we have veritable sun traps, rendering the promenades more punishing than restful with a sun temperature of 120° to 130° .

With a strong framework of oak or larch, and this not trimly covered, but freely and informally draped, with Vines, rambling Roses, Honeysuckles, Jasmines, and other appropriate plants, a feature of interest would be added to both public parks and private pleasure grounds where provision for summer shade is lacking. In city and town gardens Roses may not thrive, but there are few in which Vines and the wilder Clematises, such as the "Travellers' Joy," and the common Virginia Creeper, will not flourish, and with these aids cool retreats might be formed that would be greatly enjoyed.

But Vines, as Mr. Barron suggests, are the best, and the best of these for luxuriance and beauty are the American and Japanese species, though some European varieties are effective. Of these latter he

mentions Miller's Burgundy, Espiran, and the purple-leaved Spanish Tenturier. The brilliant Japanese species, *Vitis Coignetiae*, has, as it deserves, prominent attention for ornamental purposes, and a good word is said for the rich-leaved American *V. Labrusca* or *Thunbergi*. Others are also recommended, and it may be noticed that Mr. Barron gives to the familiar close-growing wall plant, known as *Ampelopsis Veitchi*, its modern and presumably proper name of *Vitis inconstans*.

As to the bulk of "Vines and Vine Culture" devoted to the growing of Grapes and descriptions of varieties, nothing more need be said than that it is the standard work on the subject, and will carry its respected author's name to posterity. The possession of this soundly practical work should be regarded as a necessary part of the equipment of all who desire to excel in the management of Vines and the production of superior Grapes.

Mr. Robert Fenn on Potato Hybridising.

IT was in 1837 I planted my first orchard—grubbed up a lot of worn-out Apple trees and renovated their sites, 3 yards in diameter and 2 feet deep, with chopped turves taken from a meadow, and mixed with ditch scourings and road dirt (exactly what the poor old Chiswick garden wants doing to now). As the spring time waned this ground, about an acre, became trenched and planted with the then most popular sorts of Potatoes, for the purpose of making selections for improvements from the most promising stools. I lost a good ten years over that futility.

I have often longed for a rich firm to back me up in my experimental Potato work. An old song makes "Robin Rough" sing "If I had but a thousand a year, Gaffer Grey." Alas! neither by wishing nor singing, neither one nor the other of those helps will ever come to my share. I did rub my eyes, though, when a few weeks ago I read in a contemporary, "Fenn of Sulhamstead has ceased to intercross or otherwise raise new varieties." "Fenn of Sulhamstead" answers Yes and No; Yes in regard to my first response, No means I have merely jumped from South to North America, and for the last two decades have been endeavouring to cross-fertilise our domestic varieties with wild species from the latitudes of New and Old Mexico.

I have succeeded in regard to New Mexico through *Solanum Fendleri*, and as regards Old Mexico thus far with *S. castanum*, by securing last season a pollen-cross from the latter with one of my seedling varieties. I feel certain I shall produce for posterity efficient food to be handed down, should Providence insure me life, and I can maintain the opportunity. I put a stress on the word, for continuity in this Potato-breeding business means deep delvings into the pocket of the inventor. Please, however, to let it be known to my old friends and readers of "our Journal," that instead of having gone under, at present it looks very much like my being on the surface. But I can find no more satisfactory occupation in producing by intercrossings other than what I have acceded to from South American sorts with our domesticated varieties, unless, peradventure, it would be in the creation of size. You know how my experience for a very long time has been set against the pot-wallopers. I am now busy in planting my selections, which I shall hope to name Her Majesty Queen Victoria Jubilee Potatoes.—ROBT. FENN.

[A later note] I feel disappointed to-day at not seeing in print the paper I sent to the Editor some time ago upon the above subject. I suppose it must be because you have so many brilliant writers now on more brilliant subjects that you cannot entertain "Joseph." I will try and not take it too much to heart. Should you, however, bring yourselves to consider what I wrote last, about my progress with the noble tuber, of sufficient calibre, I send now a tag to add as to what happened at Cottage Farm on the 24th ultimo.

That being Ascension Day, of course as an orthodox churchwarden I attended at the ordinances of our Church. On my walk home, amongst others in conversation, I invited two congenial young Irishmen who were of the congregation to join me at a function I was going to hold in my greenhouse, an achievement not possible, at the date, to be attested in any other part of the world, in commemoration of her Majesty Queen Victoria's birthday. "Potatoes; O-h-h!" [Well, I told you all about them in my last important (*sic*) unpublished composition]. Note, I had been successful after a three years' tussle in hybridising the last wild trans-comer from North America, *Solanum castanum*, with an English seedling of my own raising. This function was the sowing of the seed which my audience, the missus included, now witnessed. When completed, there arose in my mind to quote, "Paul planted, Apollos watered, but God alone giveth the increase." Then after presenting each of my audience with a Rose for their buttonholes, we retired into my cottage, and—my daughter Alice being from home—one of the bhoys from Ould Ireland presiding at the piano, we rendered "God Save our Gracious Queen" vociferously.—ROBT. FENN.

* 12, Mitre Court Chambers, Fleet Street, E.C. 5s., by post 5s. 6d.

Fig. 145.—FREMONTIA CALIFORNICA.

Onions from Bermuda.

WE have received through Messrs. Northard & Lowe, Tooley Street, S.E., a sample of Onions from Mr. G. A. Bishop, superintendent of the Government Botanic Station and Public Garden, Bermuda, who "would like to see a note respecting them in the dear old Journal." We understand this is a portion of the first consignment to this country, sent with the object of establishing a market for the produce in Britain during March, April, and May. At present Egyptian Onions largely hold the field for general household purposes. They are firm, conical Onions, varying in size from 1 to 2 or 3 inches in diameter, of a dull straw colour, and sell for 7s. or 8s. a bag of about 100 lbs.

The Bermuda Onions are entirely different. The bulbs are perfectly flat, and resemble the original type of the white Spanish, now not often seen. They vary in size from a little under 2 inches to a little over 3 inches in diameter, the larger being about 1½ inch thick at the margin, and very little more at the centre. They are greenish yellow in colour, very firm, with thin transparent skins the bulbs perfectly ripened, and bright in appearance. Some of them when roasted were found unusually tender, mild, and sweet, and the cook praised them highly, as not affecting the eyes in peeling. Whether the cost of production and transit will prejudice the Onions of our ancient colony (annexed in 1609) as against the "Egyptians" we do not know, but we are strongly of opinion that it would be hard to find better samples in appearance, quality, and the varied sizes requisite for general household use, than those which have been sent by Mr. Bishop from one of the main islands of the Bermudas group in the West Atlantic, nearly 600 miles from North Carolina. These islands are said to be a favourite winter resort of Americans; chief products, vegetables; climate, temperate and equable; mean temperature (1896) 69·7; rainfall (same year) 59·38. There is no note on the soil in our reference, but it can clearly be made to grow superior culinary Onions, though they are the reverse in character of the Brobdignagian bulbs as produced by our great growers for exhibition.

The Royal Horticultural Society.

Drill Hall, June 19th.

THE exhibition in the Drill Hall on Tuesday was a most excellent one, and was admirably representative of the plants now in flower. Fruits were not numerous, but some splendid Melons and Peaches were exhibited. Orchids were seen in both quantity and quality, as were exhibits for the special inspection of the Floral Committee.

Fruit Committee.

Present: G. Bunyard, Esq. (in the chair); with the Rev. W. Wilks, and Messrs. J. H. Veitch, H. Esling, A. F. Barron, W. Pope, G. Kelf, A. Dean, S. Mortimer, W. Bates, W. Farr, G. T. Miles, G. Wythes, F. Q. Lane, H. Markham, E. Beckett, G. Norman, and J. Willard.

Mr. H. Walters, gardener to Lord Gerard, Eastwell Park, Ashford, contributed an excellent collection of Melons, including the leading varieties. Mr. H. Folkes, gardener to C. E. Strachan, Esq., Gaddesden Park, Hemel Hempstead, sent Peaches Dr. Hogg and Royal George, with Melons Hero of Lockinge, Taunton Hero, and Eureka. Mr. W. Fyfe, gardener to Lord Wantage, V.C., Lockinge Park, Wantage, arranged a splendid collection of fruit. Amongst others we noted well finished Grapes Madresfield Court and Foster's Seedling, Nectarine Impératrice, Peach Stirling Castle, Figs Brown Turkey and White Ischia, and Melon British Queen. The fruits were set off with Iris flowers.

Floral Committee.

Present: W. Marshall, Esq. (in the chair); with Messrs. J. Walker, S. M. de Graaff, H. B. May, C. Jeffries, R. Dean, G. Renthe, J. W. Barr, W. Howe, J. Fraser, J. Hudson, J. Jennings, H. S. Leonard, C. E. Pearson, J. D. Pawle, J. T. Bennett Poë, C. E. Shéa, G. Gordon, H. J. Jones, H. J. Cutbush, W. J. James, G. Paul, E. T. Cook, C. Blick, and E. Mawley.

Mr. Chas. Blick, gardener to Martin R. Smith, Esq., Hayes, Kent, arranged a large semi-circular group of Carnations in grand style. The blooms were simply immense, and the "grass" clearly indicated the splendid condition of the plants. The new yellow variety Cecilia could only be described as magnificent, while Mrs. Martin Smith, Calypso, Grace, King Oscar, Florizel, Lady Rose, and Mrs. Trelawny were also remarkable for their beauty. The Palms forming the back, and the Maidenhair and Caladium argyrites in the front, made an excellent finish to the group. Messrs. Barr & Sons, Covent Garden, arranged a table of hardy flowers in which Pæonies and Irises formed the principal features, while a general collection of cut flowers made up a good display. The Spanish Irises included fine bunches of Thunderbolt, Blue Beauty, California, a grand yellow; Cantab, and Snowball. The most conspicuous Pæonies were Sir Henry Irving, a pretty rose; humca carnea, flesh pink; delicatissima, creamy white; Boccage, rosy red; and Duke of Wellington, a good white. Iceland Poppies, Calichorti, Lupinus arboreus luteus, and Pyrethrums were all worthy of commendation.

Hardy flowers were again well staged by Messrs. T. S. Ware Ltd., Feltham. There were German Irises, *Armeria cephalotis rubra*, *Cypripedium spectabile*, *Scabiosa caucasica*, *Aster alpinus*, a few *Liliums*, which included *L. elegans maculatum aureum*, *L. elegans robustum*, *L. colchicum*, and *L. pomponium*, while a collection of rock plants completed the display. A tasteful group of Carnations arranged with Palms, variegated Acers, Ferns, Crotons, Dracænas, and other foliage plants was displayed by Messrs. B. S. Williams & Son, Upper Holloway. The best Carnations were Alice Avres, Rose Celestial, R. H. Measures, and Tom Sayers in the border section, while the Malmaison type was represented by Sir Evelyn Wood, Blush White, Princess of Wales, and the Churchwarden. Messrs. Jas. Veitch & Sons, Ltd., Chelsea, put up a splendid bank of Spanish Irises, *Ranunculus*, and *Ixias*, which were arranged in a bank of Maidenhair Fern, and produced a capital effect. The most noteworthy varieties were Darling, Leander, Blanchard, Agnes, Belle Chinoise, Formosa, and Mia. A good display of mixed English varieties was also staged, and the *Ranunculuses* formed an attractive feature.

Messrs. F. Cant & Co., Colchester, had a fine display of garden and other Roses arranged in vases, which formed a perfect Rose garden in itself. A few of the best varieties were Paul's Single White, Papillon, Reine Olga de Wurtemberg, Princess de Sagan, fimbriata, W. A. Richardson in capital form, Paul's Carmine Pillar, Marquis of Salisbury, Gustave Regis, and Alister Stella Gray. From Messrs. Paul & Son, Cheshunt, came a large collection of garden Roses, in about 110 varieties; a most interesting display. The new garden Rose Una, a creamy semi-double variety, shading to apricot in the centre, was conspicuous; as were The Lion, a seedling from Carmine Pillar; Aglaia, L'Ideale, Blairi No. 2, Gustave Regis, Morletti, Mignonette, Mrs. Bosanquet, Rugosa alba, microphylla, Fimbriata, and Carmine Pillar. Hybrid Aquiegias were staged in grand condition by Messrs. H. Cannell and Sons, Swanley. The strain is undoubtedly a good one, and as staged left little to be desired, the colours being most varied, while the huge bunches displayed them admirably.

Messrs. W. Paul & Son, Waltham Cross, staged a miscellaneous collection of plants and cut flowers. The back was formed of specimen plants of *Bougainvillea Sanderiana* in full flower, *Nicotiana colossea foliis variegatis*, a gigantic Tobacco plant; while the baskets of Roses arranged with Ferns made a pleasing group. The Roses included baskets of Madame Hardy, Adele Prevost, Spong, Blanchfleur, and Gloire des Polyantha. From Messrs. Kelway & Son, Langport, came a grand display of Pæonies, Delphiniums, and Gaillardias. The Pæonies were arranged in huge clusters, and the following were most conspicuous—Duchess of Somerset, Joan Seaton, Dr. Bonavia, Maria Kelway, Lady Romilly, Mrs. George Lewis, Red Ensign, and Sir George White. The Delphiniums formed an attractive feature, and contributed well to the exhibit. A most interesting exhibit was that arranged by Messrs. Wallace & Co., Colchester, the Irises, *Liliums*, *Calochorti*, and Pæonies being particularly attractive, while good bunches of *Incarvillea Delavayi*, *Brodiaea ixiodes*, and a few bearded Irises materially assisted the display.

Messrs. Geo. Cooling & Sons, Bath, arranged a fine exhibit of garden Roses, staged in their well known style. The bunches were huge, though lightly arranged. The varieties included rugosa fimbriata, Dr. Rouges, Papillon, Queen Mab, Harrisoni, Heb's Lip, Perle d'Or, Camoens, Blanche de Coubert, and Marquis of Salisbury, among many other well known varieties. Mr. G. Prince, Oxford, arranged a large exhibit of Tea Roses in boxes, staged in the orthodox style, also in pyramid form, together with a splendid collection of Sweet Peas arranged with Asparagus. The Roses included fine specimens of Muriel Grahame, Maréchal Niel, Comtesse de Nadaillac, Princess Beatrice, Maman Cochet, Cleopatra, Mons. Furtado, and Catherine Mermet. The Sweet Peas were in the pink of condition, and included such varieties as Triumph, Countess of Radnor, America, Salopian, Firefly, and Ovid. Mr. Amos Perry, Winchmore Hill, staged a large collection of hardy flowers in bunches, forming an attractive exhibit; notable were *Dictamnus fraxinella*, *Campanula speciosa*, *Heuchera sanguinea*, double Rockets, Irises in variety, also Papavers, and *Lychnis viscaria splendens plena*. Many others might be mentioned, but space forbids.

From Mr. M. Prichard, Christchurch, Hants, also came a collection of hardy flowers, arranged in large bunches which looked imposing and attractive. Some of the chief were *Dianthus Napoleon III.*, *Orchis foliosa*, *Potentilla Congo*, a dark crimson variety; *Delphinium formosum*, Piuks in variety, and a collection of Spanish Irises. Mr. J. Fitt, gardener to F. W. Campion, Esq., Trumpet's Hill, had a good collection of garden Roses, and although they were staged in a bad light it had the advantage of preserving the flowers, which kept fresh and bright throughout the day. The bunches of Rêve d'Or, W. A. Richardson, Carmine Pillar, and Marquis of Salisbury were capital. A large group of Pæonies and Irises was arranged by Messrs. Jas. Veitch & Sons, Ltd., Chelsea. The Pæonies were simply gorgeous, while the Irises included Arnolds, Nationale, Louise Mayer, Mrs. H. Darwin, Garrick, Topaz, and Bridesmaid. The same firm also sent greenhouse *Rhododendrons* and *Kalanchoe flammea*.

Mr. John Fleming, gardener to Lady Pigott, Wexham Park, Slough, occupied a large space at the side of the hall with a charming decorative exhibit beautifully arranged, while the material employed was of first-rate quality. Tall Humeas and Palms formed a light

and graceful top, while the groundwork contained Carnations, *Lilium Harrisii*, Statice, and Zonal Pelargoniums, with Crotons, Caladiums, Ferns in variety, small Palms and Dracænas, a pretty edging of *Isolepis gracilis*, completed a magnificent group. A pretty group of Roses called *Electra* raised from *Rosa multiflora simplex* and W. A. Richardson was much admired from Messrs. Jas. Veitch & Sons, Ltd., Chelsea. The colour is lemon yellow, a little deeper shade to the centre giving it a good appearance. Mr. H. J. Jones, Ryecroft Nursery, Lewisham, arranged a group of Sweet Peas grown in pots, with a few good single and double Begonias, Spiræas, and Celosias, also a pair of well-flowered plants of Malmaison Carnation H. J. Jones, a deep crimson. The Sweet Peas included Gorgeous, Emily Eckford, Queen Victoria, Modesty, Apple Blossom, Countess of Aberdeen, and Mars. The whole were well arranged with Maidenhair Ferns. Messrs. V. N. Gauntlett & Co., Japanese Nurseries, Redruth, staged a collection of Rhododendrons and a few choice flowering shrubs, such as *Orsothamnus thrysoides*, *Kalmia latifolia*, *Escallonia exoniensis*, and *Eurybia macrodonta*, also a collection of Bamboos ranging from 6 to 20 feet long; an interesting exhibit.

Mr. Anthony Waterer, Knapp Hill Nursery, Woking, sent four boxes of Rhododendrons and Acacias in four varieties. Mr. Walters, gardener to Lord Gerard, Eastwell Park, Ashford, staged boxes of cut Roses in good condition, also some bunches of garden Roses. The new Carnation Lady Gerard was also again on view. Mr. B. R. Cant, Colchester, sent a pretty display of garden Roses, well arranged and in capital condition. The chief varieties were Ma Capucine, Bardou Job, Madame P. Perny, Gustave Regis, Rainbow, and Madame Falcot.

Orchid Committee.

Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de Barri Crawshaw, H. Ballantine, H. Little, J. T. Gabriel, F. J. Thorne, H. J. Chapman, W. H. Young, W. H. White, J. Douglas, T. W. Bond, J. Jaques, H. A. Tracey, H. T. Pitt, T. Rochford, W. Cobb, J. Colman, J. G. Fowler, E. Hill, and A. Truffaut.

Mr. G. E. Dav, gardener to H. F. Simonds, Esq., Beckenham, arranged a bright group of Orchids, in which forms of *Lælia purpurata*, *Odontoglossum vexillarium*, *Cattleyas* and *Oncidium concolor* were most conspicuous. Mr. F. W. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill, contributed a small collection of Orchids, comprising *Odontoglossums*, *Dendrobiums*, *Cattleyas*, *Lælias* and others. Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, staged *Odontoglossum crispum* in splendid form, with *Sobralia Veitchii*, *Lælio-Cattleyas Arnoldiana* and *Canhamiana*, Edouard André, *Lælia tenebrosa* Walton Grange variety (fig. 146), *Cattleya Mossiae* Lawrenceæ, *Polystachya zambesica*, *Pogonia* species, *Epidendrum fragrans*, and others.

Mr. A. Ward, gardener to F. A. Bevan, Esq., Trent Park, New Barnet, showed a superb specimen of *Cœlogyne Dayana*; it carried an immense number of magnificently flowered spikes. Messrs. H. Low and Co., Bush Hill Park, made a brightly attractive display with *Cattleyas*, *Lælias*, and *Odontoglossums*; the flowers were of good form and well coloured. A small group was arranged by Messrs. B. S. Williams and Son, Upper Holloway. It included *Vanda suavis*, *Cattleya Mendeli*, *Vanda teres*, *Odontoglossum citrosum*, *Lælia tenebrosa*, and a charming collection of *Cypripediums*. Messrs. Stanley Ashton & Co., Southgate, showed *Cattleyas*, *Odontoglossums*, *Cypripediums*, *Miltonias*, and other Orchids in variety.

A few superb Orchids were staged by Mr. H. Ballantine, gardener to Baron Schröder, The Dell, Egham. They included *Lælio-Cattleya eximia*, L.-C. Lady Wigan, L.-C. Hippolyta, *Cattleya Mossiae*, In Memoriam Richard Curnow, *Cypripedium callosum* Sanderæ, C. Curtisi, *Odontoglossum crispum* Rex and one or two others. Mr. Davis, gardener to J. Gurney Fowler, Esq., Woodford, sent some magnificent *Cattleyas* with *Cypripedium callosum* Sanderæ, *Cochlidoda Noezliana*, and a few other Orchids. Mr. W. P. Bound, gardener to J. Colman, Esq., Reigate, arranged a small group in which forms of *Odontoglossum crispum* were most noticeable. Mons. F. Claes, Brussels, showed some finely grown *Odontoglossum crispum*. Exhibitors of one or two plants of Orchids were not very numerous. They included Mr. W. Stevens, gardener to W. Thompson, Esq., Stone, *Odontoglossum crispum* The Earl, and O. Rolfeæ Walton Grange variety; Mr. W. H. Young, Orchid grower to Sir Fred. Wigan, Bart., East Sheen, *Phalaenopsis grandiflora* (superb white form), *P. speciosa* and *Sobralia Veitchii aurea*; Messrs. Charlesworth & Co., Bradford, *Cypri-*

pedium Chapmanii heatonense and *Dendrobium Phalaenopsis Schröderianum album*; Mr. J. May, gardener to J. B. Joel, Esq., Northaw House, *Cattleya gigas imperialis*; Mr. J. Douglas, Great Bookham, *Dendrobium tortile*; and Mr. J. T. Barker, gardener to W. P. Burkinshaw, Esq., Hessele, *Cattleya Mendeli Mandiæ*.

Medals.

Fruit Committee.—Silver-gilt Knightian medal to Mr. W. Fyfe, silver Banksian medal to Mr. H. Folkes, and silver Knightian medal to Mr. H. Walters. Orchid Committee.—Silver Flora medals to Messrs. B. S. Williams & Son, W. H. White, G. Day, J. Davis, and H. Ballantine; and silver Banksian medals to Messrs. Stanley, Ashton and Co., W. P. Bound, F. W. Thurgood, F. Claes, and H. Low & Co. Floral Committee.—Silver-gilt Flora medals to Messrs. G. Prince, W. Blick, J. Fleming; silver Flora medals to Messrs. H. J. Jones, J. Veitch & Sons, W. Paul & Son, F. Cant & Co., F. W. Campion, and Cooling & Son; silver-gilt Banksian medals to Messrs. Kelway & Son and A. Perry; silver Banksian medals to Messrs. R. Wallace & Co., Barr & Sons, B. R. Cant, H. Cannell & Sons, M. Prichard, Paul & Son, and T. S. Ware; and bronze Banksian medal to A. Walters, R. Gauntlett & Co. and A. Waterer.

Certificates and Awards of Merit.

Auchusa italica grandiflora (Mrs. Bulteel).—An improved form of

FIG. 146.—*LÆLIA TENEBROSA*, WALTON GRANGE VARIETY.

an old-fashioned plant that is too well known to require description (award of merit).

Campanula persicifolia Moerheini (T. S. Ware).—A semi-double form of the well known double pure white Peach-leaved Campanula (award of merit).

Delphinium Queen of Huish (Kelway & Son).—A very bright blue variety with large flowers (award of merit).

Eremurus Warti (T. S. Ware).—This is said to be a new species from central Asia; the spike is about 4 feet long, and is clothed with yellow flowers (award of merit).

Geranium sanguineum album (A. Perry).—A white form of a well known plant (award of merit).

Heuchera micrantha rosea (R. Wallace & Co.).—A very floriferous form of the type; the flowers are much deeper pink in colour (award of merit).

Iris germanica Black Prince (A. Perry).—A handsome variety of the germanica section; the standards are purple and the falls dark purple (award of merit).

Iris paradoxa (Van Tubergen).—A most beautiful Iris. The standards are white with blue veins; the falls, covered with short hairs, are velvety blackish purple (first-class certificate).

Iris urmiense (Van Tubergen).—A pale yellow species of the *Oncocyclus* section (award of merit).

Pæony Eastern Queen (R. Wallace & Co.).—A magnificent variety with intense crimson single flowers (award of merit).

Sobralia Veitchii aurea (W. H. Young).—A superb yellow variety of this well-known *Sobralia* (award of merit).

The York Floral Fête.

June 13th, 14th, and 15th.

On Wednesday June 13th the York Floral Fête was held for the forty-second time, and, as usual, a brilliant display was brought together. The majority of the classes were well filled, but as is customary in a gathering of such magnitude as this, the competition was not very keen in some instances. The reputation the Yorkshire exhibitors have made for themselves with Pelargoniums was well maintained on the present occasion, while fruit was admirably staged for such an early date in a late season. Orchids were particularly attractive, as were groups and specimen plants, though some confusion was observable in the arrangement of the latter. The trade, as usual, contributed handsomely to the general display.

For a group of plants arranged for effect, occupying a space not exceeding 300 square feet, the first prize went to Mr. W. Townsend, gardener to E. Beckett Faber, Esq., Belvedere, Harrogate, who effected a very meritorious arrangement. A fine *Kentia Fosteriana* stood in the centre of the background, and the front of the group had as a centre a cork grotto from which spikes of *Odontoglossum crispum* issued, two other mounds being crowned with fine *Cocos Weddelliana*. The undulating surface was relieved by single-stemmed *Crotons*, *Lilium Harrisii* and *Dracaena Sanderiana*. *Caladium argyrites*, *Pancratium fragrans*, and *Eulalia japonica variegata* were skilfully employed. The second prize was awarded to Mr. W. Vause, Leamington, who had larger Palms in the background. *Phoenix rupicola* stood on a central mound towards the front of the group, and was flanked by low rustic arches. This group had more variety than the first, but was a little crowded. The third prize was secured by Mr. W. Curtis, gardener to Jas. Blacker, Esq., Thorp Villa, Selby.

In the classes for twelve, six, and three, stove and greenhouse plants in bloom, Mr. Cypher, Cheltenham, was first, and Mr. Vause, Leamington, second in each instance; Mr. C. Lawton, gardener to Col. Harrison, Broadley, Welton House, Brough, being third in the class for twelve. For a single specimen stove plant in bloom, Mr. Vause went to the front, and was followed by Mr. Cypher and Mr. J. McIntyre, gardener to Mrs. Gurney Pease, Woodside, Darlington. For a single specimen greenhouse plant in bloom, Mr. Vause again received the premier prize. Mr. Cypher regained the chief position with six ornamental foliage plants, Mr. C. Lawton being first for three. In the class for three *Crotons*, Messrs. R. Simpson & Son, Selby, were first, and Mr. J. McIntyre second. Mr. Cypher came first with a single specimen Cape Heath with *Erica depressa*, and Mr. Vause second. For six exotic Ferns Mr. J. McIntyre took first prize with handsome plants of *Davallia Mooreana*, *D. bullata*, *D. fijiensis*, *Gleichenia rupestris*, *Microlepia hirta cristata*, and *Adiantum concinnum*. The second position was adjudged to Messrs. R. Simpson & Son, and the third to Mr. J. Snowden, gardener to the Rev. G. Yeats, Heworth Vicarage, York. Mr. J. McIntyre retained the lead with three exotic Ferns, Mr. J. Snowden being second, and Mr. J. Eastwood, gardener to Mrs. Tetley, Fox Hill, Weetwood, Leeds, third. For a group of Carnations in bloom, not less than fifty pots, arranged amongst Ferns, the first prize was awarded to Mr. J. P. Leadbetter, gardener to Arthur Wilson, Esq., Tranby Croft, Hull, who staged in his customary excellent style. The *Malmaisons* were large and full, and the foliage healthy. Tree Carnations Duke of York and Germania were conspicuous. Mr. J. W. Hutchinson, Kirby Moorside, secured the principal prize for a collection of Roses in pots grouped for effect. Messrs. Jackson & Son, Bedale, were second, and Mr. H. Pybus, Monkton Moor, Leeds, third.

For a table of Orchids, 12 feet by 5 feet, good arrangement to be the test, the first prize went to Mr. Cypher. This table had at the back two arches composed of *Asparagus plumosus* set with spikes and single blooms of various *Cattleyas*, *Lælia purpurata*, and *Dendrobium Dalhousianum*. The Orchids in pots sprang from a groundwork of Ferns, and amongst the various plants were *Cattleya Mossiæ*, *C. Mendeli*, *Lælia tenebrosa*, *Epidendrum vitellinum majus*, *Oncidium concolor*, *Miltonia vexillaria*, and *Thunias*. Mr. John Robson, Altrincham, was second. Mr. Cypher was again first for ten Orchids in bloom, with *Cymbidium Lowianum*, *Lælio-Cattleya* (seedling), *Thunia Marshalliana superba*, *L. purpurata alba*, *Cypripedium Lawrenceanum*, *Miltonia vexillaria*, *Odontoglossum crispum*, and *Cattleya Mossiæ splendens*. Mr. J. T. Barker, gardener to W. P. Burkinshaw, Esq., West Hill, Hessle, was a creditable second. The last named grower showed six excellent Orchids in bloom, and secured the first prize. *Sobralia macrantha* in splendid form gained the premier prize in the class for a single specimen Orchid for Mr. C. Lawton.

Mr. Skill, gardener to Mrs. Lloyd, Lingcroft, York, headed the class for a group of herbaceous *Calceolarias* arranged for effect. For a hand basket of cut flowers the first prize was justly awarded to Messrs. Perkins & Son, Coventry. It was a most charming arrangement of *Oncidiums*, *Odontoglossums*, *Cattleyas*, and *Dendrobiums*, with *Asparagus plumosus*. Mr. Jas. Summers, Fawcett Street, Sunderland, was second with a basket that was a trifle crowded, Roses being intermixed with Orchids. Mr. Vause came third. For two bridal bouquets Messrs. Perkins & Sons distanced everybody with an inimitable arrangement. The second prizewinner, Mr. J. Summers, also staged admirably, Mr. Geo. Webster, New Market, Sunderland, being third.

Precisely the same order was maintained in the classes for two ball and two hand bouquets, the exhibits being again of exceptional merit. For a single bouquet Messrs. Perkins & Sons were first, and Mr. Webster second.

Messrs. Harkness & Sons, Bedale, secured the premier award in the class for seventy-two Rose blooms, in not less than thirty-six varieties; Messrs. J. & A. May, Hope Nurseries, Bedale, being second, and first for forty-eight, and also for thirty-six distinct varieties of cut Roses. For twenty-four distinct varieties Messrs. Harkness & Sons were first; while for eighteen distinct varieties Mr. J. W. Hutchinson, Kirby Moorside, was the most successful exhibitor. Messrs. Burrell & Co., Cambridge, were second; and Messrs. Harkness & Sons third. For a stand of twelve white and yellow Roses, in six distinct varieties, Messrs. Harkness & Sons were first, and Mr. J. Hutchinson second.

In the class for twelve bunches of stove and greenhouse cut flowers Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hall, Guisboro', was first; Mr. Alderman, gardener to J. D. Ellis, Esq., Sparken House, Worksop, second; and Mr. Keywood, gardener to W. H. Battie Wrightson, Esq., third. For a stand of flowers suitable for a dinner table Mr. Geo. Webster was first, and Mr. G. Cottam, Alma Gardens, Cottingham, was the best exhibitor of twelve bunches of hardy border flowers.

The first prize for a collection of hardy cut flowers, in a space not exceeding 18 feet by 6 feet, went to Messrs. R. Smith & Son, Worcester, who had a very exhaustive display, including everything at present in flower. The second prize was awarded to Messrs. Harkness & Son, Bedale.

Mr. McIndoe annexed the premier award for a decorative table of fruit not less than ten dishes. The exhibit was composed of Pine Charlotte Rothschild, Grapes two bunches each of Black Hamburg and Foster's Seedling; Peaches Grosse Mignonne and Early Alfred; Nectarines Lord Napier and Stanwick Elruge; Figs Brown Turkey, Plums Early Transparent Gage and Purple Imperial; Cherries Bigarreau Napoleon, and Downton; Melons Hutton Hall and Best of All, and a dish of Strawberries. This exhibit received 127 points out of a possible 136, and was awarded twenty-four points—the maximum—for decorative effect. Mr. J. Tullett, gardener to Lord Barnard, Raby Castle, secured the second prize with a magnificent dish of Fig Brown Turkey, and two grand dishes of Strawberries as the best features. The exhibit received 102 points, twenty of which were for decorative qualities. For a collection of six kinds of fruit, Mr. J. McIndoe was again first with three bunches each of Grapes Black Hamburg and Chasselas Napoleon; Peach Grosse Mignonne; Nectarine Lord Napier; Fig Brown Turkey and Melon Hutton Hall green flesh. Mr. J. Easter, gardener to Lord St. Oswald, Nostell Priory, Wakefield, who staged Grapes Black Hamburg and Foster Seedling; Peach Rivers' Early York; Nectarine Rivers' York; Fig Brown Turkey, and a seedling Melon, was awarded second, and Mr. Tullett third. For a small collection of four kinds of fruit Mr. J. McIndoe maintained the lead, and was followed by Messrs. J. F. Leadbetter and J. Easter in the order given.

Mr. Jordan, gardener to J. Corbett, Esq., Impney, Droitwich, was first for one Pine. For three bunches of black Grapes Mr. Oates, gardener to Lady Hawke, Wighill Park, Tadcaster, was first with perfectly finished Black Hamburg; Mr. W. Nichols, gardener to Viscountess Beaumont, Carlton Towers, Pontefract, being second; and Mr. W. Allsop, gardener to the Right Hon. F. J. Saville-Foljambe, Osberton, Worksop, third. For three bunches white Grapes Mr. W. Nichols was first with Buckland Sweetwater, fine in bunch and berry. Mr. J. McIndoe had to be content in the second place with Foster's Seedling. Mr. C. Lawton went to the front in the class for six Peaches, showing Grosse Mignonne, looking perfectly ripe. Mr. Williams, gardener to Earl Feversham, Duncombe Park, Helmsley, was second with Hales' Early; and Mr. W. Allsop third. For six Nectarines Mr. J. McIndoe was first with Lord Napier; Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, second; and Mr. J. P. Leadbetter third. For one scarlet fleshed Melon the first prize was not awarded; Mr. Jordan taking the second; and Mr. Keywood, gardener to W. H. Battie Wrightson, Esq., Casworth Park, Doncaster, the third. For a green fleshed Melon Mr. Jordan was first, and Mr. C. Lawton second. Mr. J. H. Goodacre won for a white fleshed Melon, Mr. J. McIndoe being second, and Mr. Keywood third. In the class for a dish of Cherries Messrs. J. McIndoe and Williams received the awards in the order named. For a dish of Strawberries Mr. Alderman was first; Mr. W. Chuck, gardener to H. Thelluson, Esq., Brodsworth Hall, Doncaster, second; both showing admirably. For twelve Tomatoes Mr. J. McIndoe was first, Mr. Keywood second, and Mr. W. Allsop third.

Several nurserymen added greatly to the interest of the show. Messrs. James Veitch & Sons, Ltd., Chelsea, arranged a grand display of Orchids, including *Lælio-Cattleyas* *Aphrodite alba*, *Canhamiana*, *Daphne superba*, *Wellesiana albidiana*, and *Hippolyta*, and *Lælia Digbyana*. Messrs. Charlesworth & Co., Bradford, had a fine group, in which were observed *Lælia cinna-brosa*, *Odontoglossum crispum magnificum*, *Cattleya Mossiæ Wagneri*, *Oncidium concolor*, *Cattleya Warneri*, *Oncidium crispum grandiflorum*, *Lælia purpurata Williamsi*, *Cattleya Mossiæ Reineckiana*, and *Lælio-Cattleya Lady Wigan*. Messrs. Laxton Bros., Bedford, had baskets of new Strawberries, Climax,

Fillbasket, and Mentmore. Messrs. R. Smith & Son, Worcester, contributed a group of miscellaneous plants, amongst which were some Clematis on balloon trellises, including Mrs. James Bateman, Beauty of Worcester, and Enchantress. Messrs. W. Cutbush & Son arranged a fine group with a background of Crimson Rambler Roses and Hydrangea paniculata grandiflora; the Malmaisons included Lady Ulrica, Thora, Lord Welby, Mrs. Trelawyn, Baldwin, Jane Seymour, and The Shah. Lady Ulrica is a splendid deep flesh pink. Cecelia, the Yellow Tree, and Duke of York were also fine. Messrs. Kelway & Son, Langport, had a group of Pæonies, including the Queen, Lady Curzon, and Portia. Pyrethrums and Delphiniums added to the display made by the Somerset firm. Messrs. Webb & Sons, Wordsley, Stourbridge, had a stand of tuberous-rooted Begonias and Gloxinias, with the new Pea Pioneer on a wire trellis. Messrs. Dicksons', Ltd., Chester, had a really fine display of English and Spanish Irises in great variety, with Heuchera sanguinea, Allium roseum, Aster alpinus roseus, Centaurea montana rubra, Campanula glomerata, Hesperis matronalis, fl.-pl., and the Ixiolirion tataricum, Achillea mongolica, and many beautiful Pyrethrums. Messrs. H. Low & Co., Bush Hill Park, contributed Orchids in their customary excellent style.—F. STREET.

Hardy Fruit Garden.

Summer Pruning.—The summer pinching or pruning of fruit trees is only carried out on trained wall trees, and those in the open restricted to a certain shape. If some means were not adopted to maintain them in the forms intended, and at the same time cause them to produce fruit, they would quickly go their own way, and then being cut back to the shapes desired would develop more and stronger growths, usually resulting in fruitlessness. By summer pinching the energies of the trees are concentrated in feeding a few buds instead of being wasted on a number of extension growths, which would eventually be removed.

Summer pruning may commence when the lower leaves of the young shoots are attaining their full size; the foliage is then able to do its full share of important work. Superfluous energy is worked off by the shortened shoots pushing their upper buds into growth, and these may be pinched to one leaf as made. As a rule summer pruning does not all require to be done at once, but is best carried out gradually. Commence with the vigorous parts of a tree, these usually being situated near the top. The weakest shoots are at the bottom, and they will take no harm if allowed to grow and strengthen a short time longer. The work may extend over a period of two or three weeks.

Gooseberries and Currants.—These ought first to have attention. Gooseberries trained in cordon form to walls, fences and wires, and not those in bush form, require the most attention. Red and White Currants, in whatever shape they are grown, need systematic summer pruning. The main branches are always cordons, and the summer growths, without exception, are closely spurred-in in winter. Summer pruning is very essential to make Red and White Currants profitable, as a thicket of shoots is in most cases made, and these must be shortened, so as to admit light and air—not only for developing the buds, but to assist the ripening and improve the flavour of the fruit. The bulk of the bunches are borne on the spurs, from among which the summer shoots spring. Gooseberries grow similarly. Shorten both these and Currants to three pairs of leaves. Remove altogether any weak or unnecessary shoots, and take out suckers and growths springing from the ground, and which tend to crowd bush Currants, unless they have clean stems a foot from the ground.

Apricots.—The shoots of Apricots that may be pinched and encouraged to form spurs are those for which no room can be found when laying in a stock of young summer shoots. Apricots bear as well on the latter as on spurs. The most convenient shoots for laying-in start from the side of the secondary branches. These, however, if not wanted are unsuitable to shorten for forming spurs. In that case entirely remove them. The foreright shoots, or those that grow straight out from the wall, are best for the latter purpose, but unsuitable to lay-in. With plenty of young wood spurs are not essential, hence avoid originating them to crowd the trees unnecessarily.

Plums and Cherries.—Plums and Sweet Cherries on walls, or grown in pyramidal or bush form, must have the summer shoots pinched to three or four leaves. In old trees vacancies may occur which require to be filled. In order to do this lay-in young shoots, giving them plenty of space. These will bear the second year. It is not desirable, as a rule, to crowd the trees with young wood.

Morello Cherries are treated differently, the method adopted with Apricots being suitable for them, though young shoots may be more freely laid in. Only a limited number of shoots should be shortened for spurs, and these ought to be well situated.

Apples and Pears.—These may be pruned the last, but in the majority of cases spread the operation over two or three weeks. The upper shoots of the trees grow strongly, while the lower are weakly. Very late summer pruning, or not pruning at all until winter, weakens all the lower spurs considerably, hence the importance of stopping strong shoots early wherever they are situated. In addition to this summer stopping barren or attenuated spurs can be removed from trees it is desired to improve, and some efforts made to reduce crowded shoots, especially in the centres of pyramids and bushes.

Strawberries.—*Watering and Feeding.*—Copious waterings as well as mulching are needed in light dry soils to bring the crop to maturity. Plenty of liquid manure may also be given during the time the berries are swelling, discontinuing when ripe. The drainings from stables and farmyards constitute the best food which can be applied.

Netting and Protecting Ripe Fruit.—As soon as the berries commence to colour birds find out the fruits and soon spoil the choicest. Fish netting should, therefore, be laid over the beds as a protection. Heavy trusses of fruit ought to be supported by forked sticks or some contrivance to raise them above the ground, especially if the surface of the mulching is not clean and dry.

Layering.—Where Strawberries are grown in pots for forcing it is an advantage to root some runners early. The plantlets with roots just showing may be secured on the surface of the soil filled firmly into 3-inch pots. Secure them in position with a hooked peg or a stone, partly plunge the pots in the soil, and keep regularly watered until established and then cut the runner wires.

Fruit Forcing.

Peaches and Nectarines.—*Early House.*—The fruit will shortly be all gathered, therefore admit all the air possible by day and by night. If the roof-lights of the earliest house are movable, take them off after the trees have had full ventilation for a fortnight, and keep the foliage free from insects by forcible syringings. If there be any red spider use a solution of softsoap 2 ozs. to a gallon of water; if scale be present employ paraffin oil, adding a wineglassful to 4 gallons of water, with which has been added 1 oz. of washing soda and 4 ozs. of softsoap. The soda and soap should be thoroughly dissolved in a quart of water by boiling, and the paraffin added whilst boiling hot, but removed from the fire, stirring briskly till amalgamated, then add the remainder of the water hot, and apply at a temperature of 130° to 135° with a fine rose syringe, or preferably a sprayer.

Keep the borders well watered, affording liquid manure to weakly trees, which helps them to plump the buds, and mulch with short manure. Cut away the wood that has borne fruit to the shoot at the base intended to bear fruit next season, unless the shoot is required for extension. If there be a superfluity of growths, remove them now; they only keep air and light from the principal foliage and hinder cleansing operations. Keep laterals and any good shoots closely stopped.

Houses with Fruit Ripening.—The trees must not be syringed, but moderate moisture should be maintained until the fruit is ripe. Water must also be given liberally at the roots. Admit air abundantly. In gathering Peaches great care is necessary, as the least pressure makes a mark and spoils their appearance. A piece of wadding should be held in the hand, and the fruit removed, then laid gently in a padded basket or tray. A cool and airy fruit room is the best place to keep Peaches and Nectarines in after they are gathered.

Trees Swelling their Crops.—When the stoning is over the trees will endure strong heat without fear of the fruit falling. Afford tepid liquid manure to the roots of trees carrying full crops, and otherwise not too vigorous. Be careful in giving liquid manure to very vigorous trees, as it tends to over-luxuriance, and may interfere with setting and stoning in the succeeding year. Still, liberal treatment is necessary, such as light surface mulchings and copious waterings every week or ten days in well drained borders. Syringe twice a day to keep down red spider; ventilate early, keep the temperature at 70° to 75° through the day, 80° to 85° with sun heat, and close sufficiently early to increase it to 90°. This, with abundance of moisture in the house, will insure large fruit, and if ventilation is given before nightfall and increased early in the morning all will be well; but if a close and moist atmosphere be maintained with high temperature, the fruit, though large, will lack flavour.

Keep the fruit with the apex to the light, laths across the trellis will admit of this being done, and clear away the leaves from the fruit, but do not remove them if it can be avoided. When approaching ripening cease syringing, admit air freely, and 60° to 65° at night will be a sufficiently high temperature or artificially in the daytime, unless it is wished to accelerate the ripening, when it should range from 70° to 75°, with a rise of 10° from sun heat.

Fruit Stoning.—Maintain a steady temperature of 60° to 65° at night, and 5° to 10° rise by day, with the usual advance of 5° to 10° or even 15° at closing time from sun heat. Avoid a close atmosphere, and maintain a uniform temperature, and as equable a condition of moisture as practicable. Sudden fluctuations of temperature and cold draughts are pernicious, and equally disastrous is insufficient water at the roots. Allow a moderate extension of growth during this trying time, and do not permit a great percentage of fruit to stone that must be removed afterwards, but remove it in good time. A superfluity of fruit at stoning prejudices the crop, and even if stoning takes place the fruit rarely finishes well, but is small and flavourless, and a partial failure another year may be anticipated. Stop gross shoots or remove them altogether, so as to maintain an equal diffusion of growth throughout each individual tree.

Late Houses.—Train the growths thinly, reserving a shoot at the base of the current bearing wood, and stop those on a level with or above the fruit at two or three leaves, and succeeding growths at a joint or two. Side shoots on extensions not required to form bearing shoots or for furnishing the trees stop at an inch or two of growth to form spurs, and by adding to the foliage will much encourage root action and benefit the fruit; besides, these spurs usually set fruit and swell it, when those on stronger growths do not. Thin the fruit to a few more than will be required for the crop, retaining the largest and best placed. There should not be more than one fruit to each square foot of trellis covered by the trees, but a few more may be left to meet casualties in stoning. Syringe twice daily on dull days. During the prevalence of dull weather an occasional syringing will be all that is necessary, as it does not answer to keep moisture hanging on the foliage—indeed, the leaves should be dry, or nearly so, before dark. Water inside borders fortnightly, and afford liquid manure to weakly trees. Mulch the borders lightly with short manure, and keep it moist; mulching dry ground is very little use.

THE BEE-KEEPER.

Supering.

No delay must take place in the supering of all stocks from which a surplus is to be obtained. The present season has shown the advantage of timely attention during the early spring months by encouraging the queen to continue breeding. The weather on the whole has been favourable, a couple of excessively hot days caused several swarms to come off. The casts or second swarms usually come about ten days after the swarm. They should be carefully attended to, as, being headed by young queens, they will make excellent stocks for another season. The bees should be encouraged to work in the supers by placing a section containing honey therein. Some fully drawn out combs will also assist them.

It is not necessary to allow the swarms to have access to the full number of frames in the brood chamber. Unless the swarms are early they will not fill a large hive with brood in time to be of use for the white clover. When bees are within reach of the Heather late in the season their treatment will be quite different. If the swarms are allowed not more than six frames in the brood nest, the division board is placed close up to them, and if the weather is favourable, the bees invariably take possession of a crate of sections provided. After the honey harvest is over the full number of frames is placed in the body of the hive.

Rearing Queens.

If the doubling system is practised for obtaining a surplus of run honey, there will be some stocks which are not up to their full strength. These are now utilised for queen rearing. Unless there is some system in maintaining a supply of young queens in the apiary success is not likely to follow. The old queens will succumb when they are most required; the plan we adopt and recommend has always proved successful. We usually select a strong colony from which to obtain our young queens. We first remove the existing queen, and notch in zigzag form the lower edge of a comb containing eggs laid during the past twenty-four hours. The same effect may be caused by boring holes through the combs. At each place the bees will start queen cells. If a sufficient number is not obtained, insert a frame of newly laid eggs from another colony, and more queen cells will be formed.

In this manner as many queens as may be required in the apiary will be obtained, and whilst they are maturing the weakened colonies will be increasing in strength, as the queens need not be removed till the last moment, when the queen cell may be introduced into each colony, as will be explained in future notes.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Spots on Grapes (E. T.).—The spots on the Grapes appear to be modified forms of scald. The cells immediately beneath and surrounding the damaged part of the berry are quite sound and not permeated by the mycelia of any fungus, but there is evidence of mycelial ramifications in the discoloured parts. The chief thing is to attend to the ventilation and admit a little air constantly. It is not likely to be caused by anything wrong at the roots, as that would affect all the Vines similarly, but is clearly due to some external cause, and appears to be from some direct injury, such as careless handling in trimming the Vines or in thinning the berries. It may also be due to moisture resting on the berries, and the atmosphere being heated by the sun before air was admitted.

Pears and Pear Leaves Diseased (W. R. O.).—The blackness on the three Pears is caused by the scab fungus (*Fusicladium dendriticum*, var. *pyri*). The preventive is to spray the trees thoroughly with dilute Bordeaux mixture just before the leaf buds open, repeating the application just before the blossoms open, for the third time after blossoms have fallen, and again ten days afterwards. The three Pears are eaten by some caterpillar, probably that of the winter moth (*Cheimatobia brumata*). For this pest add 1 oz. of Paris green paste to every 20 gallons of the dilute Bordeaux mixture, which will serve for all caterpillars and also those of the Codlin moth. The blistering on the leaves is caused by the Pear-leaf gall mite (*Phytoptus pyri*) which causes the leaves to become brown or black, greatly impeding the elaborating of the juices and weakening the trees. The best preventive is to spray the trees with petroleum emulsion, diluted with seven parts of hot water, when the trees are dormant, or just at the time they commence swelling the buds. The treatment must be thorough, choosing a dry time for the operation.

Tomatoes with Waxy Patches (Cross).—Various reasons have been assigned for the waxiness that occurs in Tomatoes and many other fruits. In effect it is a running together of the cells in certain parts of the fruit, and these portions became practically sealed against change in ripening. An analysis of the wax-like part differs little from the normal flesh in albuminoid and mineral substances, hence the analyses afford no clue to the cause. Still the wax-like portions contain much more cellulose, pectose, and sugar than the parts which remain normal in colour, but are deficient in malic acid, and this is very suggestive, especially in connection with your statement that bonemeal has been supplied liberally. This would favour the formation of the cellulose, pectose, and sugar; and possibly the practical closing of the cells may be due to a deficiency of potash. We have no recollection of advising you to supply bonemeal at planting, to dress with sulphate of iron as a remedy, or to apply lime this year, or to use liquid manure. Not any of these would, in our opinion, affect the fruit in the slightest degree, though the tendency to waxiness may be aggravated, as before stated, by the dressing of bone dust, and also of lime. We regard it as to some degree constitutional, and due quite as much to climatic conditions as to soil components. We cannot undertake analyses. Perhaps some of our readers may be able to throw light upon the subject, for we are convinced that only growers, by a mutual exchange of views and practices, can satisfactorily grapple with and overcome the defect which is greatly on the increase in this fruit.

Dipladenias not Flowering (Tyro).—The shoots of the Dipladenias should be trained close beneath the roof of your warmer house; in fact, they should do in either temperature, if fully exposed to the sun. If you do this, and give a good circulation of air daily during bright warm weather, we do not doubt that your plants will flower well. They do not flower satisfactorily if grown in shade and a close, confined atmosphere. Dipladenias require very careful watering, and although they can be well grown in pots, they do much better if convenience exists for planting them out.

Rust on Peaches (C. G. M.).—The fruits are "rusted" in places, also cracked in the oldest affected parts, and in others covered with the dense felt-like coat of *Sphaerotheca pannosa*, a mildew of frequent occurrence in this form on the Peach. The discoloured blotches are probably caused by wet lodging on the fruit. The affected fruits will crack more or less as they increase in size, and the best plan would be to remove and burn them. The disease, however, may be arrested by rubbing flowers of sulphur gently on the affected fruits, but it will not restore the epidermal tissues, and the fruits will be so cracked or furrowed as to be worthless for table.

Polypodiums from Spores (W. B. S.).—Polypodiums are readily raised from spores ("seed"). Take an ordinary flower pot or seed pan; drain well, and fill to within 2 inches of the rim with broken pots (corks). Put in 1½ inch thickness of soil, composed of peat and yellow loam in equal parts, with a third of corks broken small and a fourth of sharp sand. The rougher portion of the compost should be placed over the corks, and the finest at the top, which must be even and fine, the soil being pressed down firmly. Water thoroughly two or three times, and after the last watering scatter the spores—the powder-like dust on the under side of the fronds—on the surface. Cover the pot or pan with a pane of glass, resting it on the pot, leaving a space of about half an inch between the surface of the soil and the glass. Put in a shady place and keep moist. In a few weeks the sporelings will appear, and when they reach the glass remove it, or preferably raise it by pieces of wood. When the sporelings can be handled, pot singly.

Topping Oleanders (H. M.).—Oleanders may be cut back to any extent. They will break freely from the old wood, so that you may cut them down to within a few inches of the soil—say 6 to 9 inches—so as to secure a stem of a few inches length. Keep rather dry a short time before and after cutting down, and then water and syringe so as to encourage growth. Avoid, however, making the soil sodden by unnecessary waterings. If you cut the plants down they will not flower this year, and perhaps not next, as it must make and ripen good growth before doing so. We should put in cuttings of the strong growths in sandy soil; they root freely in gentle bottom heat, such as that of a Cucumber bed, and make very useful plants in 6 or 7-inch pots. Cuttings would also root in the conservatory if covered with a hand-light or bell-glass. Plants so raised would, no doubt, flower next year. The old plants could be kept through the year, and you will have the benefit of the flowers now showing. They require to be well supplied with water when swelling the buds and making growth, and kept rather dry in winter, but not so as to bring down the foliage. An occasional syringing is of benefit; avoid, however, wetting the flowers, as they are liable to damp.

Horticultural Exhibits and Railway Charges (W. H. J.).—As we had no really authoritative information on this subject, we communicated with the Great Eastern Railway Company, whose reply is as follows:—"In reply to your letter I beg to inform you that no alteration whatever has been made in our rates and arrangements for the conveyance of exhibits to and from horticultural shows. (a) Plants, fruit, or flowers, to or from flower and agricultural shows, are charged single owner's risk (or company's risk) rates for the double journey, providing they remain the property of the exhibitor. (b) Passengers travelling with plants and flowers are (on all occasions) allowed to carry as luggage or part of their luggage, the usual weight free, any excess being charged for at the excess luggage rate (owner's risk). When conveyed under the latter arrangement any excess has to be paid for both on the forward and return journeys. Exhibitors at horticultural shows have therefore the option of having their consignments charged at the ordinary trade rates as per clause (a), which are very low (in no case on this line exceeding 2s. 4d. per cwt.), and this insures free return in case the goods are unsold, or if travelling with them they can claim the usual allowance under clause (b), and in the event of any excess, pay for same at the excess luggage rate both going and returning." This will probably apply to all the English railway companies, but we cannot say definitely.

Names of Plants (Stirling).—*Rhodochiton volubile*. (C. P.).—1, *Geum coccineum*; 2, *Papaver nudicaule*; 3, *Centranthus ruber*. (F. J. L.).—1, *Viburnum plicatum*; 2, *Weigela amabilis*; 3, *Astrantia major*; 4, *Cercis siliquastrum*, the Judas Tree; 5, *Ornithogalum nutans*; 6, *Saxifraga rotundifolia*. (D. M.).—1, *Blechnum spicant*; 2, *Adiantum pubescens*; 3, *Aërides F'eldingi*. (E. J.).—*Solanum nigrum*. (Mac).—1, *Calycanthus floridus*; 2, *Tacsonia*, probably *Van-Volxemi*, good leaves ought to have been sent; 3, *Stapelia*, probably *normalis*; 4, *Phyllocactus* sp., flower decomposed on arrival. In Nos. 2, 3, and 4, good flowers and leaves ought to have been sent, as when several species are closely allied it is impossible to be absolutely certain with incomplete specimens.

The Agricultural Returns.

WE have been favoured with a copy of the above for 1899, and though 260 pages of statistics are too much to deal with closely, a few points of general interest may be found.

Greater confidence in the future of the Wheat trade may have accounted for the increase of 213,000 acres in the Wheat area of 1898, but if so the confidence must soon have been dispelled, for in 1899 there was a reduction of 101,225 acres, leaving the aggregate but little over 2,000,000. The lessened demand for Wheat straw and its low price may have been a factor in causing this diminution in the acreage. Barley and Oat straw always have their home value as fodder, but

we have known cases where an accumulation of Wheat straw was a nuisance, the farmers not being allowed to sell, so they burnt it. Barley gained three-fourths of the area lost by Wheat; Oats gained the remainder, as well as 17,000 acres lost by Rye. Peas are on the decrease, but Beans, after two years' comparative neglect, return to their normal acreage.

Potatoes do not vary much, but Turnips and Swedes once more show a loss—viz., 34,000 acres, the area having declined from over 1,500,000 acres in 1875 to 1,233,880 last season. Mangolds have increased 20,000 acres, and we are very glad of this, for we are convinced that many farmers have falsely founded prejudices against this most valuable crop, which deserves a much larger acreage. Cabbage also is not grown as largely as it should be, and we are glad to see an increase under the heading of Cabbage, Kohl Rabi, and Rape, and hope the first is chiefly responsible for it.

British horses are stationary in numbers, but cattle show a very satisfactory increase of 170,000. It is interesting to note that notwithstanding this, the non-breeding cattle over two years of age have decreased by 14,000, and the assumption may be made that British farmers are gradually being convinced that old bullocks do not pay them so well as they pay the butcher. There is a large increase in cows and heifers, and it is to be hoped that greater efforts will be made to retain the large sum of money the nation pays for imported milk—last year nearly £1,500,000, to say nothing of the butter, the imports of which reached the enormous sum of £17,250,000, being £3,000,000 more than in 1895.

A noticeable fact in connection with the butter imports is that France sent us £500,000 worth less butter in 1899 than in 1895, whilst Denmark sent us $1\frac{1}{2}$ millions worth more, other countries showing a large advance being Holland, the United States, and Canada, the progress of the latter being most remarkable, for she sent us seven times as much butter in 1899 as in 1895, and the increase is steady as well as persistent. It is quite evident that the British butter produce has not yet seen the worst of foreign competition and attention must be chiefly directed to producing the very best article, so that he may not have to take 7d. and 8d. per lb., as many farmers' wives are doing now, whilst foreign made stuff is selling at 1s. in their own market town.

Very interesting tables are those giving the number of fat animals and quantities of dead meat sold in the London markets during the last twenty years. British fat cattle have decreased from 200,000 in 1879 to 86,000 in 1899, whilst foreign have increased from 126,000 to 168,000. British sheep have dwindled from 807,000 to 546,000, whilst foreign have gone down from 1,556,000 to 844,000. Taking British and foreign together we find a large diminution both in live cattle and sheep. How has London been fed? The dead meat statistics answer that question. The quantities for 1899 are almost double those for 1879, being 8,109,000 cwt. and 4,272,000 cwts. respectively. This increase of 4,000,000 cwts. is equivalent to 300,000 cattle and 3,000,000 sheep. Accepting the latter figures as being about correct, and adding together the supplies live and dead, we find that the dead meat has made up the deficiency in the live animals and increased the general supply by quantities equivalent to 220,000 cattle and 2,000,000 sheep. It is obvious that the consumption of meat has much increased, as prices have come more within reach of the working classes, and that the imports of chilled and frozen meat are likely to increase, for of the increase of 4,000,000 cwts. of dead meat imports 3,000,000 are accounted for by American and Australian killed meat, *i.e.*, chilled or frozen.

If we look at the statistics of foreign flocks and herds we find that Australasia owns 12 million cattle and 100 million sheep, whilst the two South American States, Argentina and Uruguay, own between them 26 million cattle and 90 million sheep. Here are almost unlimited possibilities for extension of the frozen meat trade, and the price of second-class meat must, at any rate in our time, be kept down to a low figure by the competition from these countries. All this points yet again and more strongly to the breeding of animals with a view to the butcher's requirements to meet the first-class trade, for it

is such stock which are now very dear and likely to remain so. Supplies of the best British meat must get proportionately smaller as the population increases.

It is also very unlikely that this trade will be affected by Continental competition, for the statistics of live animals belonging to our Continental neighbours show diminutions which may be considered quite alarming, and should be so to the authorities of those countries. For whilst Great Britain has not only fully maintained her flocks and herds but increased them, how can we account for the following figures? Austria and Hungary together have increased their cattle from $12\frac{1}{2}$ millions to 15 millions, but their sheep have fallen from 20 millions to 11 millions. France is stationary as regards cattle, but has lost $1\frac{1}{2}$ million sheep. Germany has increased her cattle by $2\frac{1}{2}$ millions, but has reduced her flock of sheep from 25 millions to something under 11 millions. The smaller countries, Holland, Belgium, and Denmark, tell much the same tale, and the lesson the farmer may learn if he will is, that however the trade for good fresh beef may fluctuate, he has the trade for the best home killed mutton in his own hands.

One table which rather took our fancy is one giving the average prices of the various kinds of grain sold in each of the principal markets during 1899. At the first glance the comparison of prices between one market and another promised to be interesting, but really only bears out what should be foregone conclusions—viz., that Wheat is dearest near the great centres of population, but does not vary much, whilst that Barley on big exchanges is much affected by the proportion of grinding qualities and makes the highest price in the neighbourhood of large maltings. Probably the good quality of the Barley induced the building of maltkilns.

A feature of the returns is the exceedingly bad Turnip crop of 1899, but we have all seen enough of that, and it needs no further discussion.

Work on the Home Farm.

The tropical weather of the past few days is doing an immense amount of good, and will give a very much needed fillip to many backward crops. More rain, however, is needed, the thunderstorms have been very partial, and a good general rain coming at once would improve prospects more than anything.

Wheat is running fast towards the ear, but few heads will be visible until July. Barley is improving in colour and is growing well, but some fields will be short in the straw unless we get the rain.

Mangold are much improved; weeds, however, have been troublesome, and although the young Mangold are rather small for singling, they will be best hoed at once so as to get rid of the weeds. There should be little more trouble now with the Turnip fly, for small Turnips love hot weather, and Swedes will soon be ready for hoeing. The main crop of common Turnips are going into a perfect hotbed, and must do well. We think this year's Turnip crop must be secure.

The horse hoe must be made use of whenever possible, leaving as little work for the hand hoe as can be managed. Some farmers, as we have mentioned in a previous article, run a set of harrows across the Turnip rows when labour is not available, thus thinning the plants until men can be found to finish the process. A horse hoe for corn crops is also sometimes useful to run across Turnip rows, but it requires careful manipulation, being somewhat drastic in its effects. It acts better amongst Turnips grown on the flat than amongst those on ridges. The plant also must be a very good one—*i.e.*, very even and regular, but not too thick. Field Potatoes look very well, and the earthing plough is at work in some cases for the second time. The land is rather dry between the ridges, having been knocked about a good deal, and is much inclined to fall back into the furrow. A nice rain would do good here.

Buyers of wool are hovering round, and though they cry down the prospects of the trade we fancy prices will be a little higher than they have been recently. Prices of wool often vary much in the same place, the stapler bidding freely for a good clip, and badly for one in which he expects, from old experience, to find much dirt and badly washed wool. We still think the man who washes his sheep well gets paid the best in the long run.

Live Stock Feeding in Yorkshire.—The authorities of the Yorkshire College, Leeds, in conjunction with the East and West Ridings Joint Agricultural Council, have issued a report on the pig-feeding experiments made at Garforth. They conclude that a mixture of barleymeal and sharps is better than barleymeal and maize, and that the latter mixture may be somewhat improved by the addition of a highly nitrogenous meal. A report has also been issued on cod liver oil as a substitute for cream and for meal in calf rearing.—(“Yorkshire Post.”)

 With full directions for planting in the best way most likely
 to ensure success.

5/-, 7/6 & 10/6 per doz. 38/-, 55/- & 75/- per 100.
 Half quantities at half rates, but less than half dozen will
 be charged 1/- each, and sent post free.

"Trails of any length up to 40 feet, a mass of glowing
 SCARLET FLOWERS succeeded by lovely BLUE BERRIES this
 plant gives when it does well."

X CLIBRANS', ALTRINCHAM X

"West's Plant Grip Stakes."

Everlasting double grip Stakes for
 instantly staking all plants. Send post
 card for Illustrated Catalogue.

**"WEST'S Patent VAPORISING
 FUMIGATOR."**—Best and Cheapest, for
 being made of brass and zinc, will last for
 years. The stove only requires a little
 spirits to saturate the asbestos, so may
 be used thousands of times without wick
 or further trouble. Price complete with
 Stove and Bottle of Spirits, 9d., post
 free, to vaporise up to 2500 cubic feet.

**"WEST'S EXTRACT OF NICO-
 TINE"** is guaranteed pure Nicotine,
 and three times as good as the best
 compound. It is not a compound, i.e.,
 not a chemical substitute for Nicotine,
 but will make a compound equal to the
 best if desired at 2½d. per 1000 cubic
 feet. Price 7d. per Sealed Bottle of
 1000 cubic feet, post free.

"WEST'S INSECTICIDE" can be proved to
 be the Best and Cheapest by sending for a free sample box.

"WEST'S POWDER WEED KILLER."—Best and
 cheapest. Guaranteed satisfaction. 1/6 tins post free.

For particulars of West's Patent "Ivory" Plant Labels,
 Soft Metal Tree Fasteners, S. M. Plant Clips, Gardener's
 Fountain Pen, Powder Diffuser (for dusting powder on
 plants), Wall Nails, Flower Grip Holders, Plant Pot Cocks,
 West's Fertiliser, West's Lawn Sand, West's Mealy Bug
 Destroyer, &c.; see Illustrated Catalogue of West's Patent
 Garden Specialities, post free. Samples free, postage extra.
 All goods made on the premises of C. E. West, and delivered free.

"Orchid Culture," 3rd Edition, postage 3d.; gives
 full particulars of the cultivation of Orchids.

Journal of Horticulture.

THURSDAY, JUNE 28, 1900.

The *Journal of Horticulture* can be obtained
 from the Office, 12, Mitre Court Chambers, Fleet St.,
 London, post free for a Quarter, 3/9. Editorial
 communications must be addressed to 12, Mitre
 Court Chambers, Fleet Street, London.

The Changes of Horticulture.

I CANNOT claim to be an ancient
 sage who has marked the changes
 and progress of horticulture during
 a long roll of years, and thus
 gathered wisdom at each step, but

to me everything in life is judged by
 comparison, and I find great interest in
 watching the "signs of the times," noting
 the direction in which they trend, and
 comparing them with memories of twenty years
 ago. The point in connection with both horti-
 culture and agriculture which at the present time
 strikes me most, is the dearth of well-grounded,
 painstaking recruits. True, we have schools of
 horticulture, and even lady gardeners, but I fear
 that the majority of recruits who are trained
 in such schools look upon a theoretical knowledge
 as a substitute for rather than an adjunct to the
 hard work and continuous efforts by which alone
 real gardeners are made.

The value of a scientific training is undoubtedly
 great in moulding the mind to those habits of
 close observation and systematic research which
 in after life should form the stepping stones to
 successful management when responsible posts
 have been attained. All probationers ought, how-
 ever, to remember that the reward for theoretic
 knowledge will not come in the early stages of
 their career; it should rather be regarded as so
 much "capital" invested for interest in the future.
 Neither will it ever be a substitute for thorough
 practical knowledge and capacity for work, both
 of which are indispensable in carrying out a
 successful career.

Given two men with equal talents and oppor-
 tunities, the one who possesses both practical and
 scientific knowledge is generally more likely to
 attain distinction than the other, who, however
 good in practice, has neglected the scientific part.
 I write "generally" because there is another
 element which plays a potent part in moulding
 careers in these days of keen competition, i.e.,
 continuous effort—energy; without it no lasting
 success can be achieved, and this explains the fact

that the "plodder" with perhaps few natural talents frequently out-distances his fellows who rise above him in real ability, which they turn to little account, simply because they lack energy or possess it only in a spasmodic sense, and are therefore wanting in stamina.

But what about "the lady gardener?" some may ask. Is she destined to become a real and serious force in the horticulture of the future? I think not. Let us admit that those who conceived the idea of founding establishments for the training of lady gardeners were actuated by the best of motives in opening up new fields of employment—new spheres of influence—for the gentler sex, yet I think there are few practical horticulturists who have much faith in the movement. They hold that women as a rule are physically unfit to accomplish the laborious work which it is necessary for them to undergo in order to become well trained gardeners. I will go still further and say that 99 per cent. of those who have intelligence and ambition enough to aspire to become the gardener-in-chief in some extensive establishment have not the inclination to undergo the necessary drudgery, or if they possessed the inclination for a time it would disappear before their object was attained. The desire to secure a post which to many seems an ideal one may be strong in hosts of women, but between the wish and the accomplishment thereof arises a mountain of difficulties which not more than 1 per cent. can hope to surmount. In the lighter tasks of horticulture connected with the businesses of florists, there is a great and remunerative sphere of work open to women, work which is in every way suitable for them, and for the performance of which they have intuitive talent, but as real all-round gardeners the ladies are a failure, unless their object is to qualify for becoming the wives of mere men gardeners. As a matter of fact many gardeners' wives have a fund of horticultural knowledge, that many a college-trained lady gardener would envy did she but suspect its existence.

Gardening for pleasure is a delightful pastime for any lady, but it is a totally different matter to enter upon the work with the object of getting a living at it, and I fear that many have already been induced to take up gardening as a serious business of life only to meet with bitter disappointment, as they gradually find out that in the occupation which looks so pleasant upon the surface there is such constant laborious work to be done and so much dogged perseverance needed. Youths do not now take to gardening as a calling so readily as formerly, because they find so many opportunities of starting in other occupations which offer better prospects and less drudgery in the early stages. Is it therefore likely that women will be long in finding this out? I think not; the lady gardener has not come to stay, but will change her calling as quickly as the fashions change. There are, one must admit, advantages to be found for women in gardens, but these lie rather in the health-giving fresh air of some of the work than in the avocation as a means of livelihood.

There is, however, a great problem in connection with both horticulture and agriculture which will have to be dealt with before long, as the depopulation of villages and great scarcity of labour during the summer months are more apparent each year. This problem, in my opinion, will only be solved by the importation of foreign labour. Education has done, and is doing, a great work in fitting the British for the parts they are to play in the progress of the world. With a splendid world-wide empire which is daily becoming more solidified, there will be a growing demand for men with energy and brains in all parts to act as the guiding spirits in horticultural undertakings where native labour is abundant; and those who shirk no task during the training they receive in their early days—and thus make themselves proficient in both science and practice—will meet with their reward. They will also help to uphold the supremacy of the Empire in distant lands, while to perform the menial work in Britain, Kaffirs, Chinamen, and perhaps Japs, will be imported. This seems to me to be a gradual process of evolution which education is working in the British race. In time it will bring prosperity by leaps and bounds, and when that time comes the great problem as to "spheres of influence" for women will solve itself—there will be no necessity for them to compete with men in the labour markets of the world.—ONWARD.

Bouquets of Wild Flowers.

IT was a matter of common observation that wild flowers proved scarce during the summer of 1899 in many parts of Kent, and probably elsewhere also. Familiar species of the fields, hedgerows, and woods which had struggled into bloom speedily disappeared, and others, which are usually abundant, never flowered. This we assume was to be attributed to the dryness of the year, both spring and summer being very deficient in rainfall, while the intense heat of the sun dried up many plants, even to the roots. We had plentiful rains in the early months of 1900, and though April was a little dry, if we get some pleasant showers during June it is likely we shall have soon a good display of wild flowers generally.

This is of interest to large numbers who live far away from the country, as it is one of the philanthropic agencies of our day, forwarding newly gathered wild flowers to hospitals, workhouses, schools, and sick persons in towns, the occupation of collecting and packing affording agreeable employment to those having the opportunity, with spare time. Unfortunately, it sometimes happens that bouquets or parcels of flowers arrive in a condition which is disappointing to the receivers; possibly the weather may be blameable, or the postal authorities, but often the cause is injudicious picking and packing. For one thing, with the majority of wild species, it is no use to send fully expanded flowers; they dry or fall to pieces. Sprigs and stems, severed by a pull, will fade more rapidly than if cut off with a knife or scissors. Nor is it advisable when that can be avoided to gather flowers which are to travel during the heat of a summer's day; it is better to take them in the cool of early morning or evening. We frequently see children carrying bunches of wild flowers in their warm hands, they are seldom worth keeping if taken far exposed to the air. Should they not be enclosed *pro tem.* in a tin box or case, like the botanist's *vasculum*, they may be laid in a basket of some kind, where they can retain any moisture there is about them, and even in a bag of cloth or leather they will not be injured, only a mixed gathering of plants, tough and tender, must not be pressed closely together in transit.

Some people say that if wild plants are lifted by the roots and then sent away, they keep fresher than do portions cut off; but it is not always convenient to remove them thus, and except in the case of very common species it is scarcely advisable to carry them from their habitats bodily. It is this digging up of specimens which has almost denuded many woods of Primroses and Violets, though it has enriched gardens for a time. Again, some persons think that when wild flowers have had an hour's journey or more, before they are brought indoors they should be freshened up by putting the stalks in water before they are packed to send away. "Wood Anemones," remarks Miss Jekyll, "protest against being picked, and come home limp, closed, and looking very unhappy; all the same they will recover if they have a bath for an hour or two." Certain delicate Umbellifers suffer, and rosaceous species, too, unless carefully dealt with, but we have sturdy wildlings which do not mind rough treatment. Then there are some wild flowers that appear averse to living in water even for a brief period, in spite of such expedients as putting fragments of charcoal in, or adding a little ammonia and other contrivances for vitalising them. The lady above named also tells us that sprigs or branches taken from hardwooded trees and shrubs should have the cut end sliced up one side, or cut through the middle, which enables the water to enter more readily. She has even found it serviceable to give an end of a twig a smart blow with a heavy hammer.

When it comes to packing wild flowers to travel by post or rail, I think, while all crushing should be avoided, it is desirable to put them together closely. Nor do they require air while travelling. A loose arrangement in packing causes a vibration, or perhaps abrasions, which are damaging to many flowers. Tin boxes might be considered preferable, though some prefer a light wood to these, because the tin is more affected by the sun or other heat if the package should

be exposed to an advanced temperature in travelling. Gardeners frequently use wet cotton wool for packing flowers and fruit. I am partial to it myself. If one has time and patience it is well to place a little damp moss about the ends of the plants or flowers, and some dry moss above to prevent shaking. The leaves of Monk's Rhubarb (*Rumex alpinus*) are capital for a wrap, keeping the flowers cool, and warding off pressure. It is decidedly objectionable to make the plants very moist, as in summer decomposition may set in before the journey's end. Small parcels of plants will travel all right if fastened in corrugated paper without any box.

When released at their destination stems and twigs should be cut again at the ends before they are put into water, nor is it good to

FIG. 147.—ODONTOGLOSSUM ROLFE, WALTON GRANGE VARIETY.

supply them with that which is drawn from a cistern where it is cold. Water just tepid is preferable, and this should be renewed daily, also removing any dead portions of the plants. In this way I have seen wild flowers kept fresh for a week or more, but of course they should not be exposed to the sun or a glare of artificial light.—J. R. S. C.

Odontoglossum Rolfe, Walton Grange variety.

ONE of the most beautiful Orchids at the meeting of the Royal Horticultural Society held in the Drill Hall on June 19th was *Odontoglossum Rolfe*, Walton Grange variety, of which a flower is admirably portrayed in fig. 147. The plant was shown by Mr. W. Stevens, gardener to Wm. Thompson, Esq., Walton Grange, Stone, Staffs, and the Orchid Committee recommended a first-class certificate. It is a hybrid from *O. Harryanum* and *O. Pescatorei*, and traces of both parents are clearly discernible. Both the sepals and petals are very broad, and have the most profuse brown markings; the ground colour of the former is pale rose, this shade also prevailing at the tips of the latter. The lip is broad and flattened, the front lobe being white and the basal portion brown and crimson.

The Royal Horticultural Society.

The Proposed Bye-Laws.

A VERY urgent appeal has been made to me in my official capacity as Secretary of the R.H.S. by certain of the Fellows who are most anxious to show their loyalty to the Council by supporting them in their proposals with regard to the bye-laws of the Society, but are unable to do so entirely so long as Nos. 45, 46, 47 are retained. They have no objection whatever—many of them cordially approve of—the Swiss principle of a referendum, "Aye" or "Nay," on any important proposal, but they dislike a general proxy.

At this late date I have no time or authority to call the Council together to consider this point. I am therefore writing quite unofficially to say that I am confident that the Council will accept a permissive referendum on points they think to be vital to the Society's welfare. The Council, I am convinced, have no desire for a general proxy, but they feel, and feel very strongly, that as the Society has recently been increased by such an enormous accession of Fellows living at a great distance from London, it is unjust to confine the whole governing power of the Society to Fellows living in or near London, which would practically be the case if no referendum on important points is permitted.

The Council would, I am sure, accept the three following bye-laws in the place of the three whose numbers they bear, together with the form for a referendum which I have drafted.

I have written this letter solely in order that Fellows may have time to consider the matter, and to induce country Fellows to come up to the meeting of July 3rd and support a measure for their own enfranchisement.—W. WILKS, *Shirley Vicarage, Croydon, June 25th, 1900.*

Alternative Bye-Laws.

- 45.—With respect to any resolution brought before a general meeting, and considered by the Council to be of vital importance to the welfare of the Society, the Council shall have power to adjourn the meeting for not more than twenty-eight days, in order to refer the decision on such resolution to the whole body of the Fellows, and to take a poll of the Fellows "for" or "against" it.
- 46.—In the event of any resolution being referred for decision from a general meeting to the whole body of Fellows, the Council shall within ten days after such meeting issue by post to every Fellow of the Society residing in the United Kingdom a copy of the resolution thus referred, together with the necessary form (Form D) for voting for or against it. But the Council shall not therewith or otherwise at the expense of the Society send any communication tending to influence the vote of the Fellows.
- 47.—When any resolution is referred from a general meeting to the whole body of Fellows for decision the general meeting shall, before it adjourn, be requested by the chairman to nominate four scrutineers of the poll, whose duty shall be to examine and classify the votes of the Fellows, and report the result to the adjourned general meeting. Two of the scrutineers shall be chosen from amongst the members of the Council, and two shall be Fellows holding no official position in the Society. In a poll every Fellow shall have one vote, and one only.

Form D.

Form to be used in event of the Council considering any resolution submitted to a General Meeting to be of sufficient importance to require a poll of the Fellows to be taken to decide it.

At a General Meeting of Society, held on [date] the following resolution was proposed and seconded—viz., [here insert the resolution.]

The Council considering this a matter of vital importance to the welfare of the Society, and acting under Bye-Laws 45, 46, 47, adjourned the meeting till [hour], on [date], at [place] in order that meanwhile a poll of the Fellows may be taken.

You are requested to sign your name in one or other of the two blank spaces below, and to return this paper entire to The Scrutineers, R.H.S. Office.

I desire to vote FOR the above resolution.	I desire to vote AGAINST the above resolution.
Fellow's } Signature }	Fellow's } Signature }

This paper is issued by order of the Council, and is sent by post to every Fellow residing in the United Kingdom.

.....
Secretary.

N.B.—Nothing is to be written on this paper but the Fellow's signature.

Summer Treatment of Roses.

THE successful cultivation of Roses by whatever method they are grown is largely governed by correct treatment in summer. On light, dry, hot soils mulching is necessary in order to prevent the rapid escape from the surface of the limited amount of moisture. Additional supplies of liquid food must also be given as sustenance for the roots, much of the available moisture present in the ground during the earlier part of the year being either appropriated by the roots or draining away in the subsoil. This is especially the case with old Roses, which being of large size and having a strong system of roots make heavy demands upon the nutriment available. With an unlimited rooting medium they can and do find what they require, but Roses are frequently grown where they have not this advantage, hence a deficiency arises if the supply of moisture is not duly maintained.

The results accruing from this make a decided mark upon the future success of the plants, if not upon their present condition in lessening the vigour of the display of bloom. If the failure of support occurred soon enough in the season, it would affect the blooming to a large extent, as at that time support generous, unflinching, and regular is needed for the full development of the blooms, and imparting to them depth and richness of colouring. An adequate supply of moisture not only benefits the blooms, but assists the healthy and vigorous production of new growths. Much of the unsatisfactory progress made by Roses is due to dryness in the soil. Something may be due to poverty of soil, but a dry soil, however good, cannot help being poor during the time it remains in a dry condition.

Health and vigour are the great antidotes to insect pests and fungoid attacks. These evils can only make headway when plants are at a standstill as regards summer growth. A temporary cessation of progress may cause an attack of aphids, but permanent checks induce troubles which are more lasting in their effects. Mildew is perhaps one of the greatest foes to Roses, because when it takes possession it is difficult to completely eradicate it. The best remedies are sulphur for the leaves, and moisture and food for the roots.

Frequent syringing of the foliage during the warm weather is undoubtedly a great advantage for Roses on walls and other positions where rain and dew do not easily reach the foliage. Clear water is all that is necessary when there are no insects present, but soapy water or soapsuds will prove efficacious if green fly, which attacks the points of young shoots, or the yellow fly, which commits so much havoc on the under sides of the leaves, happen to be present.

The summer pruning of Roses is not generally necessary, though gross shoots and weakly spray may be removed with advantage. Banksian Roses should be pruned after flowering, cutting out shoots of a gross character and removing the tips of those retained. Mosses, Provence, Austrian, and Penzance Briars require the old shoots removed in summer after they have bloomed. Dead, decaying, and exhausted wood is best removed whenever it is noticed. Immediately flowers fade pick them off the plants. As the growth of climbers advances secure it to the wall or the training space to be filled. This gives an opportunity to properly fill the area without crowding and insures the thorough ripening of the wood.—E. D. S.

Hardy Flower Notes.

WITH June there comes a greater richness of beauty than the earlier months can give, though the beauty can be of no higher order than that of the winning days of spring. With the early days of the month the outdoor Roses generally appear. The grand Roses which are so fine on the show board have no want of supporters in the columns of the Journal; and, besides, not one of these had opened at the time of writing. A Monthly or two have appeared, but they are so accommodating and so floriferous that one never wonders to see their blooms, whether they come at midsummer or in midwinter. It is not so, however, with the Rose species, some of which have begun to appear. There are a few beautiful blooms on *Rosa rugosa*. Fine also is the Rose known as *altaica*. A few days ago I saw a great bush of *Rosa sericea* with a host of beautiful single creamy white flowers. The little buttons of the double yellow Scotch Rose will open in a day or two. They will soon be accompanied by the others of the family, whose flowers have inspired many songs and tales.

Shrubs and trees, large and small, are also full of glorious or of quiet loveliness. Laburnums and pink and scarlet Thorns are to the garden what the common Hawthorn is to the field. Full of beauty are they. One naturally turns, however, to the things which are less seldom seen. *Cytisus scoparius* Andreanus has found its way into favour more rapidly, perhaps, than any shrub of recent introduction. Very beautiful is a huge bush of it when covered with its brown and golden flowers. By the rustic stone steps in the garden is a fountain of the white Portugal Broom, than which nothing looks finer against its background of fresh green Ivy. Prized because of the pleasing variegation of white and green in its foliage is *Cytisus scoparius* variegatus. It must be said, however, that this colouring takes from the effect of the golden flowers which always show so well in contrast with the deep green of the typical plant. Then there are the varieties of *Cytisus purpureus* with their varied shades of purple, none being prettier than *C. purpureus incarnatus*. But one must turn to other things.

There is nothing in the garden at the present time finer than the German Irises with their marvellous colouring. They are so numerous in their varieties, and all are so beautiful, that one can hardly pick out a few and say "these are the best." The new Irises will gradually come into the market, but no one need wait for them, for the older varieties are beautiful enough to give pleasure with their charming flowers and that wonderful colouring, which defies description, and strikes one with increasing admiration as the flowers are studied with keenest scrutiny. These German or Bearded Irises are never so happy as in a place where they can be roasted in summer and have full exposure to the sun at all times. Six inches of soil on a wall or roof will grow them well provided they are "anchored" by having stones placed on the rhizomes.

The glory of some gardens now, and the pride of their owners, lie in the spikes of a few of the Eremuri, whose fortunes in our gardens the writer has followed with much interest. They have been seen where their magnificence was indisputable; they have, alas! been seen and heard of in gardens where disappointed owners could only lament their inability to grow them so as to persuade them to flower. There is no infallible treatment which can be advised. One thinks and proves that they will grow best with him in a semi-shaded position, while another finds they do best in full sun. One advocates deep soil, and another can grow them well on a hard bottom with only 6 inches of loam and manure—3 inches above and 3 below the roots. So noble are the Eremuri that one will do well to persevere with them, even if success should not at first reward one's efforts.

The Pink is likely to remain a favourite flower, though the laced varieties of the florists are at present under a cloud, awaiting, perhaps, the time when the artisan who succeeded the hand-loom weaver will wend his way to the outskirts of our overcrowded cities, and find health and pleasure in growing flowers as did his predecessor in pre-factory days. The border varieties do not lack favour, though, and none are greater favourites than the deliciously scented white Pinks. One which I recently saw was named Bradwell White; it is a fine flower, large, and of great beauty and perfume. One of its highest merits is also its grand healthy growth and the sturdy upright stems on which its flowers are produced.

One's pen could run on in telling of flowers as they appear, and of the host now in bloom. The delightful little *Helianthemums* or Sun Roses, and the *Cistus* or Rock Roses open to the morning light, and when dull days prevail last longer than in the brighter hours. The Candytufts have not yet left us, while the tall Lupins rise above their lowlier brethren just as some sacred fane towers far above the less stately dwellings around. Columbines of many hues, and with long and short spurs, dangle from their stalks, though many flowers have passed away and are now followed by their horned seed pods. Then what can one say of the Poppies without incurring the wrath of those who despise their "flaunting" cups? I saw, a while ago, some plants of *Papaver ruporient*, the hybrid from *P. rupifragum* and *P. orientale*. A charming plant is this, surpassing the other hybrids I have from the same parents. Thus might one run on telling of the flowers; but, were it not that they are too many.—S. ARNOTT.

Notes on Rhododendrons.

AMONGST hardy evergreen shrubs Rhododendrons must be accorded the most honourable position in gardens. When in full beauty they are unsurpassed by any flowering evergreen, and when out of flower their shapeliness and bright green foliage render them fitting specimens for the lawn or for massing in beds. They are at home in any position, whether in the neighbourhood of a town or the pure air of the country; under trees, or in the open; in sheltered nooks, or in exposed situations; they are alike suitable, and thrive if their simple requirements are attended to. They, however, do not like soils in which lime and chalk prevail, and in such instances special preparations must be made for them. They are worthy of all this, and of much more care than is bestowed upon them in many gardens.

Rhododendrons will grow under forest trees, but should be planted at the same time, for after trees become large and the soil crammed with roots there is great difficulty in establishing them. Before they have a chance to take possession of the soil by their roots they suffer from drought, and often die the first season after planting. If the large growing trees have been well thinned, and proper stations are prepared by digging as deeply as the soil will allow, incorporating with it leaf mould, manure, loam, or even the refuse of the potting shed, or a quantity of the whole mixture together before planting, success can be insured, especially if the shrubs are well watered for the first season until they have taken possession of the soil. In the front of plantations of forest trees there is less difficulty in establishing them. When once established in woods or plantations in which the leaves of the deciduous trees are allowed to remain they will need little care. When both are planted together and the trees duly thinned they grow rapidly if the soil is of a fertile nature or rendered so by preparation. For undergrowth, as well as for the margins of woodland walks and drives, no other plant equals *R. ponticum*.

In whatever position they may be planted, it is a great mistake to prepare only a small hole and render the soil just surrounding the roots fertile to give them a start. Under this treatment the shrubs grow well for a few years until the prepared soil fails to supply them with the requisite amount of food. They then decrease in health and vigour in proportion as the soil beyond the station made for them is rich or poor. In naturally fertile soils they flourish without farther trouble, but in the majority they become thin and bare, while in others they linger between life and death, only to succumb the first time their energies are severely tested by a long spell of drought, cutting winds, or severe frost. They frequently succeed better in woods when left to Nature for their supply of food than they do in borders and dressed portions of the pleasure grounds. It is in these positions that Rhododendrons, instead of growing luxuriantly, become bare from exhaustion. Every particle of material that would supply them with food is brushed away for the sake of appearance. This I should not object to if the shrubs were supplied with food to sustain them in health and fit them to withstand the adverse circumstances to which they are often subjected.

I have seen these shrubs grow with wonderful vigour in 6 inches depth of heavy soil resting on a bed of clay, and equally well in light sandy loams, also on peaty soils when left to nature. In each instance, as is natural to the Rhododendron, they root nearly on the surface, and their own leaves and those that are drifted under them soon produce a mass of fibres, and the fallen leaves also protect their fine silk-like roots from destruction by drought. In gardens their food is removed, and annually numbers of the surface roots are cut off by the too general practice of digging amongst them. In summer they suffer by drought, and with such treatment well may they be poor, thin, and unsightly.

Planting in exposed positions should be done during the month of September. In sheltered positions Rhododendrons can be planted at almost any season of the year provided the soil is moist; if not, considerable labour is occasioned in watering. Digging should never be practised about the roots; it is only done to give a neat appearance, and prevent leaves that have drifted from being blown out and carried on to the lawn. This is to save labour, which can be accomplished by another method, if not perhaps quite so quickly, with benefit to the shrubs. The loose leaves can be brushed out or drawn out with a rake unless the necessary material is at hand for top-dressing them as the work of cleaning proceeds. Refuse from the garden, such as leaves, the mowings of lawns, and the edgings of walks, make capital material

for top-dressing. The refuse from the potting shed, the surface soil removed from vineries and Peach houses—in fact all soils after they are useless for indoor work—are excellent for this purpose. Often old hotheds are available, and a few loads of soil after the most fibry portion has been removed for potting and other purposes, can be purchased in the neighbourhood of towns for covering leaves or material that might blow about. In some gardens the quantity of refuse from the various departments amounts to a large heap in twelve months, which if thrown together and turned will be found to be ample for top-dressing many clumps and single specimens of Rhododendrons. They root freely into leaves or garden refuse, which generally consist of a quantity of rich fertilising material. On light soils I prefer a dressing of cow manure with a thin sprinkling of soil on the surface, because it retains moisture much longer than a dressing of refuse.—A. N.

Rhododendron Pink Pearl.

When we take into consideration the fact that only one plant received a first-class certificate at the meeting of the Royal Horticultural Society on June 5th, we may safely conclude that it was of exceptional merit. This is certainly true of *Rhododendron Pink Pearl* (fig. 150, page 553), which is one of the finest hardy Rhododendrons we have. It has been previously exhibited, and has received an award of merit, but on this occasion, when it was

shown by Mr. W. Bain, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, the higher honour was recommended. Wherever it is seen it receives unstinted admiration. The trusses are of the largest size, as are the individual flowers; while the colour is particularly pleasing. It is distinct from all its relatives, and ought to be found in every garden where these superb evergreen shrubs are appreciated.

FIG. 148.—*NYMPHÆA STELLATA*.

Nymphaea stellata.

CONSIDERING the great beauty of several of the choicer Water Lilies it is a matter for constant surprise to many persons that they are not more generally grown. The extraordinary exhibit of *Nymphaeas* arranged by Mr. Jas. Hudson, V.M.H., gardener to Leopold de Rothschild, Esq., Gunnersbury House, Acton, was an object lesson and an eye opener to hundreds of visitors who had not hitherto appreciated the striking characteristics of the plants. It will be remembered that one of the most charming was *Nymphaea stellata*, two flowers of which are shown in the illustration (fig. 148), that has been prepared from a photograph by Mr. J. Gregory of Croydon. The flowers are of the purest cerulean blue, and have golden stamens, which impart the most exquisite beauty. These flowers rise on stont footstalks to a height of 18 inches above the surface of the water, and enforce universal admiration. In an early issue we propose to give more extended notes of the collection of Water Lilies that forms one of the finest features of the gardens of Gunnersbury House.

NOTES & NOTICES

Recent Weather in London.—There have been thunderstorms in the metropolis during the past few days, accompanied generally by heavy rains. Throughout Monday these conditions prevailed, terrific rainstorms occurring, but no serious damage is recorded. Tuesday was calm, but sunless, and Wednesday opened bright and warm, though occasionally overcast.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, July 3rd, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. On this occasion special prizes will be offered for Roses. At three o'clock a lecture on "Bedding, Hedge, and Pillar Roses" will be given by Mr. George Paul, V.M.H.; and at 4 P.M. a special general meeting will be held to consider the new bye-laws.

Death of a Shrewsbury Arboriculturist.—Mr. W. H. Dove, who lived in Shrewsbury Quarry Lodge, died recently at the age of sixty years. For many years Mr. Dove had had the Quarry under his control, and it was undoubtedly greatly due to his knowledge of arboriculture and taste in the gardener's art that that now delightful place was transformed from barrenness into sylvan and floral loveliness. His death is regretted by a very large number of friends.

Injury to Nursery Stock.—In the case of Cull and Rooke v. the Great Eastern Railway Company an application was made in the Court of Appeal by the defendant company for a new trial or judgment for them. The action was tried before Mr. Justice Grantham and a special jury in March last. It was brought for an injunction to restrain the defendants from permitting their engines to remain stationary at intervals in a siding alongside the plaintiffs' nursery gardens at Coleraine Park, Tottenham, and emitting smoke, smuts and vapours in such a manner as to cause destruction, injury, and damage to the plaintiffs' Vines, plants, and flowers, or from using their engines in such a way as to be a nuisance to the plaintiffs. The plaintiffs also claimed damages. The jury returned a verdict for the plaintiffs, assessing the damages at £400, and judgment was entered accordingly. Mr. McCall, Q.C., and Mr. A. C. Nicoll appeared for the defendants in support of the application, and argued that there had been misdirection on the part of the learned judge, and the verdict was against the weight of evidence, and that the damages were excessive. Mr. Robson, Q.C., Mr. Atherley-Jones, Q.C., and Mr. Crispe appeared for the plaintiffs. We learn from a contemporary that the court ordered that, on the plaintiffs consenting to have the damages reduced to £320, the application should be dismissed.

Royal Meteorological Society.—The second afternoon meeting of this society for the present session was held on Wednesday, the 20th inst., at 70, Victoria Street, Westminster, Dr. C. Theodore Williams, president, being in the chair. Mr. W. Marriott read a paper on "Rainfall in the West and East of England in Relation to Altitude Above Sea Level." This was a discussion of the mean monthly and annual rainfall for the ten years 1881-90 at 309 stations, which the author had grouped according to the altitude of the stations above sea level. The western stations were considered to be those which drained to the west and the eastern stations those which drained to the east of the country. The diagrams exhibited showed that there is a general increase in the annual amount of rain as the altitude increases, and that the rainfall is considerably greater in the west than in the east. The monthly diagrams brought out prominently some interesting features, among which were (1) that the monthly rainfall in the west is subject to a much greater range than in the east; (2) that in the west the maximum at all altitudes occurs in November, but in the east it is generally in October; (3) that in the west the spring months April, May, and June are very dry; and (4) that both in the west and east there is a very great increase in the rainfall from June to July. A paper by Mr. J. Baxendell was also read, giving a description of a new self-recording rain gauge designed by Mr. F. L. Halliwell of the Fernley Observatory, Southport. This rain gauge, which the author believes approaches very closely to an ideal standard, has also the merit of being constructed at a moderate price.

The Cherry Sales.—The annual Kentish Cherry sales concluded on Friday. They made over £30 an acre. Cherries and Strawberries are now being railed to London and the North in large quantities, and according to a daily paper a glut of Cherries this season is probable.

Kent's Strawberries Spoiled.—Kent's Strawberry crop, which partly supplies London and the Midlands with the luscious berries, is being ruined by the heavy rain of the last few days. All the supplies from the open fields are soft and totally unfit for transit, and at Orpington, Swanley, and other centres the whole industry is at a standstill. Thousands of pounds have already been lost, and should the wet weather continue the whole of the outdoor crop will be completely ruined. The growers who raise the best kinds of Strawberries under glass-covered frames are, on the other hand, reaping a rich harvest.

Royal Sympathy and Fruit.—The Queen sent a special messenger to Windsor Royal Infirmary on Friday to inquire as to the progress of the sufferers from the Slough railway disaster, and to ask what would be most acceptable to the patients. Her Majesty was informed through Dr. Farquharson, the house surgeon, that fruit would be much appreciated, and the Queen has therefore ordered a daily supply to be sent from the Frogmore Gardens.

Plum Prospects.—Reports from some of the most important Plum districts in England, including Kent and Oxfordshire, as well as Evesham, now state that there has been an extensive loss of promised fruit as the result of frosts. The crop, therefore, will be a partial one. Cherries are said to have escaped injury, and the "Agricultural Gazette" has seen many plantations in which the trees are thickly covered with young fruit. Early Pears were injured; but Apples at present promise to be abundant. In most districts Gooseberries and Currants show well, and for Strawberries the recent dry and cold weather has not been propitious, though there are great shows of bloom in some places.

Another Lung.—Open spaces in London are being secured wherever possible, and another, the transformed churchyard of Christ Church, Southwark, was declared free to the public a few days ago. Its dedication ceremony was performed by the Bishop of Rochester, supported by the Earl of Meath, who presided, the Rev. A. H. Fontaine, rector, and a large gathering. In declaring the space open for ever, the Bishop said there had been discussion about the propriety of turning consecrated ground into a place of recreation and pleasure. Yet whatever debate had taken place public conscience was perfectly satisfied. Let the highest and lowliest among them remember that they could not do anything higher and nobler than in softening the lot of indigent toilers. What could give greater pleasure in anticipation than the joy of the young and the quietude of the old in having such a beautiful place of recreation? The Metropolitan Public Gardens Association have laid the graveyard out, and St. Saviour's District Board of Works have undertaken to maintain it. Christ Church was founded in 1627. It was erected upon some part of the ancient Paris gardens, famous in their day for bear pits, and for a play-house associated with the stage authorship of Ben Jonson, Marston, and James Shirley.

Richmond Research Laboratories.—An influential deputation waited on Mr. Hanbury at the Treasury on Friday afternoon with reference to the proposal of the Government to erect a National Physical Laboratory in Old Deer Park, Richmond. The deputation represented a number of members of Parliament who are opposed to the proposal, the Corporation of Richmond, and the following societies: Commons and Footpaths Preservation Society, Kyrle Society, Metropolitan Public Gardens Association, National Trust, Selborne Society, Society for the Protection of Birds, and the Kent and Surrey Commons Preservation Committee. It was pointed out that a tacit understanding had always existed since George III. was permitted to close the public rights of way running through the park that the land should always remain unbuilt on. Objection was also taken to the scheme on the ground that the buildings would seriously impair one of the most beautiful views in the neighbourhood of London, and that it would also prevent any extension of Kew Gardens which might become necessary. The site selected for the laboratory almost adjoins the Queen's Cottage Grounds, which was presented by her Majesty to the nation on the occasion of her Diamond Jubilee. It was felt that the amenity of the land thus given to the public would be greatly injured if any building were erected in its immediate vicinity, and expression was also given to the fears of the societies that the many rare wild birds which frequent Old Deer Park would be driven away. Mr. Hanbury promised to carefully consider the views of the deputation.—("Morning Post.")

National Dahlia Society.—A committee meeting will be held on July 3rd, at 4 P.M., in the rooms of the Horticultural Club, at the Hotel Windsor, Victoria Street, Westminster (by kind permission of the members of the club). Agenda:—Election of judges, meeting on September 25th, and other business.

National Amateur Gardeners' Association.—This association will hold its summer display at Winchester House, Old Broad Street, E.C., on Tuesday evening, July 3rd, at seven o'clock. In connection with the exhibition, a conversazione has been arranged, under the patronage of the Lord Mayor of London. The honorary secretary is Mr. V. Stacy-Marks, 1, Anglesea Road, Surbiton, Surrey, who will give any information respecting the association.

National Carnation and Picotee Society.—The annual exhibition of this society will be held at the Crystal Palace, Sydenham, on Friday, July 20th. The Carnations and Picotees give promise of an exceptionally good bloom this season, and a very large display is anticipated. The schedule is a very liberal one, all classes of exhibitors being provided for, four silver cups and about £300 being offered in prizes. The hon. sec. is Mr. T. E. Henwood, 16, Hamilton Road, Reading, who will gladly answer any inquiries respecting the society.

Horticultural Club.—The last monthly dinner and conversazione for the session took place on Tuesday last, 19th inst.; the chair was occupied by Sir J. T. D. Llewelyn, Bt., M.P. The subject for discussion was the "Clematis," opened by a paper by Mr. A. G. Jackman, who was unfortunately not able to be present through indisposition, and the paper was read by Mr. George Bunyard, and an interesting discussion followed. There were present the Rev. W. Wilks, Messrs. H. Selge Leonard, Harry J. Veitch, S. A. de Graaff, P. R. Barr, R. C. Notcutt, R. Pinches, J. Assbee, G. Bunyard, and J. Walker.

Shirley Gardeners' Mutual Improvement Association.—The monthly meeting of the above society was held on the 18th inst. at the Parish Room, Shirley, Southampton, Mr. B. Ladhams, F.R.H.S., presiding over a fair attendance. The lecture for the evening was on "The Cultivation of the Pelargonium," by Mr. H. J. Jones, F.R.H.S., of the Ryecroft Nurseries, Lewisham. Mr. Jones gave an admirable description of the method of treating the Pelargonium. The show varieties of the plant were, he said, introduced in 1690, and though 200 years had elapsed, there was still to be traced a disposition to revert to the original type, the purple or lilac shade. He also gave some useful hints as applying to plants generally, such as get your plants dry when you cut them down. In potting, see that your soil is neither too wet nor too dry. Do not sift your soil through a sieve, as with rough compost the plants do better. In manuring, Give little and often is an excellent axiom, as if you give more than the plant can take it turns the soil sour and you speedily poison your plant. There was a good exhibition of plants, fruit, and flowers. Among the most noticeable were a grand display of hardy flowers from the nurseries of Mr. B. Ladhams of Shirley, containing as it did over 100 varieties, and it well deserved the society's award of merit given to this fine collection. Mr. J. Miles was awarded a certificate of merit for a fine dish of Strawberries, after which a hearty vote of thanks was accorded to Mr. Jones for his most practical and interesting lecture.—HARRY CURTIS, *Hon. Sec.*

The weather has been mostly dull and showery during the past week, with strong winds and cool nights.

Irish Weather.—The weather for the current month has on the whole been fairly summerlike; some of the evenings have been cold, and we have had a thunderstorm followed by heavy rains, but the major portion has fallen during the night time. Our gardens are redolent in beauty, and Roses are abundant. Pæonies are superb, but unfortunately they are mainly the old crimson variety, instead of some of the newer and much improved types of more recent introduction.

Iris paradoxa.

ALTHOUGH this species has been in cultivation for a long period it is still rare, notwithstanding the fact that it is a showy and interesting plant. It belongs to the dwarf rhizomatous section, and in general appearance most closely resembles *I. iberica*. It is a native of the

FIG. 149.

IRIS PARADOXA.

Southern Caucasus. The rootstock is short and sturdy, producing usually from four to six short linear leaves, somewhat crowded. The flower scape is thrown up a little above the foliage, being 6 or 7 inches long. The flowers are large and showy, and vary in colour from very pale blue to purple, more or less streaked with lighter shades. The chief peculiarity of the flower lies in the contrast between the large and showy inner segments and the small inconspicuous outer ones, in this respect differing from most if not all other species. The flowering period is spring. It rejoices in a deep rich loam, but must be in a well drained situation. It should not be deeply planted, and must be placed in a bed of sand when first put out. A place in the rockery or at the foot of a warm wall, where it can be kept partially dry during winter, will suit it admirably. *Iris paradoxa* (fig. 149) was exhibited by Mr. Van Tubergen, Holland, at the meeting of the Royal Horticultural Society held on June 19th, when it was recommended for a first-class certificate by the Floral Committee.

Seedling Verbenas.

HAVING grown these plants on a small scale now for several years past with very gratifying results, I was therefore pleased to see "A. D. K.'s" favourable notice of these plants in last week's Journal. I feel sure they will be more used in future bedding arrangements than they are at the present time. A good strain of seedlings has all the charm and beauty of the named varieties of years gone by, with added vigour and apparently free from that dreaded pest, mildew. I well remember the named varieties that used to be grown, also the trouble and anxiety in getting together a sufficient stock for the required purposes. Then self-coloured ones, such as Purple King, Mrs. Holford, Crimson King, Lord Raglan and Defiance came to the front for distinct colouring, and for a time these held their own, but gradually had to give way to fashion. Then this useful plant eventually fell into disrepute, but, thanks to the perseverance of some of our seedsmen, who probably saw a future before it, and who took it in hand, we are now able, from a packet of seed sown in February, to have strong plants ready for planting at the usual bedding-out time, with the certainty of a profusion of bloom all through the summer season, many equalling and some even surpassing in beauty the original named varieties.—J. EASIER, *Nostell Priory Gardens*.

A Dearth of Peaches.

WHEN I penned my previous notes on this subject I was quite prepared to find it might seem strange reading to many gardeners, especially those who have at times surplus fruit to dispose of, as I know there is often a difficulty in disposing of them at good prices, simply because in districts where Peaches are largely grown the local fruiterers are sometimes overstocked. On the other hand, I have found that in cold localities near large towns Peaches are but little grown in the open air, and not very largely under glass. Shopkeepers have therefore to depend to a great extent upon the London salesmen for their supplies; and although the prices paid are good the grower does not reap the benefit, neither are the fruits so fresh as desirable by the time they reach the consumer. For these reasons I think that those who grow Peaches on a large scale should be in direct communication with shopkeepers in several large towns, and when once a connection of that description was formed they would have a regular outlet for some of their produce. Gardeners who have surplus fruit to dispose of could also adopt the same course, even though their supply was not a regular one. In such instances a "connecting link" seems to be required to put the parties in touch with each other. If any gardeners who have Peaches to dispose of will communicate with me I will put them in touch with a reliable fruiterer who can at all times take good fruit.—H. D., *Victoria Nurseries, West Humberstone, Leicester*.

Preventing the Onion Maggot.

THE suggested use of kerosene or paraffin oil, mixed with sand and strewn about amongst Onion plants to prevent attacks of the Onion fly on the young plants of spring sowings, is not new here, but all the same little is known as to its employment and effects. Practically, the maggot seems to have largely worked its own cure in dying out, for I find almost everywhere fine healthy beds of Onion plants where a few years since it was difficult to keep a plant alive. What is now the case with Onions is not less the case with Carrots, for only a year or two since these roots were destroyed wholesale in many directions. This year the breadths seem to be remarkably good and healthy. It does not follow therefore that when maggot is in evidence nothing to help destroy it should be done, but at least it is evident that there is less cause for worry over the appearance of these insect pests for a year or two than is usually believed.

The Celery and Parsnip leaf mining maggot sometimes is found everywhere doing great harm to these plants, at other times it is seldom seen, and where found easily kept in check. Even the caterpillars that infest Apple trees and Gooseberry bushes give trouble seldom, and may soon be dealt with, but there have been seasons when they have done enormous damage to these fruits. In all cases this year it seems probable that whilst somewhat abundant moisture will greatly assist root action and plant growth, it will also check the production of insect pests. So far as it is now possible to judge Onions and Carrots look remarkably well, and should exhibit very fine crops later. What is advised in America as to the employment of artificial manure dressings by first drawing the soil away from the rows of Onion plants before applying the manures could hardly be adopted in this country. Perhaps out there they allow very wide spaces between the rows, we seldom allow more room than 12 inches.—OBSERVER.

The Oak and the Ash.

OLD saws do indeed die hard; many a time have I heard the old rhyme about the Oak and the Ash. For thirty years I have watched these trees putting forth their leaves, with a view to proving the truth or otherwise of the saying. During the whole of the thirty years I do not remember one single season when the Oak was not out first. I need scarcely say that with trees raised from seed and in all sorts of soils and situations the date of the leaf expansion varies much, and it would be possible in most years to find an Ash in leaf and an Oak somewhere still naked, but taking the general run of trees I have always found the Oak first in the field. However, there is, I believe, a scientific body, which undertakes the recording of the blooming and leafing time of trees, and the secretary would doubtless be able to speak with authority upon this question.—A. H. PEARSON.

The Weather.

I TRUST that "S." has ere now had a share of the rain which seems to have fallen so generally all over the kingdom. He may well rejoice that none of those fierce thunderstorms which did so much harm in portions of Berks did visit Rood Ashton. I hear of one garden in which the huge hailstones destroyed every pane of glass in houses and frames, and in another in which a terrible swill washed 50 loads of gravel from out of a broad walk on to the grass. But the rains of last week were genial and general. Still, the product whilst promoting growth has been a great fall in temperature and a deficiency of sunshine, which is just now so much needed for the Strawberries, Peas, and hay. As a rule gardeners get their share of meteorological troubles, but I think the greatest of theirs can hardly excel that which befalls the farmer when he has a wet hay or corn harvest. Let us hope that we are not in for a wet summer, a grave misfortune to all.—A. D.

Poll or Proxy Voting.

IN speaking of the recently published proposed bye-laws of the Royal Horticultural Society little seems to have impressed itself upon Fellows so much as the suggestion to resuscitate proxy voting. The remarks respecting this are almost wholly condemnatory of the system as regards the R.H.S. and similarly constituted bodies. However, the matter will come on for decision in the course of the special general meeting to be held on Tuesday, July 3rd, in the Drill Hall. Though proxy voting with its many pitfalls may not meet with the favour of the Fellows, there can be little doubt that the present form of open voting is not entirely satisfactory. I would therefore like to bring forward the suggestion of a friend that under certain circumstances poll voting be adopted. As the present open voting stands, a majority of only one out of say a score present at a meeting may carry through the most important measures, and it is to avoid the dangers which may arise from this that poll voting is brought forward. I think it would be far more advantageous and favourable to the best interests of the society if the bye-laws empowered the Fellows to demand a poll where the majority voting in favour of a measure did not amount to two-thirds or more than that proportion of the total present at the meeting. This practice is adopted by many societies, and it is so reasonable and so obviously fair for all parties that it is worthy of the consideration as well of the Council as the Fellows of the Royal Horticultural Society.—F. R.

French Strawberries.

FROM what I have observed sold in the Birmingham market this season the supply of French imported Strawberries have, on the whole, proved superior to that of former years, more especially so far, at least, as appearance goes—a longstanding variety of a very pale and unattractive colour, as well as of inferior flavour, and which generally are packed in oblong boat-shaped boxes in pairs; and though English grown fruit has begun to come in plentifully recently—"Southamptons," to wit—the French supply continues unabated, and finds a ready sale. My principal object, however, in sending these notes is to ascertain the name of the variety in question. Earlier in the season there was also another French variety similarly packed, the berries being much smaller, suggestive of second crop fruit, but bright red in colour, and of fair flavour. The name of this variety, too, would be equally interesting to know. The varieties in question are the only ones I am cognisant of which come from France into the English market, and I have often wondered why far better varieties have not been so produced, and they would be certain of being appreciated accordingly here, and prove more profitable to the growers.

Regarding English produce a fair supply of Royal Sovereign from the Evesham district came into the market last week, the berries being very fine, but owing probably to the comparatively sunless weather, they were unusually acid in flavour, a remark which also applied to the Sir Joseph Paxton supply from Southampton, June 25th.—W. G.

Jottings on Pines.

THOUGH British Pine Apples are discounted by imported they still hold front rank as most ornamental—no fruit ornaments a dinner table so nobly—freshest, most tempting, and best in quality. Of course these matters depend upon the growth and finish, of which from time to time I propose to give brief explanatory details that may be of service to young gardeners, if not to old ones.

When the fruit commences to ripen syringing the plants must cease,

fruit is sufficiently advanced in ripening. The bottom heat should be maintained at 80° to 90°, but the more regular the heat at the roots the better.

The weather, though bright of late, is not yet such as to safely dispense with fire heat, but it will not be required much longer, as the sun heat assisted by that obtained from the fermenting beds rarely allows the atmospheric temperature to fall below 65°, which is more suitable for the satisfactory development of the plants than a higher temperature from fire heat. As recently potted plants make growth quickly, strict attention should be given to ventilation to prevent an attenuated growth, therefore admit air at 75° to 80°, increasing it until

FIG. 150.—RHODODENDRON PINK PEARL. (See page 549).

but the supply of water at the roots should be continued as before when necessary, not being too liberal or the fruit may become black at the core. To improve the colour and quality of the fruit ventilate freely, still not allowing the temperature to fall below 80° in the daytime, gradually diminishing the moisture in the house. Plants of Queens, Enville, and Providence started into fruit last February will ripen this month, whilst Smooth Cayenne and Charlotte Rothschild will require a month longer to finish properly. Under the same conditions they furnish a good successional supply, which may be further extended by removing some of the fruiting plants to a cool airy house after the

85° is reached, and above that ventilate fully, diminishing in the afternoon, closing the house at a temperature of 80°. Afford a light sprinkling daily in the afternoon of bright days.

If a sufficient number of suckers on the early fruiting plants be now selected to meet the demand and started at once, the plants resulting will be suitable for fruiting another season from this time onwards, and prove supplementary to those started in March. The suckers require a low and moist pit, and the shading at this time of year must be effectual, gradually withdrawing it as the plants become rooted, this being indicated by starting into growth freely.—PRACTICE.

The Improvement in Sugar Beet.—It is a well-established fact, says an American writer, that plants can be improved by crossing and judicious selection quite as surely and effectively as the breeding of animals. The Sugar Beet may be quoted as an example of what cultivation may do. The Sugar Beet of to-day actually contains about three times as large a proportion of saccharine matter as it did a century ago.

The Value of Peat.—There will be joy in Ireland and Scotland over the news that comes from Vienna of the latest possibilities of peat. In the Vienna Exhibition of last year there was a building in which everything, from the carpets on the floor to the curtains on the windows and the paper on the walls, was all made from peat. That combustible is now made into fabrics which are said to have the toughness of linen with the warmth of wool, and blankets and other coverings made from it excel in warmth and cleanliness. We may soon look for thriving peat industries in the "congested" districts.

The Advantages of Ivy.—Many people refuse to have creepers of any description on the walls of their houses on the plea that they bring insects into the house. It is a distinct advantage, however, to live in a house with Ivy-covered walls, for the Ivy extracts for its own sustenance every particle of moisture from the brick or stone to which it clings, and thus keeps them free from damp. Then, too, when rain comes the leaves of the Ivy conduct the water from leaf to leaf until it reaches the ground, without the walls receiving any moisture whatever. Then, again, even the most prosaic person cannot but admit how much more picturesque and pleasant to the eyes is a house covered with Ivy than another with bare walls. Even the ugliest and most inartistic building can be made to look quite interesting if Ivy is allowed to find a place on its walls.

Soaking Seeds.—Soaking seeds in pure water has its disadvantages; it dissolves some substance from the seeds, which is brown in colour and gives off the smell of ammonia under heat, showing that nitrogenous matter, which Nature has stored there to nourish the young germ, has been soaked out. The plant grown from seeds soaked in plain water will be weaker and paler in colour than from seeds not so treated. Seeds soaked in water dry very quickly, and the evaporation leaves them drier than before; therefore such seeds frequently fail in a dry soil, or during a period of dry, warm weather. These evil results may be easily avoided by soaking seeds in a solution of some chemical salts of a fertilising nature. Such solution can dissolve little from the seed; on the contrary, it thoroughly impregnates them with fertilising ingredients, so that the young plants appear darker and decidedly stronger. Seeds so steeped always continue moist in consequence of the properties of the saline substance they contain.—("American Gardening.")

Burying Roots.—Ill-informed cultivators have only a faint idea of the reasons why trees should not be deeply planted. It is not because of any injury to the trunks, but because the feeding roots need the oxygen of the atmosphere in the preparation of the food, just as much as the leaves do. So far as the trunk is concerned, burying under the earth is a benefit rather than an injury. If it were possible to have the stems or trunks several feet beneath the surface, and the roots only a few inches, the vigour of the tree would be enhanced thereby. But though this is, says a transatlantic journal, impossible, earth on the surface can be heaped around the trunk to advantage, as long as we do not bury too great a root-feeding surface. This was well exemplified nearly half a century ago by a Peach grower, near Cincinnati, named Bolmar. He had earth by the cartload heaped around his Peach trees. His orchard had the appearance of being covered by miniature stacks. The growth and general health of the trees were remarkable. It was a grand object lesson, and he deserved some recompense. There can be no doubt but that it would be to the advantage of orchardists generally to have mounds of earth around the base of their fruit trees, and it is surprising that such good practice is so generally ignored.

Corsica's Pest of Locusts.—A telegram from Ajaccio states that locusts in enormous swarms have settled upon the district south-west of Bastia. The whole adult male population has turned out to defend the crops. More than 1000 persons are engaged in the struggle, but after three days of ceaseless destruction the invasion remains unchecked, and an appeal has been made for troops to continue the campaign. Had *Le Petit Caporal* been at his native place he would doubtless have preserved his country from such a calamity.

When to Work the Garden.—Cultivating and hoeing in the early morning when the dew is on the earth is far preferable, says an American writer, to doing it in the heat of the day. I arise at four o'clock and breakfast at six in the summer season. In the meantime I devote from one-half to two hours in the garden, hoeing, weeding, cultivating, and gathering cool, crisp Radishes, Lettuces, Peas, Beans, and Beet for the morning and noontime meals. Vegetables gathered when the dew is on them are of the finest quality. Early to bed, early to rise, gives a good appetite for breakfast, and adds days to our lives.

The Growing Interest in Forestry.—The interest manifested in forest matters in the East and Middle West within the last two years has been, says "American Gardening," productive of much agitation and legislation in a number of States. New York State is about to prepare working plans for its Adirondack possessions, while Pennsylvania has passed a forest reserve law and is purchasing land for reserve purposes. In Michigan an Act was passed providing for the creation of a permanent forest commission. Wisconsin also has been agitating forest matters to a great extent, and it is hoped that there will soon be an adequate law enacted for the improvement of forest conditions in that State. Minnesota has enacted a law for establishing forest reserves under a novel plan, from which good results are promised in that State, while in Indiana, North Carolina, Massachusetts, Connecticut, and other States, encouraging progress has been made in awakening general interest in the subject of forestry.

Primula mollis.—Introduced about fifty years ago it was then prophesied that this would be cultivated to a large extent for greenhouse work; that it has never found for itself the place in the affections of horticulturists that its introducers wished is very evident from the few places where it is successfully grown. Probably the reason it is not more frequently seen is that it often does not grow well as a pot plant and so disgusts the cultivator. It is, however, possible to grow it well in a cool house, and it then makes a striking object. A good plan is to raise seedlings in April, and when they have five or six leaves prick them out in a border of peat and loam or light sandy loam. After planting they should be given plenty of room with abundance of air and water until the end of October, when they should be kept on the dry side until growth recommences in spring. When growth is active plenty of water must be given. Under these conditions it is possible to grow plants 18 inches across, with leaves 5 inches in diameter and flower spikes 15 inches high, bearing five or six whorls of rosy purple flowers. If when planted they can be so placed as to be partially shaded by some taller plant, so much the better.—KEWITE.

Reasoning Power of Plants.—Do plants reason? This seems a strange question, but it is asked by the daughter of a prominent Mexican planter who has been making a series of experiments, and publishing the results in a Mexican newspaper. Among the many experiments made by this young lady naturalist of Mexico, the most suggestive was with a Morning Glory plant. This young lady drove a nail in the wall some distance from the tendril of a Morning Glory plant. The tendril at once began to grow toward the nail. The nail was shifted; the tendril shifted its course. Five times the nail was shifted, and five times the tendril shifted its course. Finally a cord was hung up to tempt the tendril, and it shifted its course toward the cord and left the nail which it had five times persisted in following. The young lady asks: How did the plant know that the nail was there? And how did it know that the nail was shifted? When the cord was stretched at an equal distance away, how did it know the difference between the cord and the nail? She also asks: Why do the tendrils of the Morning Glory prefer a cord or continuous support, such as a cord, wire, or lath, or rail, rather than a peg or nail, which does not give this continuous support? Why, when presented with an equal choice between the two, will they invariably choose the continuous support? After asking a series of questions logically springing from the facts cited and others, she concludes by asserting that plants really reason.—("Indian Gardening.")

Calochortus Benthami.

AMONGST the showiest of our smaller growing garden plants must be included the Calochorti, of which we have many very beautiful species and varieties. *C. Benthami* (fig. 151) is a beautiful little Californian bulbous plant, and it is somewhat nearly related to *C. pulchellus*. It is, however, distinguished by its bright yellow flowers, on the surface of the divisions of which are thickly clustered a number of short yellow hairs. It is very dwarf, seldom exceeding 8 inches in height, but is free both in flowering and growth. It is particularly well adapted for growing in pots, and with the protection of a cool frame develops its flowers early in the year, and is much better than when grown in the open border. A charming companion for *C. Benthami* is *C. Maweanus*, which has bluish purple flowers of about the same size as the first named, and similar in habit. This is, however, found near the coast, and in the neighbourhood of San Francisco.

Royal Horticultural Society.

Richmond, June 27th and 28th.

THE exhibition held in conjunction with the Richmond Horticultural Society proved to be worthy of the best traditions of the society. The plants and hardy flowers naturally contribute most, and although the fruit and vegetables were confined to a few exhibits, they were good in their respective classes. The Orchids made a poor show, for the customary exhibitors had staged elsewhere in the other tents.

Fruit Committee.

Present: H. Balderson, Esq. (in the chair); and Messrs. G. Woodward, J. Willard, John Basham, Jas. Smith, Rev. W. Wilks, S. Mortimer, Alex. Dean, Geo. Wythes, H. Esling, A. F. Barron, H. S. Rivers, W. Poupart, Wm. Pope, Geo. Kelf, M. Gleeson, W. Iggulden, J. Cheal, Jas. H. Veitch, and W. Crump.

From Messrs. Suttons & Sons, Reading, came a huge exhibit of Tomatoes in pots, while Gloxinias in variety occupied the rest of the tables; the latter were most tastefully arranged in Maidenhair Ferns, *Ficus repens*, and *Isolepis gracilis*. The Tomatoes were roped with fruit, and included capital samples of Sutton's Al, Tender and True, Sunbeam, Peerless, Winter Beauty, in grand form; Eclipse, Maincrop, and Princess of Wales. The Gloxinias were large, bright in colour, and well flowered (silver Knightian medal). Mr. E. Beckett, gardener to Lord Aldenham, Elstree, exhibited a collection of fifty-five varieties of vegetables, which made a noble show in themselves. The varieties were all good and well grown, those that struck one as being most superior were dishes of Tomatoes Perfection, Sunbeam, Duke of York, Polegate, and Golden Jubilee; Vegetable Marrows Pen-y-byd, Moore's Cream, and Selected White; Beet Crimson Ball; Carrots Scarlet Model, a fine exhibit, and Matchless Scarlet; Potatoes Snowdrop and Sharpe's Victor; Peas Edwin Beckett, a seedling with long dark green pods, Daisy, and Early Morn. Cauliflower Walcheren were splendidly staged, while Cucumber Ideal, French Beans Canadian Wonder and Cabbages Ellam's were all capital so early in the season (gold medal).

Mr. H. Walters, gardener to Lord Gerard, exhibited a collection of Melons, comprising about forty fruits. The varieties were British Queen, Countess, Royal Jubilee, Frogmore Seedling, Hero of Lockinge, a new variety, Eastwell Park, and Scarlet Premier (silver Banksian medal). Messrs. Sutton & Sons staged a new Tomato, Lord Kitchener, a good smooth variety of good colour, and evidently a free setter. Mr. E. Beckett staged a box of Cucumber Ideal, which contained good representative fruits; the variety was granted an award of merit earlier in the season.

Floral Committee.

Present: W. Marshall, Esq. (in the chair); and Messrs. G. Paul, J. Hudson, H. J. Cutbush, W. Bain, C. Blick, W. Howe, C. E. Shea, E. H. Jenkins, H. S. Leonard, T. W. Sanders, R. Dean, H. B. May, J. D. Pawle, J. Jennings, G. W. Miles, C. E. Pearson, J. H. Fitt, Chas. Jefferies, J. Fraser, W. J. James, C. J. Salter, J. F. McLeod, C. T. Drury, and C. R. Fielder.

Messrs. Jas. Veitch & Sons, Ltd., Chelsea, arranged a grand group of Roses in pots, backed with *Lilium Harrisii*, Palms, and Bambusas. The Roses were just in the pink of condition, and included beautiful examples of the Rev. Alan Cheales, Gloire Lyonnaise, La France, Margaret Dickson, Mrs. R. G. S. Crawford, Helen Keller, Prince Camille de Rohan, and Duke of Teck. The flatness was relieved with plants of Electra, the new yellow garden Rose, which were well flowered and effective (gold medal.) A fine bank of hardy flowers were staged by Messrs. Barr & Sons, Covent Garden, which included a good collection

of Pæonies, such as Lord Salisbury, Leonie, Faust, and Maréchal MacMahon. A collection of English Irises was particularly attractive, while Potentillas, Gaillardias, *Heuchera sanguinea*, and *Ixias*, with a variety of other plants contributed to an excellent display (silver Banksian medal). A pleasing arrangement of hardy ornamental shrubs and trees was contributed by Mr. John Russell, Richmond. The colours of the Acers, Ivies, Beeches, and a number of other plants assisted in making an interesting exhibit (silver Banksian medal.)

Messrs. Peed & Son, West Norwood, had a somewhat formal group of Caladiums, for although rather crowded the plants were well grown and the colours most vivid. The chief varieties were Rio de Janeiro, Fastuosum, Her Majesty, and Mrs. John Peed. The groundwork of Maidenhair Ferns were most pleasing. The same firm also contributed a collection of Carnations, which included groups of Princess of Wales, R. H. Measures, Lady Grimston, Mephisto, and Hayes' Scarlet; also a collection of Gloxinias (silver-gilt Banksian medal). Mr. Jas. Hudson,

FIG. 151.—CALOCHORTUS BENTHAMII.

gardener to L. de Rothschild, Esq., Gunnersbury House, exhibited Water Lilies in a most effective manner; in fact, it is undoubtedly Mr. J. Hudson's best effort in this respect. The tubs were surrounded by Water Reeds, Grasses, bracken, and a few clumps of Forget-me-not. *Nymphaea stellata* was covered with open flowers, while *N. marliacea chromatella*, *N. m. rosea*, *N. Robinsoni*, and *N. Laydekeri*, a very natural exhibit (silver-gilt Banksian medal). Gloxinias and Petunias came from Messrs. J. Carter & Co., High Holborn. The double Petunias were full of bloom, and included a good variety of colours, while the Gloxinias comprised a fine strain, the spotted varieties being especially bright and effective. The whole exhibit was arranged with Palms, Lilliums, Maidenhair Ferns, and other foliage plants.

A large expanse of tabling was covered by Messrs. Kelway & Sons, Langport, with Delphiniums, Pæonies, Gaillardias, and a variety of other hardy flowers. The best Delphiniums were Maghull, King of Delphiniums, Albert Edward, Mary Morison, and Dagonet. The most conspicuous Pæonies were Prince of Wales, Baroness Schröder, Lord Cromer, and Duke of Cambridge. Other notable subjects were *Allium glaucum*, *Campanulas persicifolia*, *grandiflora*, and the white variety (silver Flora medal). Messrs. W. Cutbush & Son, Highgate, arranged

a grand group of flowering and foliage plants, somewhat after the style adopted at the Temple Show, and it was quite as effective. The groups of Carnations, with others of *Hydrangea paniculata*, Oranges, Ericas, and miscellaneous plants, with groups of foliage plants arranged in beds of Ferns, *Dracænas*, and other ornamental plants, completed an imposing display (silver-gilt Flora medal). Mr. W. J. Jones, Lewisham, staged a large table of cut Sweet Peas, Zonal Pelargoniums, with a few hardy flowers. The whole table was bright, yet light in arrangement; the Sweet Peas, staged with their own foliage, being especially attractive.

Messrs. G. Jackman & Son, Woking, also contributed hardy flowers in variety, Carnations and Pinks, but the chief feature was undoubtedly the collection of Roses. Those staged in the orthodox style in boxes were clear and fresh looking, while the garden Roses and Penzance Briars were greatly admired, as were also the hybrid Clematises (silver Flora medal). Ferns from Messrs. J. Hill & Son, Edmonton, occupied a table running the greater part of the tent, and the exhibit was a worthy one in every way. The specimens included *Davallia Mooreana*, *Pteris scaberula*, *Platynerium alcinorne*, *Asplenium nidus*, *Cibotium Schiedeii* and *Davallia dissecta*. The smaller plants were all beautifully developed, and included a number of tinted forms so arranged that their beauty could be seen (gold medal). A gorgeous display of hardy flowers was arranged by Messrs. Jas. Veitch & Sons, Ltd., Chelsea. The Irises and Pæonies were especially effective, while *Kalanchoe flammea*, *Rhododendron* hybrids, and *Delphiniums* were notable.

Mr. J. F. McLeod, gardener to J. P. Morgan, Esq., Dover House, Roehampton, contributed a fine group of flowering and foliage plants, tastefully arranged with Ferns, Crotons, Palms, and *Dracænas*. The chief flowering plants were a fine group of Malmaison Carnations, *Lilium Harrisii*, with smaller groups of *Crassulas*, *Clerodendron fallax*, *Statice*, and double *Begonias* completed a splendid exhibit (silver-gilt Flora medal). Mr. W. Poupart, Marsh Farm, Twickenham, staged some typical market produce. The Early London Cauliflower, Polley's Nonesuch Turnips, French Horn Carrots, and dark green Paris Cos Lettuce were excellent.

Large collections of cut and clipped trees with Ivies were arranged by Messrs. W. Cutbush & Son. Mr. J. Buckham, Twickenham, also had clipped Bays, variegated Acers, and Privets as specimen plants, while Messrs. Jas. Veitch & Sons, Ltd., sent an unique collection of Ivies in pots arranged on wire trellis, so that their natural habit could be seen.

Orchid Committee.

Present: H. J. Veitch, Esq. (in the chair); and Messrs. W. H. White, E. Hill, De B. Crawshaw, H. Little, H. A. Tracey, H. J. Chapman, J. O'Brien, H. T. Pitt, and W. H. Young.

Orchids were conspicuous almost by their absence. Mr. H. Tracey, Twickenham, exhibited a good plant of *Cattleya Mendeli albens*, variety Princess of Wales, also a plant of C. M. variety La Belle, a grand form with a parti-coloured lip, the upper portion being creamy white, while the lower part was bright rosy purple. Two *Odontoglossums* were staged by Mrs. Briggs-Bury, Bank House, Accrington, both of which were honoured by the committee, one with a first-class certificate and the other an award of merit.

Certificates and Awards of Merit.

Cattleya Mendeli albens variety Princess of Wales (H. A. Tracey).—A charming variety, with just a tinge of colour at the base of the upper petals, while the base of the lip is shaded yellow (first-class certificate).

Croton Venus (Green, Ltd.).—A narrow leaved variety, yellow, with a little green in colour, and the leaves beautifully curled (award of merit).

Delphinium Sir George Newnes (Kelway & Son).—A deep royal blue, double (award of merit).

Iris Monnieri (Barr & Sons).—This is a handsome Iris with yellow flowers (award of merit).

Nymphaea gigantea (J. Hudson).—A lovely Australian species. The flowers are large, a deep heliotrope colour, approaching blue. A handsome flower (first-class certificate).

Odontoglossum crispum Duchess of Connaught (Mrs. Briggs-Bury).—Flower of medium size heavily marked with cinnamon brown, the lower petals being deeply marked (first-class certificate).

Odontoglossum crispum Empress of India (Mrs. Briggs-Bury).—A variety heavily blotched with purplish-brown, the marking being well defined (award of merit).

Roof Gardens in the City.—It is not often that plants are moved in any wholesale fashion from the smoke and dirt of London to a pure fresh country garden, but such a thing has just happened at London Wall, says the "City Press." A resident, who has been dispossessed by the improvements in that district, while living in London Wall, took a great pride in his roof garden, and year by year possessed a fine show of flowers and plants that flourished in spite of the smoke. These treasures he has moved to the real garden he now possesses, and they serve, as he says, to remind him of the old home, of which he still entertains fond memories.

National Rose Society.

Salisbury, June 27th.

THE southern exhibition of the National Rose Society, which was held in connection with the Wilts Horticultural Society on Wednesday, was a variable one in respect of the quality of the flowers. Some of the examples were of exceptional excellence, while others were decidedly rough; needless to say practically the whole of them showed the effects of the unfavourable weather that we have experienced during the past season. This was of course answerable for the poorness of the competition in the majority of classes. The local exhibition was comparatively small, the best feature being the group of Malmaison Carnations from the Earl of Radnor, at Longford Castle.

Nurserymen's Classes.

The principal class in this section was that for forty-eight blooms, distinct varieties, and the premier position was adjudged to Messrs. A. Dickson & Sons, Newtownards, who staged an excellent box. The varieties comprised Margaret Dickson, Marchioness of Dufferin, Bessie Brown, Ulster, Rubens, Gustave Piganeau, Lady Mary Fitzwilliam, Abel Carrière, Mrs. R. G. Sharman Crawford, Marquise Litta, Mildred Grant, Alphonse Souper, Maman Cochet, Mrs. John Laing, Medea, Lady Moyra Beauclerc, Tom Wood, Deegan's White, Mrs. W. J. Grant, Florence Pemberton, Duke of Teck, Souvenir d'un Ami, A. K. Williams, Alice Lindsell, Marie Verdier, Caroline Testout, Maman Cochet, Madame Hoste, Mrs. Mawley, Souvenir de S. A. Prince, Sheila, Lady Clanmorris, The Bride, La France, Comtesse de Panisse, Marchioness of Downshire, Dupuy Jamain, Hon. Edith Gifford, Helen Keller, Catherine Mermet, Duke of Edinburgh, Marchioness of Londonderry, Mrs. Conway Jones, Souvenir de President Carnot, Gladys Harkness, Maréchal Niel, and Muriel Grahame. Messrs. F. Cant & Co. were second; and Messrs. D. Prior & Son third. There were three competitors.

In the class for twenty-four distinct varieties the prizewinners were Messrs. G. Prince, J. Burrell & Co., and Curtis, Sanford & Co., Torquay, in the order in which the names are here given. The first prize stand contained Comtesse de Nadaillac, The Bride, Mrs. W. J. Grant, Maréchal Niel, Gustave Piganeau, Souvenir de S. A. Prince, Prince Camille de Rohan, Medea, Cleopatra, Souvenir d'un Ami, Rubens, Captain Hayward, Souvenir d'Elise Vardon, Auguste Rigotard, Princess of Wales, Catherine Mermet, Exposition de Brie, Amazone, Lady Mary Fitzwilliam, Kaiserin Augusta Victoria, Marie Van Houtte, Dupuy Jamain, and Innocente Pirola. The second prize box was exceptionally close.

There were four competitors in the class for twenty-four distinct varieties, three blooms of each, and Messrs. A. Dickson & Sons were placed first. The best varieties were Jean Ducher, Madame Cusin, Margaret Dickson, Catherine Mermet, Mrs. W. J. Grant, Mildred Grant, Mrs. Conway Jones, The Bride, Comtesse de Nadaillac, and Tom Hood. Messrs. F. Cant & Co. were second, and Messrs. D. Prior and Son third, both showing blooms touched by the weather. For twelve blooms of any Rose except a Tea or Noisette Messrs. A. Dickson and Sons were first with Ulster in fine form, Messrs. F. Cant & Co. second with Mrs. W. J. Grant in beautiful colour, and Messrs. D. Prior and Son third with the same variety.

The chief class in the Tea or Noisette section was that for twenty-four blooms, distinct varieties. Mr. Geo. Prince, Oxford, was a decided first with Comtesse de Nadaillac, The Bride, Cleopatra, Marie Van Houtte, Maman Cochet, Jean Ducher, Bridesmaid, Maréchal Niel, Niphotos, Souvenir d'un Ami, M. Furtado, Rubens, Medea, Souvenir d'Elise Vardon, Princess of Wales, Souvenir de S. A. Prince, Princess Beatrice, Alba Rosea, Madame Cusin, La Boule d'Or, Innocente Pirola, Anna Olivier, Cornelia Koch, and Golden Gate. Messrs. F. Cant & Co., Colchester, were second; and Messrs. D. Prior & Son third.

The premier award for twelve Teas or Noisettes was secured by Mr. John Mattock, New Headington, Oxford, with a charming box of Ernest Metz, Niphotos, Souvenir d'un Ami, Souvenir d'Elise, Princess Beatrice, Rubens, Princess of Wales, Catherine Mermet, Cornelia Koch, Comtesse de Nadaillac, and The Bride. Messrs. J. Burrell & Co., Cambridge, were second, and Messrs. J. Townsend & Son, Worcester, third. In the class for thirty-six distinct varieties of garden or decorative Roses, not less than three trusses of each, a space of 10 feet by 3 feet was allowed, and there were two exhibitors. Messrs. Paul and Son, Cheshunt, were in the first place with a superb stand. Very conspicuous were Carmine Pillar, Wm. Allan Richardson, Marquise de Salisbury, Gustave Regis, Camoens, L'Ideale, Papa Gontier, and Aglaia. Messrs. G. Cooling & Sons, Bath, were second.

Mr. Charles Turner, Slough, received the premier prize in the class for eighteen garden or decorative Roses with some magnificent bunches, Mr. G. Prince was second, and Mr. J. Mattock third.

Open Classes.

Messrs. A. Dickson & Sons received a gold medal for Alice Lindsell, a Hybrid Tea that promises to be a superb flower. The colour is cream rose. Mr. G. Prince received a card of commendation for a single Rose Bellefleur. The colour is rich carmine scarlet. The first prize in this division for twelve distinct Teas or Noisettes, three blooms of each, was annexed by Messrs. F. Cant & Co., who staged Rubens, Madame de Watteville, Maman Cochet, Souvenir d'Elise Vardon, Madame Cusin,

and The Bride as the best. Messrs. D. Prior & Son were second. For twelve blooms of any Tea or Noisette Rose, Messrs. A. Dickson & Sons were first with Mrs. Edward Mawley in grand condition. Messrs. D. Prior & Son were second with Marie Van Houtte, and Messrs. F. Cant and Co. third with the same variety.

Messrs. G. Cooling & Sons were first for twelve distinct varieties of single Roses with a beautiful exhibit, comprising Yellow Austrian Brier, Rugosa, Rugosa alba, Paul's Single White, Copper Austrian Brier, and Macrantha as the best. Mr. Chas. Turner was second, and Messrs. Paul & Son third. The class for twelve bunches of Sweetbrier Roses brought forth two exhibitors, Messrs. G. Cooling & Sons and Messrs. F. Cant & Co., who secured the prizes as named. Some of the varieties were very beautiful.

Amateurs' Classes.

The premier prize in an extra class, open to all amateurs, for twelve distinct single trusses, consisted of a gold medal and £3, and the position was secured by the Rev. J. H. Pemberton, Havering-atte-Bower. The varieties were Ulrich Brunner, Caroline Testout, Captain Hayward, Mrs. W. J. Grant, Maman Cochet, Duke of Edinburgh, Comtesse de Nadaillac, A. K. Williams, Comtesse de Ludre, Maréchal Niel, Mrs. Sharman Crawford, and The Bride. Mr. A. Hill Gray, Newbridge, Bath, had a neat box with Maman Cochet, Princess of Wales, Madame Cusin, and Maréchal Niel as the best blooms. The Rev. A. Foster Melliar, Sproughton Rectory, Ipswich, was third.

For twenty-four distinct trusses open to all amateurs there was only one competitor. This was the Rev. J. H. Pemberton, and he received the premier award. The blooms were as a whole good, but they showed some traces of the weather. The varieties were Marquise Litta, Madame Joseph Bonnaire, Général Jacqueminot, La France, Capt. Hayward, Caroline Testout, Gustave Piganeau, Mrs. John Laing, Mrs. Sharman Crawford, Duke of Wellington, Maman Cochet, Duchess of Bedford, Mrs. W. J. Grant, François Michelon, Heinrich Schultheis, Chas. Lefebvre, Le Havre, Marchioness of Dufferin, Ulrich Brunner, Jeanie Dickson, A. K. Williams, Marie Van Houtte, Souvenir d'un Ami and Kaiserin Augusta Victoria.

Competitors in the preceding class were eligible to enter that for six distinct trebles, and the leading position was again taken by the Rev. J. H. Pemberton, who staged La France, Maman Cochet, A. K. Williams, Comtesse de Nadaillac, Caroline Testout, and Mrs. W. J. Grant. Mr. G. W. Cook, The Briars, North Finchley, was the only exhibitor in the class for twelve distinct single trusses, open only to growers of less than 1000 plants. The first prize was awarded for neat, clean, but rather small flowers.

For growers of less than 500 plants there was a class for six distinct single trusses, and the first prize was won by Mr. R. W. Bowyer, Haileybury College, Hertford, with a fair box. Mr. F. R. Smith, Melford Lodge, Muswell Hill, was second, and Mr. S. Smith, Warminster, third. An extra class, open only to those in the two just referred to, was for four trebles, distinct. Mr. G. W. Cook was the only exhibitor, and received the premier award with Captain Hayward, Lady Mary Fitzwilliam, Kaiserin Augusta Victoria, and Mrs. W. J. Grant. For six blooms of any Rose other than a Tea or Noisette, open to all amateurs, the Rev. J. H. Pemberton was first with Caroline Testout.

The Prince Memorial cup for eighteen distinct Teas or Noisettes, open to all amateurs, was secured by Mr. A. Hill Gray with Maréchal Niel, Cleopatra, Maman Cochet, Hon. Edith Gifford, Comtesse de Nadaillac, Souvenir d'un Ami, The Bride, Bridesmaid, Princess Beatrice, Madame Cusin, Medea, Souvenir d'Elise Vardon, Princess of Wales, White Maman Cochet, Catherine Mermet, Muriel Grahame, Golden Gate, and Comtesse Panisse. The blooms were superb. The second position was taken by the Rev. A. Foster Melliar.

For twelve distinct single trusses open to growers of less than 500 Teas or Noisettes, the first prize was taken by the Rev. J. H. Pemberton, with Madame Cusin, Souvenir d'un Ami, Comtesse de Nadaillac, Maman Cochet, The Bride, Catherine Mermet, Maréchal Niel, Muriel Grahame, Madame Hoste, Golden Gate, Bridesmaid, and Marie Van Houtte. In the class for six Teas or Noisettes distinct (open to growers of less than 200 plants), Mr. R. W. Bowyer was first and Mr. E. R. Smith second.

For six Teas or Noisettes trebles, open to all amateurs, the prize-winner was Mr. A. Hill Gray. In the open to all amateurs class for six blooms of any Tea or Noisette Mr. A. Hill Gray was first with The Bride, and Mr. S. Smith second with Maréchal Niel. For twelve distinct garden or decorative Roses the Rev. J. H. Pemberton was first with some splendid bunches. For six distinct garden or decorative Roses Mr. Edward Mawley was easily first, and Mr. S. Smith second.

Premier Blooms.

The silver medal Roses in the amateurs' section were:—For the best Tea or Noisette, Maman Cochet, from Mr. A. Hill Gray; for the best Hybrid Tea, La France, from the Rev. A. Foster Melliar; and for the best Hybrid Perpetual, Mrs. R. G. Sharman Crawford, from the Rev. J. H. Pemberton. In the nurserymen's section the best Tea or Noisette was Comtesse de Nadaillac from Mr. Geo. Prince; the best Hybrid Tea, Lady Mary Fitzwilliam, from Messrs. D. Prior & Son; and the best Hybrid Perpetual, Duchess of Bedford, from Messrs. Burrell & Co.

Vignettes of the Veldt.

IN one of his recent war letters to the "Morning Post" Mr. H. F. Prevost Battersby says under this title, "The veldt is a queer country, and only those who have ridden across the sameness of its unchanging miles can claim to know much about it. Yet it has its beauties also, which appear as unexpectedly in the folds of its brown downs as the vivid scarlet petals or pale stars of lemon and heliotrope which grow at wide intervals amid their grasses. One such farm there was on the way to Welgelegen. Four hundred yards to the westward it might have been passed unseen, and even seen across the roll there was but a thin trickle of green where the stream crept down a cleft of the upland, and a green pool of trees about a white-washed house. Yet the dark branches of that pool bore Citrons and Oranges, crimson Pomegranates and purple Figs, and beneath them was a tangle of trailing Roses, great red Hybrids and filmy Briars, with the cream-pink petals and tender yellows of scented Teas. And beside the careless garden walks, under the globes of golden fruit, were flaming Salvias, sulphur spears of Hollyhocks, the dusky copper of great Chrysanthemums, the garnet and white of honey-scented Scabious, and beds of broken purples and gentian blue. One passed from the wide seclusion of the wilderness through the dark grove of Citron and Pomegranate into this sanctuary of flowers. And closer though the seclusion grew, the waste was silent, but the garden sang, filled with the cooing of turtle doves and the bills and fluttering wings of birds."

Fruit Forcing.

Vines.—*In Pots for Early Forcing.*—Stop the canes when from 6 to 8 feet long, pinching the laterals and sub-laterals to one joint as produced. Supply water and liquid manure at the roots as required, and see that the foliage is kept clean by judicious syringing, admitting air rather freely in the early part of the day, as this will favour elaboration and the storing of assimilated matter.

Vines Cleared of Grapes.—Syringe occasionally to keep down red spider, thrips, and similar pests. Afford liquid manure if the Vines are weakly, or water to keep the soil moist. A light mulching of short spent manure will prevent the surface cracking, and the moist surface and nourishment will attract the roots to the surface. Allow a moderate extension of the laterals, and admit air freely above 60°. There is no danger of the wood not ripening; the difficulty is to prevent the ripening and premature fall of the foliage.

Houses of Ripe Grapes.—A good spread of foliage over black Hamburghs and other black Grapes will assist in keeping their colour. Indeed, all ripe Grapes are better for a slight shade from powerful sun. A single thickness of pilchard, or double thickness of herring nets drawn over the roof-lights will mostly be sufficient shade. Moderate moisture will not injure the Grapes if accompanied by free ventilation. Keep laterals fairly under, but a little extension will assist in the retention of the principal leaves, and on their continuance in health depends the maturity of the buds for next year's crop.

Grapes Ripening.—When the berries commence changing colour admit a little air constantly, with sufficient heat in the pipes to maintain a night temperature of 65° and 70° to 75° by day, with 80° to 85° or 90° from sun heat. Avoid an arid atmosphere, damping occasionally, and do not allow the border to become dry. Vines ripening heavy crops will be assisted in perfecting them and storing food for the future by an application of liquid manure occasionally, or a top-dressing of some approved fertiliser washed in, operating in the morning, and choosing a fine day, so that superabundant moisture will be dispersed before evening. A light mulching of dry spent material will assist the Vines by securing uniform moisture and keeping the roots near the surface whilst avoiding excess of moisture, and thus preventing cracking. It is a confined atmosphere that does much of the mischief in Grapes spotting and cracking, therefore leave a little air on constantly and increase it early in the day.

Late Grapes.—Do not delay the thinning of the bunches and berries; overcropping is fatal to perfect finish. Burdening a Vine with more Grapes than it can swell well and evenly is to cause it to ripen the fruit later, and leave doubts as to the berries colouring and having that amount of saccharine matter stored in them which secures their sound keeping. Thin well to secure large and highly finished berries, leaving those of the large-berried varieties about an inch apart, the oval kinds not requiring so much room as the round ones, but all should be thinned.

so that they will have space for swelling without wedging when of full size, and yet be so close that when dished they will retain their form. Loose bunches that show the footstalks are not so pleasing, however fine the berries, as those more compact. Shy-setting varieties are often thin of berries through the number of stoneless ones that must be removed, to guard against which no pains should be spared in getting the wood ripe and in fertilising the bunches when in flower with Black Hamburgh pollen or that of other free-setting sorts. A pound of Grapes per foot run of rod is usually as many as most Vines can finish well.

Regulating the Growths.—Allow all foliage to remain that can have full exposure to light, but when the space is fairly covered with leaves keep the shoots closely pinched. An excess of foliage is not good, though it is often encouraged with a view to root action, but it is elaborated juices that build up the structures of the Vine, the crop of the current year, and the wood and buds that give the fruit of the next. The foliage should be rather thinner in the case of white Grapes than in black. This more particularly applies to Muscats, which of all Grapes require high elaboration of the sap to insure their assuming the rich golden amber so much prized. Avoid large reductions of foliage at a time; it only tends to induce shanking through the check given to the roots.

Keep the growths tied down from the glass, and so prevent scorching. Vines extending must be allowed to make as much lateral growth as practicable, always bearing in mind the wood on which the fruit is to be borne next season must have full exposure for its foliage, as it is the principal leaves that elaborate the sap and transmit the assimilated matter that forms the buds at the base. The laterals from these having been stopped at the first joint, may be allowed to extend afterwards, subject to their not interfering with the access of light to the main leaves.

Temperature and Ventilation.—All late Grapes thrive best in a high temperature, with abundant food at the roots and a genial atmosphere. Fires should be employed to maintain a night temperature of 60° to 65°, and 70° to 75° in dull weather by day. Admit air early, allowing a little ventilation at the top of the house constantly, increasing the ventilation with the temperature. Advance to 85° or 90° with sun heat, at which keep through the day by that means, reducing the ventilation with the declining sun. Close at 85°, damping the paths well, then again before nightfall. It is well to close for a short time, and afterwards admit a little air, which will prevent a vitiated atmosphere. Make the most of sun heat for late Grapes by judicious ventilation, aiding with artificial heat so as to keep them in steady progress; avoid cold draughts or sudden depressions of temperature, as these cause rust and favour the spread of mildew and other pests.

The Kitchen Garden.

Asparagus.—Peas are late this season, and not till they are fairly plentiful is it possible to wholly cease cutting Asparagus. It should, however, be remembered that a strong early top growth is imperative if extra stout shoots are desired next spring; a very good reason why there ought to be no undue delay in ceasing to cut. In hot, dry positions it pays well to give the beds an occasional soaking of liquid manure, or to water in a light surfacing of guano or some other soluble manure. A mulching of strawy manure is also beneficial.

Broccoli.—Only sturdy, short-stemmed plants will survive a moderately severe winter, and these may be grown without any great difficulty. A bad start is made when the plants are raised thickly in seed beds and left in these till they have become leggy and weakly. They ought to be got out early on firm, moderately rich ground. The autumn varieties may be planted between rows of early Potatoes disposed 3 feet apart. The later varieties should be planted 30 inches asunder in the open on ground made firm by trampling.

Borecole and Brussels Sprouts.—These important crops should have a rather long period of growth. They may be planted between rows of early short-topped Potatoes soon after these have been finally moulded up. Those previously pricked out in nursery beds ought to be watered, and a little later transplanted, each with a ball of soil about the roots. Plants in seed beds should be watered, after which they may be lifted and replanted with a dibber. Water immediately after planting, and occasionally till growing strongly. Those on specially prepared ground may be 2 feet apart in rows not less than 30 inches asunder. Seeds of Asparagus or Buda Kale may yet be sown thinly in drills 2 feet apart, and if only slightly thinned a heavy crop of greens will probably be available next spring.

Cauliflowers.—These have not been an unqualified success this season. The smaller hearts may be considerably increased in size if the plants receive abundance of liquid manure. Later breadths of the Autumn Giant planted on moderately rich ground may be found of good service in October and November; also for storing in pits and frames.

Runner Beans.—The seeds of these having germinated evenly there are many more plants than ought to be left; crowded plants are the first to fail in a dry hot season. Thin out to a distance of 1 foot apart, one plant to each stake being ample. Those to be grown without stakes must be kept closely topped.

Book on Orchid Culture (J. C. S.).—The book to which we made reference was Burberry's "Orchid Growing for Amateurs," published by Messrs. Blake & MacKenzie, Liverpool. You will find it most useful as an aid to the culture of small collections.

Apple Trees not Bearing (J. W.).—The growths are weak, and the blossoms, or remains of them, too feeble to produce good fruit even if setting. Neither the foliage nor the flowers appear injured, and there is no evidence of disease. As there may be mildew we should add a little flowers of sulphur to the water used in syringing the trees, first moistening it or forming it into a paste with skim milk, then place about a tablespoonful of the paste in a pailful (3 gallons) of water. To invigorate the trees supply at once a top-dressing of the following mixture:—Bone superphosphate, dry and crumbling, 9 parts; nitrate of potash, finely powdered, 6 parts; nitrate of soda, crushed fine, 7 parts; and sulphate of lime, well grown, 7 parts; mix and apply at once at the rate of 4 ozs. per square yard from the stems outwards to about a foot beyond the spread of the branches. In the spring, when the buds commence growing, repeat the application, and probably next year, or the year following at most, you may be rewarded with a good crop of fruit.

The Prophet Flower (L. P. C.).—The Arnebias are usually known as Prophet Flowers, though there is no apparent significance in the term. They are not very widely grown at present, but will become more

FIG. 152.—ARNEBIA CORNUTA.

popular. Few rock plants are more attractive in early summer, the flowers being borne in great profusion. Some of the flowers have dark spots and others without them, or with lighter marks; it is a peculiarity of the Arnebia that the spots with which the flowers are distinctly marked when they first open gradually fade with age, and finally disappear before the flowers wither. The latter are pale yellow in hue, and a vigorous plant in a sheltered nook on the rockwork is very bright and pleasing. Arnebia echinoides succeeds better in a somewhat shaded and sheltered position in the rock garden than when occupying an exposed site. Ordinary soil will do if well drained. The plant grows 15 to 18 inches high. A. cornuta (fig. 152) is of more recent introduction than A. echinoides, but the colour, yellow with a rich velvety brown patch, is similar to that of the latter.

White Dutch Currants on Ribes aureum Dying at the Union.—(R. W. G.).—There is no trace of fungus as you suspect, though the bark of both scion and stock is destroyed round the stem at their junction, and this is the cause of the death of the White Currant, the stock, or Ribes aureum, being quite sound immediately below in both wood and bark. The disease resembles that occasioned by bacteria, and known in the United States as "fire blight." The bacteria, named *Micrococcus amylovorus*, probably gained access by the wound made in working the Currant on the stock, a cavity being formed holding water and thus providing the needful moisture. We do not consider Ribes aureum too strong a stock for White Dutch Currant grown as a standard; indeed, we have seen some fine plants on that stock.

Cucumbers not Swelling (L. G.).—When the leaves of Cucumbers or other plants are burned or otherwise seriously injured, the roots are seriously affected in proportion to the extent of the injury. They cannot imbibe food as before, and if they could it would be crude and non-nutritious in the absence of leaves to purify it and fit it for promoting healthy growth. If you water plants with few leaves exactly as you do others with many, either the healthy do not have enough or the injured too much. The supply must be in accordance with growth. When the plants produce stout healthy leaves like the others, as they may do under careful treatment, the fruits will no doubt swell; but if the plants are much injured, and do not make new growth freely, it will be advisable to train shoots from the others for gradually occupying the space which otherwise might not be usefully turned to account. We have seen a Cucumber plant cover a roof 20 feet by 15 feet, and bear abundantly throughout; but, as you may imagine, the roots were well fed with frequent surface dressings of rich turfy loam and plentiful supplies of water alternating with liquid manure.

Iris Leaves and Roots Diseased (T. M.).—The leaves and crowns of the rhizomes are infested by a fungus closely allied if not identical with *Botrytis galanthina*. The disease is said to be induced by the plants or clumps being grown too closely, and through having the plants on the same ground for a number of years. The disease attacks the leaves and passes down to the crowns, destroying these at the junction with the rhizomes, and in consequence the growths are destroyed, even the rhizomes or root-stocks decaying. The best preventive of the disease is to give the plants a change of ground occasionally, and not to use the feeding material in a raw but a well decomposed state. It has also been found advisable to use occasionally, especially in the early spring, a top-dressing of fertiliser, such as the following: superphosphate of lime twelve parts, nitrate of potash seven parts, nitrate of soda nine parts, sulphate of lime nine parts, mixed; apply $\frac{1}{4}$ lb. of the mixture per square yard in the spring, sprinkling on to as well as about the plants, but first lightly covering the rhizomes with some thoroughly decayed rich material. It should be applied by or before the plants commence growing. As regards cure, we suggest the removal of all the diseased parts, cutting cleanly and burning them. Afterwards dust the plants by means of a bellows apparatus with a fungicide in powder containing sulphate of copper.

"Insects" from Vine Border (H. N.).—The specimens you have submitted are fine ones of snake millipedes, *Julus terrestris*, one of the British species, as to whose harmful propensities there can be no doubt. It is a general feeder, consuming both decaying and living substances. It usually attacks plants at the roots, eating the tender rootlets, and in particular it feeds upon root crops—Potatoes and Carrots. It also feeds upon the fleshy rootlets and even crown stems of Strawberries, being particularly fond of the fruit. On a Vine border it chiefly does harm by the larvæ feeding on the young, tender, spongy roots, the adults also being equally partial to them. No doubt the pest has been encouraged by the decaying vegetable matter and manure, and the removal of these may be an advantage in getting rid of the pest. But we should have tried the effect of soot, which is known to either kill or drive the millipedes away, a peck being the proper quantity to apply per rod. Nitrate of soda finely crushed has also been used with good results, an ounce being applied per square yard. The soot is sometimes applied in liquid form, two handfuls of soot being used to a gallon of water; also the nitrate of soda dissolved, 1 oz. to a gallon of water. The paraffin oil, one to fifteen parts water, will no doubt have given them a dose they are not likely to recover from, but it is not a good application for the roots of Vines. The millipedes are very fond of cotton cake, hence this has been used to attract them to the surface of the soil, and then the border may be watered with a solution of Little's soluble phenyle, a wineglassful to three gallons of water, giving about as much as watering a seed bed.

Names of Plants (T. A. J.).—1, *Centaurea cyanus*; 2, *Veronica rupestris*; 3, *Weigela rosea*; 4, *Geum coccineum flore-pleno*; 5, *Iberis sempervirens*; 6, *Viburnum opulus*. (F. K.).—*Hieracium giganteum*. (M. W. P.).—1, a form of *Cattleya Mendeli* that is well worthy of preservation; 2, *Miltonia vexillaria*; 3, *Epidendrum vitellinum*; 4, *Cochlioda Noezliana*. (M. G. R.).—1, *Salvia argentea*; 2, *Cypripedium Lawrenceanum*; 3, *Asplenium viviparum*; 4, *A. biforme*; 5, *Microlepia hirta cristata*; 6, *Adiantum cuneatum grandiceps*. (F. C. B.).—1, *Maxillaria tenuifolia*; 2, apparently a bad form of *Odontoglossum gloriosum*; 3, *Oncidium sphacelatum*; 4, *Masdevallia Pescatorei*; 5, *Jasminum gracillimum*.

Implements at the Royal Show.

MACHINERY already plays such an important rôle in the work of every well managed farm, and every year makes the farmer so much more dependent upon it, that the implement department of the great national show is constantly becoming of greater public interest.

We are glad to find that the amount of shedding occupied shows a large increase on last year, and is much above the average, as are also the number of exhibitors and exhibits. This shows that notwithstanding low prices of farm produce the trade for farm implements

is encouraging enough to induce manufacturers to extend their production.

A day intelligently spent amongst the machinery at a big show is always a day well used, and one by which the farmer may obtain much useful knowledge, even if he buys nothing, whereas if he be inclined to criticise as well as inquire, the engineer or machine maker may pick up many a hint in return from his practical knowledge. There are £200 offered in prizes for machinery, and the exhibits are thus classified:—

Horse power cultivators	18
Steam diggers	2
Milking machines	2
Sheep shearing machines	11
New implements for medal	50

Amongst the novel implements is an entirely new invention, just brought out by Messrs. Ashley & Sons of Louth. It is a mill for grinding corn, crushing maize, and splitting beans. The grain is first dealt with by a combination of grinding discs, which bring it to a three parts ground condition; it then passes through the stones and is reduced to meal. A great saving of power is claimed for this process.

Messrs. Sargeant & Co. of Northampton sent a novelty in the shape of a drill named the "Victor." The object of this tool is the simultaneous sowing of grain and artificial manure, whilst not allowing the two to come into immediate contact. This end is obtained by having two sets of coulters; the first row open a number of small furrows and deposit the manure therein, the other set following behind and passing between these furrows fill them up, covering the manure and leaving the grain between them and not in contact with the fertiliser. The advantage in this drill is in completing two sowings at one operation. We should prefer manure to be broadcasted and harrowed in, either before or after the grain drilling, as we are sure manures cannot be too much distributed.

A new implement of great ingenuity and which is attracting attention is a patent automatic electrical horse feeder, and was exhibited by Messrs. Thomas Wood, Miles & Co. of Bristol. The apparatus is so constructed that it can be worked by an alarm clock or by pressing an electric button. One or any number of horses may be fed at a given moment, the feed having been prepared and put into one or more overhead feeding boxes; when the appointed hour arrives or the button is pressed the boxes are reversed and each deposits its contents in the manger. Much difference of opinion was expressed as to the utility and value of this invention, but we venture to think that it will obtain a favourable verdict in the long run, for now that horsemen are so difficult to obtain and still more difficult to get out of bed at a time when horses should have their morning feed, any apparatus which will make these animals independent of the sleepiness or otherwise of the farm servant will be a benefit to them, and through them to their owners. Apart from farm horses, it should commend itself to public companies and all owners of horses who expect their animals to be at work at an early hour. This apparatus was only exhibited for the first time three weeks ago at Bath.

Another new machine that deserves notice and which attracted a good deal at the show, is the new patent swath turner, exhibited by Messrs. Blackstone & Co. of Stamford. This machine with its two forks turns two swathes; one is turned clear of the road wheel, and the other on to the track over which the horse has passed—i.e., the space between the swathes before being turned. Each swath is turned on to dry ground previously unoccupied. The Clover or hay is left in a wonderfully light condition for drying, and as one machine will take the place of a large number of men, the money saving must be considerable, besides which there is the greater expedition with which the crop may be harvested, thus minimising the risk of damage from rain.

Anything which tends to remove elements of danger is to be commended, and when we think of the many accidents with chaff cutters which have come under our own observation, we cannot but express our pleasure that no less than three new cutters, built with special view to the safety of the man feeding, have been shown at York, the exhibitors being Messrs. Richmond & Chandler, Messrs. Bamford and Sons, and Messrs. Kelsey & Son of Sheffield.

Messrs. Bamford's cutter practically feeds itself, the material to be cut being simply thrown into a wooden trough, and it is not necessary for the man to put his hands in at all. There is also an automatic apparatus, which throws the cutter out of gear if it is strained by overfeeding. When noted ploughmakers like Messrs. Howard of Bedford, and Messrs. Cooke of Lincoln both take up a new idea there should be something in it. These firms are exhibiting, as novelties, ploughs to ridge three rows at once; Messrs. Cooke's is also described as an earthing plough. As regards the ridging, one thing gained by such an implement should be greater equality in the width of the ridges, and if it be found to save horse or manual labour as well it should come into general use. We should be more doubtful as to its utility for earthing up purposes.

We have always had a good feeling for Messrs. Lankester since we bought that very satisfactory little Iron Age hoe from them, and we trust that they are not promising too much with their new hay loader. This loader is attached to a farm waggon, and will take up the hay from a windrow, but not out of cock. It is supposed to be able to load a ton of loose hay in five minutes, and do it more cleanly than hand labour. A public trial of such a machine would be very interesting and we should like to see one.

A difficulty in connection with spraying machines worked by horse power has been the liability of the air vessel to burst owing to a too sudden increase of speed on the part of the horse. Mr. G. F. Strawson has invented a new automatic safety gear which prevents this and regulates the pressure up to which it is desired that the machine shall work.

The prizes for horse power cultivators were awarded, first to Messrs. Harrison of Stamford, second to Messrs. Coleman & Morton of Chelmsford. For steam diggers, first prize The Cooper Steam Digger Co., Kings Lynn. For milking machines no prize was given, the machines being considered open to much further improvement, and the judges suggested renewed competition at some future time. In the two classes for sheep shearing machines there were eleven entries, and the prizes for both mechanical power and hand driven machines went to the same parties, the Barton Gillette Co. Messrs. Kelsey received a silver medal for their new safety apparatus in connection with their chaff cutter, and another was awarded to the Milwaukee harvester and binder.

Work on the Home Farm.

The Royal Show week, as usual, brought with it showery weather, and would-be haymakers are anxiously waiting for a rising barometer before venturing to set the grass mower to work. The crops have improved a little with the heavy showers, but Clovers have always been too thin on the ground to make good crops of hay, and it is impossible to improve them now. Hay is just a fair crop, and will be of good quality if well got. It has plenty of bottom grass, but is short. We do not think it is advisable to wait for fine weather before cutting; farmers have to take risks bigger than this, and we have noticed that if we cut in showery weather we very often had fine weather to follow. Then there is the second crop to consider, for the earlier the first crop is harvested the more valuable will the second be for the lambs during the critical month of August.

All crops show great improvement, Barley especially, as it delights in warm showers about midsummer. Turnips, which a week or two ago were suffering in a few cases from fly, are now growing rapidly, and will get on quite as fast as the majority of farmers will want them, for farm hands are as scarce as ever. A few old Wheat stacks are still to be seen. As prices have varied very little during the last six months, holding Wheat must have been an expensive game to play. There should be no reason for delaying thrashing any longer if the necessary hands can be got, unless the Chinese trouble should lead to a European war. We fear that the stacks will not be worth much if they are kept until such an event takes place.

We see that the Meteorological Office is offering to supply daily telegraphic forecasts of the weather to persons desirous of having them during the harvest season. The charge will be 6d. per diem, and an equivalent charge for portage where necessary. Applications for the forecasts, stating the period for which they should be supplied and particulars as to the shortest telegraphic address and portage, should be sent to the secretary, Meteorological Office, 63, Victoria Street, London, S.W. Surely one farmer at least in every parish ought to avail himself of this cheap information. We have found an evening paper with the day's cricket in it very useful in attempting to forecast the next day's weather; but the information at the command of the weather office is of a far wider nature than that, and covers thousands of miles; and the farmer should have the forecast in his hands before his men leave work for the day.
